MANUAL OF FORESTRY.—Dr. SCHLICH's *Manual of Forestry* has, we are glad to see, rapidly attained to the dignity of a "classic." The fourth volume of the manual devoted to forest-protection is now before us in a second edition (BRADY, AGNEW & Co). This is the work of Mr. FISHER, and consists mainly in a free translation of Dr. HESS' German work entitled *Der Forstschutz*. Mr. FISHER is more than competent to have given us an original work suited especially to British requirements, but in any case those interested in forestry are under great obligations to him for what he has done. The subject matter deals with the necessary protection of forests, and it is humiliating to find that "protection against man" occupies so large a portion of the volume. The protection of the forest against animals of all kinds also fills a large portion of the book. The description of the various insects and fungi destructive to forests is very valuable and should be in every forester's office for reference. Atmospheric and climatal influences are also discussed, so that the whole forms a treatise which will be of the greatest service to every practitioner. The fact that it is in a second edition confirms our assertion and absolves us from the necessity of alluding in further detail to its contents.

Publications Received.—*Notes sur les Orchidées du Brésil et des Régions Voisines*, par Alfred Cogniaux, Etat Independent du Congo. *Enumeration des plantes récoltées par Emile Laurent*, par E. de Wildeman. Fascicule IV., pages IX.-CXX., and 355-450; pl. CVII.-CXLI. — *Bulletin du Jardin Impérial Botanique de St. Petersburg*. Tome VI., Livraison 5-6. — *Life and Flowers*, by Maurice Maeterlinck. George Allen. — Board of Agriculture and Fisheries, Leaflet No. 180. Dodder. — Leaflet No. 182. *Crimson Clover*. — Agricultural Statistics, 1906. *Return of Produce of Crops in Great Britain*. "Judging by the yield per acre, 1906 ranks as one of the most satisfactory years on record for the principal farm crops. Every crop, with the exception of meadow Hay and Hops, was returned as above the average." — *Photographic Monthly*. March. An article herein by Mr. Crabtree suggests that panchromatic photography may be widely used in the future for flower-photography. — *The Garden City*. March. Includes a highly satisfactory report of the association during 1906. — *Schedule of Prizes and Rules of Southend-on-Sea and District Horticultural Society*. Summer show, 10th July, Chrysanthemum show, 5th and 6th November.

JOHN GILBERT BAKER, F.R.S. (VEITCH MEMORIAL MEDALLIST).

ing *P. decussata* and 51 varieties mentioned in the journal of the R.H.S. 1902, p. 649. Phlox pilosa is mentioned as the first of the genus to be cultivated in England under the name of trumpet-flower at the end of the 17th or the beginning of the 18th century. A large number of garden forms of *P. Drummondii* is also tabulated. Gilia, including *Leptosiphon*, is treated in the same way, the author being comprehensive in his definition of genera but analytic in his treatment of species. A very comprehensive index is added, so that the book will be most serviceable to the student of this family who is interested in the cultivated forms as well as in the mild types.

DILLENIUS.—The Oxford University Press has published the *Dillenia Herbaria*: an account of the Dillenia collections in the Herbarium of the University, together with a biographical sketch of Dillenius, selections from his correspondence; notes, &c., by G. CLARIDGE DRUCE, Hon.M.A., Curator of the Fielding Herbarium, edited, with an introduction by S. H. VINES, M.A., F.R.S., Sherardian Professor of Botany in the University.

dium have each over 100 representatives in Brazil, while there are 44 species of *Catasetum* and 89 species of *Cattleya*. Brazil is so vast, equal to 5-6ths of the area of Europe or fifteen times larger than France, that extensive districts are still botanically unexplored. This is particularly the case in the provinces of the centre, the west, and the north, so that no doubt many additions have yet to be made to our knowledge of its Flora. In the meanwhile the gratitude of botanists has been more than amply earned by M. COGNIAUX, who modestly speaks of his 15 years' labours as being as little incomplete as he could make them.

GARDENERS IN THE UNITED STATES.—At this season of the year and far into the spring, there is a continued demand for young men as foremen and assistants on private estates. Unfortunately there are more positions than there are young men to fill them. [How different to the conditions here. —Ed.] While it is against the contract labour law of the United States to employ any one from foreign countries direct, any young man coming to New York at this season of the year would have no difficulty in securing a position and obtaining

VEGETABLES.

NEW ASPARAGUS BEDS.

ALTHOUGH well-prepared beds of Asparagus, if kept free from weeds and top-dressed yearly with rich manure, salt, and an occasional sprinkling of nitrate of soda, will produce good "heads" in plenty for a great number of years, it is nevertheless advisable to renew certain of the beds at intervals. In some gardens the soil is naturally adapted to the growth of Asparagus and very little more is needed to produce satisfactory "heads" than good culture, but when the land is clayey, stubborn and ill-drained, much needs to be done if a good crop is desired. A rich, deep, sandy loam, containing some well-decayed manure, suits Asparagus, therefore, if the soil is of a stiff, heavy nature, it should be thoroughly drained—for nothing is more fatal to the plant than stagnant moisture—and well cultivated to a depth of 2½ feet. When preparing the ground for planting, set out the beds with stakes, allowing a width of 6 feet for the bed, which will be sufficient for planting three rows. Next dig out the soil to the required depth; if the land is wet, 2½ to 8 feet will not be too much, and if it requires draining, place a couple of drains in the trench the whole length of the bed. At the bottom of the trench place a layer of about 9 inches of old broken bricks, clinkers, or similar material, and on this several inches of long manure. If the soil is of a heavy nature, mix plenty of road scrapings, leaf-mould, or other material that will lighten it, and add sweet manure to the soil as the filling of the trench proceeds. The bed should be raised several inches above the ground level. Although the best time for making new beds of Asparagus is in the autumn, they can also be prepared, with success, in March.

I have just prepared two very large beds on land that needed no artificial drainage, nor the addition of any material for lightening its texture, it being naturally light and full of grit. The site was staked out, the soil opened to a depth of 15 inches, and the subsoil was trenched for a depth of 18 inches. Some manure was incorporated with the subsoil, and over this was placed a good layer of rotten manure, and next about 6 inches of the soil with a sprinkling of salt. The bed was made 9 inches above the ground level, and the surface soil may be turned over again before planting, but this will be decided upon later. I intend planting three rows of Asparagus in each bed, and this will allow a space of 2 feet between the plants each way. Planting will be done at the beginning of April, just as the young growths are developing. Cultivators who wish to raise their own plants can sow the seeds in drills drawn 8 inches deep on the beds where they are to remain. When large enough thin the plants to the required distance. The seeds can also be sown in boxes, in which case they should be dropped into holes 3 inches apart, and their germination hastened in frames to ensure the seedlings being ready for transplanting in May. *H. Markham, Wrotham Park, Barnet.*

KALES AT WISLEY.

THE following members of the Fruit and Vegetable Committee of the Royal Horticultural Society, Mr. W. Bates (chairman); and Messrs. Lyne, Willard, Beckett, Reynolds, H. J. Wright, Foster, Jaques, and A. Dean journeyed to Wisley Gardens on Friday, 8th inst., to inspect a trial of Kales. The whole of the plants of the broad-leaved or Buda, and the Asparagus sections had succumbed to frost or disease, and, remembering how some years ago a fungoid attack swept off all this section of Kales at Chiswick, the general opinion was that fungus (bacterium) and not the weather was the primary cause of failure. The taller and stronger-growing broad-leaved types, including Chou de Milan, Thousandhead, and Jersey Cabbage were comparatively unharmed, and of

these the Chou de Milan was the best, although it was not a really good stock. Next were inspected three stocks of cottagers' Kale, and of these the best was one having a greater proportion of green leafage than the others, and a more compact habit. Some hearting Kales seen were not in good condition, and they did not commend themselves to the committee. Neither did the few stocks of variegated Kales, nor the purple curled Kales. Of this latter type, undoubtedly the best was the dwarf purple variety Arctic. A very curious and novel Kale is Chou de Russie. This forms almost hearting heads of deeply cut or laciniated leafage, and produces sprouts in great profusion on the stems. It was selected by the committee for award (see p. 195). The Scotch curled green Kales were numerous, and these included both tall and dwarf forms. A breadth of the old tall Scotch variety showed how greatly improved were the modern stocks of this type. Ultimately, the following varieties were recommended for Awards of Merit:—Tall green Scotch (James Veitch & Sons); Dwarf Moss, green curled (James Carter and Co.); Cottagers' Kale (James Veitch & Sons), Chou de Russie (James Carter & Co.); and Selected Medium, green curled (Kent and Brydon). Afterwards the committee inspected the gardens generally. A sowing of some 150 stocks of Onions has been made for comparison and trial. Ground has also been prepared for a trial of Cactus Dahlias. Special interest was displayed in a bush of *Erica lusitanica* codonodes, 6 feet in height, in full bloom, and in the young vines in the new viney, all of which have made fine rods with short joints. *A. D.*

TREES AND SHRUBS IN SCOTTISH GARDENS.*

(Concluded from page 169.)

MONREITH.

Monreith is situated near the end of the promontory in Wigtownshire that juts out towards the Isle of Man, between Luce Bay and Wigtown Bay. Being almost on the extreme south-west of Scotland, with water on three sides, the climate is necessarily mild and moist, and suited to many forms of tree and shrub growth. How rapidly some of these grow will be seen from the following notes. Monreith is the home of Sir Herbert Maxwell, who, among his many interests, regards forestry, I believe, as not the least.

Pinus insignis, planted in the winter of 1883-4, is now 65 feet high, its growth clean and erect, and that of a single year sometimes over 4 feet in length. *P. monticola*, planted in 1875, is 63 feet high and 4 feet 5 inches in girth. *Cupressus macrocarpa*, planted less than thirty years ago, is 60 feet high, with a trunk 7 feet 5 inches in girth—a model of health and vigour. These three trees are perhaps the most notable examples of rapid growth, but other evidences of the generous climate are to be seen in the fine trees of *Thuja gigantea*, *Juniperus virginiana*, *Cupressus* (*Chamaecyparis*) *nootkatensis*, *C. sempervirens*, and *Abies nobilis*. In some plantations of Scots Pines and Larches made by Sir Herbert a few years ago it was interesting to note that a few specimens of the Japanese *Picea ajanensis* were making the best headway, the "leads" of some this season being already over 2 feet long. *Abies Nordmanniana*, although it evidently grew well in its early days, has proved a failure owing to the attacks of a scale insect and of a fungoid pest—*Peridermium elatinum*—which causes curious gouty, barrel-shaped protuberances on the branches.

There is a charming old-fashioned garden attached to the house where are growing some striking shrubs. I noted *Rhododendron barbatum*, *Chionanthus virginicus*, 10 feet high and as much through, and *Olearia Haastii*, 9 feet high and 15 feet through. *Lilium giganteum* is perfectly at home here; one spike I saw carried twenty flowers.

* Contributed to the *Kew Bulletin of Miscellaneous Information* by Mr. W. J. Bean.

CASTLE KENNEDY.

Castle Kennedy is close to Loch Ryan, in Wigtownshire, and a long way to the south-west of Perthshire. The climate, whilst equally moist, is considerably warmer, and a different class of trees and shrubs is growing here. *Escallonias*, for example, especially *E. macrantha*, thrive as well as they do in Cornwall, and are evidently held in about the same esteem as Laurels in less favoured places. Callistemons were flowering freely, and *Eucalyptus Globulus* was 35 feet high. *Olearia macrodonta*, which I saw so fine at Inverewe, in Ross-shire, was here equally good. The prevailing type of *Rhododendron* is Himalayan, either the pure species (especially *R. arboreum*, *R. Thomsoni*, and *R. campanulatum*) or hybrids in which their "blood" predominates. A further evidence of the character of the climate was afforded by *Richardia africana* growing in an open pond, and flowering freely.

I should think Castle Kennedy is one of the best watered inland demesnes in Britain. The gardens are situated chiefly on a neck of land between two lochs known as "Black" and "White" respectively, and there are several ponds and minor pieces of water besides. From a landscape point of view, one of the remarkable features of the place is the amount of terracing that has been done. Many of the natural mounds and hollows have been squared and trimmed, the slopes made into terraces, and the ponds rounded. There are also formal elevated mounds from which good views of the gardens and lochs are to be seen. This kind of landscape art was more to the taste of a bygone time than it is to that of the present day. When newly done, its aspect must have been crude and hard, but the softening hand of time has done much to ameliorate its hard lines, and where an arboreal vegetation does not grow, a thick, well-kept turf covers it all. We must say of this phase of Castle Kennedy, what applies equally well to the formal garden at Drummond, and to the topiary work of Levens: one may not care to copy it, but it is in its way unique, and one would be sorry were it to be destroyed.

Here, as in so many Scottish gardens, the Conifers are the chief objects of interest. *Araucaria imbricata* is very fine, and produces cones regularly; there is a striking avenue of large specimens, one of which (it may not have been the largest) had a trunk 7 feet in girth. Equally striking to me, and less bizarre in its effect, was an avenue of *Cupressus macrocarpa*; one of the tallest was 60 feet high; another, branching low, was 9 feet 8 inches in girth at 2 feet from the ground. I saw many excellent specimens of various Silver Firs: *Abies Webbiana*, girthing 6 feet, with its naturally sown seedlings springing up around; *A. Nordmanniana*, also self-sown; *A. cephalonica*, 63 feet high and 9½ feet in girth; the rare Himalayan *A. Pindrow*, 60 feet high and 4 feet 5 inches in girth; the still rarer *A. religiosa*, from Mexico (the only specimen I saw in Scotland), 40 feet high; *Picea polita*, 20 feet high, well-furnished and well-formed; and *Cryptomeria japonica*, 50 feet high, with the unusual girth of 6 feet 3 inches.

The Holm Oak is not so fine individually here as it is at Kew, but a grove of forty of them gave one an idea of the "Ilex" woods of Southern Europe. I have already alluded to the *Rhododendrons*, but all the *Ericaceous* plants are remarkably well-grown. *Pieris floribunda* was 10 feet high, the scarce *P. mariana*, 7 feet high and through, *Kalmia angustifolia*, 6 feet high, *Cassandras*, 4 feet high, and many more equally notable.

TRADE MEMORANDUM.

RAT POISON.—It is stated that the use of a method discovered by Dr. Danyasz, of the Pasteur Institute, Paris, has proved an unqualified success. What we suppose is a similar preparation has been discovered in Copenhagen, and has been placed on the market under the name Ratin. Both preparations are said to be harmless, except to rats and mice, and free from objection. Rats are not only extremely destructive, but they are now known to be the carriers of plague, and perhaps other diseases. It is, it appears, not the rat itself but the flea which infests the rat which conveys the poison to the human being. We have no personal knowledge of either of these preparations, but we may add that particulars may be obtained from the Danyasz Company, 52, Leadenhall Street, and from the Ratin Company, 17, Gracechurch Street, London.

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

CAMELLIA FLOWERS FROM THE OPEN.—I am sending two Camellias plucked from a tree in the open in one of the shrubberies at Huntsham Court. I planted several Camellias from tubs last autumn, and the flower buds on the tree from which the blooms were gathered were then small, but notwithstanding all the frost we have had (20° were registered on February 8), they have developed. I also planted out a variegated single variety, but the buds half developed and then fell off. *W. H. Collett, Huntsham Court Gardens, Bampton, N. Devon.*

DAPHNE ODORA (INDICA).—In the south-west, where it is grown in the open, this is invariably known as *D. indica*. In some gardens it has attained a large size, a shrub in this neighbourhood being over 5 feet in height. It appears quite hardy and its deliciously-scented blossoms bear several degrees of frost without injury. Here, during the cold weather, we experienced ten degrees of frost on four nights, which killed several tender things, including *Salvia leucantha*, *Arctotis aureola*, *A. aspera arborescens*, *Solanum aviculare*, *Gazania longiscapa*, *Moræa* (*Iris*) *Robinsoniana*, *Myoporum lætum*, *Calceolaria Burbridgei* and *Psoralea pinnata*, but a week later I cut 30 bloom-clusters from my *Daphne*, which were quite fresh and uninjured. The perfume of these when they are brought into the house is delightful. The great drawback to this *Daphne* is that it is generally propagated by grafting, for grafted plants are seldom satisfactory. I have raised several from my bush by layering, and it can also be increased by cuttings of half-ripened shoots placed in sandy peat and kept in the propagating frame until rooted. *S. W. Fitzherbert, Kingswear, S. Devon.*

LENTEN ROSES (HELLEBORES).—A few years ago I had the pleasure of receiving some of Mr. Archer-Hind's varieties, following upon the receipt of a box of exquisite blooms. These plants have flowered with me several times, and they are very beautiful and vastly superior to the ordinary seedlings which can be purchased; in most cases better even than the named varieties which have been in cultivation for some time. The form is varied, and the colours present all the breadth of range mentioned by Mr. Fitzherbert. As he remarks, there are flowers from the purest white to the deepest maroon red, with beautifully spotted varieties besides. It is surprising that these flowers are not more commonly raised from seeds, for, although they take some little time to form plants capable of flowering, they are sufficiently compensating. Some of the strains of seed to be purchased are very good, but if the best results are desired recourse must be had to seed saved from one's own plants, care being taken to secure that they are gathered from the best plants alone. Another successful raiser of Lenten Rose seedlings whose flowers I have seen is Mr. Joseph Mallender, of Hodsock Priory Gardens, Workop. Mr. Mallender has some very finely-coloured flowers, and a box of blooms he sent me a few years ago included some of great beauty and of fine colouring. There is no doubt that some of Mr. Archer-Hind's and some of Mr. Mallender's are superior in their way to the majority of the named Continental varieties, sent out some years ago, beautiful as some of these are. *S. Arnott.*

CURE FOR BIG-BUD IN BLACK CURRANTS.—Through the medium of the *Gardeners' Chronicle* may I draw the attention of all growers of Black Currants to the importance of treating their trees with lime and sulphur wherever affected with the Black Currant Gall-mite? The first application, which should be dusted on, should be given at the end of this month, and should consist of one part of ground, unslaked lime to two parts of sulphur by weight. The second application should be put on a fortnight later, and consist of slightly less than one part of lime to two and a quarter parts of sulphur. A fortnight after this again dust the bushes with still less lime—say half a part to two and a half parts of sulphur. The dusting should be done in the early morning when the dew is on the bushes. This method of treatment has so far proved most effective, and I shall be glad to learn of the results from any who may use it this season. *Walter E. Collinge, The University Department of Economic Zoology, Birmingham March 14, 1907.*

NIOTIANA SANDERAE HYBRIDS.—For flowering at this season of the year these hybrids are valuable. I have a batch of plants in flower, and the colours are beautiful, especially those of crimson and purple shades. I have found it desirable not to pot them into large pots as the plants when growing too vigorously take up such a lot of room with their bottom foliage. I sowed the seed early in the autumn of last year, transplanted the seedlings into boxes and when they were large enough potted them into 3 and 4-inch pots. Many of the plants are 2 feet in height, and some are taller. They have a pleasing appearance in the greenhouse, rearing their heads of bloom above many of the other plants. *W. H. Collett, Huntsham Court Gardens, Bampton, N. Devon.*

NARCISSUS NOT FLOWERING (see p. 159).—In a note of mine on the above subject there is an editorially interpolated line which says: "The rudiments of the flower are formed in the spring, or not at all." This does not quite agree with my experience based on observation through many years. "Spring," of course, is a somewhat expansive term, but that season has long passed before it is possible to discover any signs of the new flower-bud. What happens is this. Up to the middle or end of May, and later in some varieties of *Narcissus*, the functions of the plants are directed to the putting forth of all the stored up energies of a past season, and long after the flower-stem has been removed there is a continuance of stem-growth from the bulb. Frequently a flowering stem after having been plucked from the plant at the ground level will extend to six inches or more, often to nine inches, the foliage meanwhile extending and developing. This growth in a moist season is long continued, and so long as this is the case the bulb is of an impressionable degree of softness. While this softness is observable—and it is evident in the more perpetual rooting varieties or sections till well into the month of June—I take it no bud-formation is possible. Later on, when the fully mature stage has been reached by the leaves, consolidation of the tissues of the bulb is set up anew, and, working on the principle that the house has first to be built and subsequently furnished, the germ of flowering, or the rudiments of the flower, would be the finale to the season's work. But only rarely in the month of July is the rudimentary bud discoverable in the bulb of a *Daffodil*, even when a high magnifying power is employed; and, judged by subsequent progress within the bulb while the latter is in the stage referred to as "dormant," it must be exceedingly minute in the month named. Later on in August, September and October, while the bulb remains in the dry state and out of the ground, the progress and development of the flower-bud within the bulb is very interesting. In the early part of the first-named month the rudimentary bud of pin point size or larger may be found, while in October the shapely bud, the true outline of the upper portion of the scape and the miniature green leaves are all revealed. To those who seek information on the point I know of nothing affording greater interest than the subject of bud development within the bulb. By selecting a few dozens of bulbs of equal size and cutting a few open each week to note the progress made, much valuable information may be obtained. The same bulbs may be used in two different ways, and by making one or more transverse cuts some useful hints may be gathered concerning the modes of increase, the progressive direction of bulb growth, and other things. *E. H. Jenkins, Hampton Hill.*

THE SEASONS AT VENTNOR.—I find the winter has killed many plants that have thriven out-of-doors here for years past. Very large trees of *Eucalyptus* are killed, also the Ivy-leaved *Pelargoniums* that cover the fronts of some of the houses are dead, the fine old bushes of white *Marguerites* are also killed. Last year at this time I found flowering out-of-doors *Cyclamen latifolium*, *Daphne indica rubra*, *Cytisus*, *Marguerites*, Ivy-leaved *Pelargoniums*, *Roses*, *Wallflowers*, *Polyanthus*, and *Violets* in variety. This year there is scarcely a flower, excepting *Primroses* and *Violets*. In a notable garden at St. Lawrence the winter had played havoc with hardy Cacti. *Cereus* and *Opuntias* are killed down to the ground, also one or two choice *Yuccas*. *Cyclamen latifolium* have suffered but not so severely, *Sparmannia africana* also is cut down, *Myrtles* have suffered somewhat. The gardener told me that for several days he registered 12° of frost day and night. There were few plants in

flower here such as *Anemones*, *Daffodils*, *Primroses*, *Winter Aconite*, and the beautiful little *Saxifraga Grisebachii*. Another garden I was in had all the variegated *Aloes* killed. What seemed to me rather a novelty were quantities of seedling *Laurustinus* and *Sweet Bays* coming up under the old trees, the gardener said he had never found them seed and come up in such quantities before. *T. P. Ventnor.*

WORKS OF RUSKIN.—May I call the attention of my fellow-gardeners to the recently published works of Ruskin at 6d. each? For years I have longed to be a possessor of some of these gems of literature, but the price has been too high; now, happily, that barrier is removed. "A Joy For Ever," "Unto This Last," and "The Two Paths," are published by George Allen, London. *H. Williams, Trevinca, Redruth.*

GARDEN NOMENCLATURE.—It is fortunate for those who grow fruits and vegetables, that generally the names of the many varieties found are short and easily pronounced. The worst examples perhaps in fruit are found amongst Pears, so many of which have long French appellations, but these, so far as possible, Britishers shorten, and yet they are clearly recognisable. In the matter of abbreviations, the market-people are doubtless great sinners, but the fact that with them, as with all who are growers, short, easily-pronounced appellations are most favoured, should weigh with raisers when they christen their products. Happily, even among the most difficult names in fruit or vegetables, none can at all compare with those quoted and so properly animadverted upon by Mr. Watson. The poor gardener has to bear many sins and sorrows, but it is unfair to him that he should, by outsiders, be credited with originating the tongue-splitting and barbarous names he so often, and it is to be feared, not always correctly, has to pronounce. With all classes of ordinary gardeners, and most certainly with the public, short crisp names are most in favour. Long terms, especially those that are of Latin or Greek derivation, are difficult to spell and write, and many a good thing has had to suffer because its long, difficult appellation created aversion. It is too often the case that an attempt is made to convey in a name some information as to the character of the product in question. That effort usually fails. Thus, in Peas we can well dispense with *Marrowfats* and *Prolifis*. *Gradus*, *Daisy*, or *Autocrat* are simple terms easily recollected, and are far better than other appellations of some three or four words. If such economy in naming could run through all sections of garden-products, there would be for them great gain and wider popularity. *A. D.*

THE EARLIEST BOOK ON CONIFERS.—*De Arboribus*, by P. B. Cenomani, was published in Paris in 1553, and is the earliest known work entirely devoted to coniferous trees. There are 64 pages, in which, amongst others, the genus *Pinus*, *Cedrus*, *Thuja* and *Cupressus* are included, and the illustrations are remarkably clear and truthful. It seems surprising at so early a date to find *Pinus Pinaster*, *P. taeda*, and *Cedrus major* (*Libani*) so carefully described and figured. *A. D. Webster.* [We find no reference to "Cenomani" in Pritzels. Probably the book intended is *Pierre Belon's De Arboribus Coniferis*, &c., Paris, 1553.—Ed.]

MUSA ENSETE.—For several years I have not grown this valuable species in tubs for sub-tropical groups, but have planted them in position in holes filled with rich soil. The plants so treated require less watering and produce larger leaves, which have a brighter midrib (this colour is perhaps its greatest attraction) than those plants which are plunged in tubs or large pots. After the leaves are spoilt by frosts, a few degrees do no harm, the leaves are cut off and the plants are lifted with a spade with 3 or 4 inches of soil around the stems and stored in a shed with the *Cannas*. Towards the end of March all the old soil is shaken off, the roots are trimmed, and the plants are put into as small pots as can be conveniently used, employing a compost of two parts of roughly broken loam and one part of leaf soil, with a good sprinkling of bone meal and sand, pressing the compost moderately firm. If rammed hard, small leaves will result. The plants are then placed in an early vinery and soon develop their leaves. In due course they are hardened and planted out, usually at the end of May. *A. C. Barilett.*

SOCIETIES.

ROYAL HORTICULTURAL.

MARCH 19.—Visitors to the Vincent Square Hall on Tuesday last had no reason to lament the absence of horticultural exhibits, for the building was filled with them. The South African Exhibition had been removed, bag and baggage, only a few hours previously, and the superintendent was at work in the hall in connection with that removal as late as one o'clock on Tuesday morning, but nothing of this work was apparent at the meeting on that day. The hall was delightfully gay with Orchids, Carnations, Hippeastrums, Cinerarias, forced flowering shrubs, and a most miscellaneous collection of plants and flowers. The ORCHID COMMITTEE recommended three Awards of Merit, and the FLORAL COMMITTEE four Awards of Merit. The FRUIT AND VEGETABLE COMMITTEE recommended a First-Class Certificate to a variety of Kale after trial at Wisley.

In the afternoon, 38 new Fellows were elected, and Mr. Barbour James delivered a lecture on "Horticulture in British Guiana."

Floral Committee.

Present: W. Marshall, Esq. (chairman); and Messrs. C. T. Drury, W. G. Baker, J. W. Barr, F. Page Roberts, T. W. Turner, G. Reuthe, C. Blick, J. E. McLeod, C. J. Salter, Jno. Jennings, Geo. Gordon, C. R. Fielder, Herbert J. Cutbush, James Douglas, W. Bain, Charles Dixon, Arthur Turner, Chas. E. Pearson, A. R. Goodwin, E. H. Jenkins, R. C. Notcutt, George Paul, M. J. James, R. Hooper Pearson, R. C. Reginald Nevill, and R. W. Wallace.

Messrs. W. CUTBUSH & SON, Highgate, London, N., displayed a magnificent group of forced flowering shrubs of the usual subjects, such as Azaleas, Magnolias, Spiræas, Wistarias, Lilacs, Laburnums, Ribes, Forsythia, &c. Some idea of the size of the exhibit may be formed when we state that it required eight large vans to convey the plants. The group was well arranged, and was enhanced with Ferns, Palms, Maples, &c., interspersed. As a separate exhibit, Messrs. CUTBUSH displayed a seasonable assortment of rock-garden plants, prominent among which was a specimen of *Stylophorum diphyllum* in flower. (Gold Medal.)

Messrs. R. & G. CUTHBERT, Southgate, London, N., also exhibited a fine array of forced shrubs, a feature of which were grand plants of Azaleas, and beautiful specimens of Lilacs. These, with Magnolias, Viburnum, Ericas, *Pyrus Malus floribunda*, and other showy subjects formed an exhibit of great beauty. (Silver-Gilt Flora Medal.)

Mr. L. R. RUSSELL, Richmond Nurseries, Richmond, Surrey, staged a group of forced shrubs, utilising a number of well-flowered Clematis, of large flowering varieties, as an edging to the group. (Bronze Flora Medal.)

Messrs. PAUL & SON, Old Nurseries, Cheshunt, Herts, staged a group of Lilacs in flower. The plants, which were home raised, were pretty examples, being compact and crowned with their beautiful racemes, mostly of double flowers. (Silver Banksian Medal.)

Messrs. JAMES VEITCH & SONS, Ltd., King's Road, Chelsea, showed interesting shrubs in flower, including the new *Jasminum primulinum*, *Clematis montana rubens*, a double variety of the white *Prunus sinensis*, *Cerasus serrulata*, greenhouse varieties of *Rhododendrons*, and some splendid Azaleas. On an adjoining table Messrs. VEITCH staged 120 seedling Hippeastrums of their excellent strain, and *Clivias*, Carnations, and other greenhouse plants. (Gold Medal.)

Messrs. H. CANNELL & SONS, Swanley, Kent, made a brilliant display with bunches of Zonal Pelargoniums of the finest varieties, and a batch of star and florists' Primulas of an excellent strain. The variety Reward of the stellata type has "pips" of an extraordinary size; the colour is white, with a beautiful yellow "eye." (Silver Flora Medal.)

Mr. R. GILL, Tremough Gardens, Penryn, Cornwall, displayed about 50 seedlings and 20 named varieties of *Rhododendrons*, all from the open ground. At the back were paintings of many species and hybrids of *Rhododendrons*, executed by Mrs. GILL, in natural colours. The

group also contained sprays of *Pieris* (*Andromeda*) *japonica*, *Erica codonodes*, &c., the freedom of flowering and luxuriance of growth being remarkable. (Bronze Flora Medal.)

Messrs. WM. PAUL & SONS, Waltham Cross, Herts, staged flowering Peaches, especially beautiful being the double white variety, the long growths of which were studded with the milk-white blossoms. Forsythias and Clematis *indivisa lobata* were intermingled with the Peaches. (Silver Banksian Medal.)

Mrs. WILLIAMS, Gerran, Cornwall (gr. Mr. E. Martin), staged vases of Violet Princess of Wales.

Mr. GEO. MOUNT, Canterbury, Kent, showed a splendid batch of the beautiful Rose Richmond, and other equally good blooms of Mrs. W. J. Grant, Frau Karl Druschki, and Mrs. R. G. Sharman Crawford. (Silver Banksian Medal.)

Messrs. T. ROCHFORD & SONS, Broxbourne, Herts, staged a batch of the handsome *Nephrolepis exaltata* *Todeaoides*, which formed the subject of our supplementary illustration in our issue for December 29. (Silver Flora Medal.)

Mr. H. BURNETT, St. Margaret's Nurseries, Forest Road, Guernsey, staged a group of winter-flowering Carnations, very similar to the exhibit which secured him the premier award at the recent exhibition of the Winter-Flowering Carnation Society. The beautiful variety Mrs. H. Burnett was much admired. (Silver Flora Medal.)

Mr. A. F. DUTTON, Iver, Bucks, had an exhibit of these popular flowers in most of the best varieties, for which a Silver Banksian Medal was awarded, and another excellent display of these Carnations was staged by Messrs. HUGH LOW & CO., Bush Hill Park, who also exhibited greenhouse flowering plants, including some Cyclamen of pretty shades of colours.

Lachenalia Nelsoni was shown very finely by Mr. BIECHOFFSHEIM, Warren House Gardens, Stanmore (gr. Mr. J. Doig). There were upwards of forty plants in 5-inch to 6-inch pots, some of the pots having ten strong flower spikes. The effect of the buttercup-yellow coloured flowers was much admired, and, viewed from a short distance, the inflorescences looked like miniature candelabra. (Bronze Banksian Medal.)

Clematises in such profusion as to suggest the coming of another Temple Show were shown by Mr. H. B. MAY, Dyson Road Nursery, Edmonton. These were nice plants in small pots, and were very freely flowered. The variety Marcel Moser, as usual, appeared very superior, but the white Mrs. Quilter, the mauve-coloured *Lawsoniana* of very large size, the deep-blue coloured Lord Nevill, and many others were included in the group. (Silver Banksian Medal.)

Mr. W. E. WALLACE, Eaton Bray Nurseries, Dunstable, had excellent bunches of tree Carnation flowers, and also blooms of several varieties of Roses, as the brilliant Richmond, which gained an Award of Merit at the last meeting, Frau Karl Druschki, &c. (Silver Flora Medal.)

Messrs. SUTTON & SONS, Reading, showed a large group of Cinerarias. On this occasion the plants were of the stellate-flowered type, and a particular strain in which the margins of the segments are rolled lengthways under themselves "revolute." The effect, therefore, is increased stellate, and the strain has been described as "Cactus flowered." The flowers are very pretty for decorative uses, and some may prefer them to those which produce larger flowers. In habit the plants are dwarf-growing like the florists' Cineraria rather than lax as the stellate type. The colours are varied and bright. (Silver Flora Medal.)

The old-fashioned *Thysacanthus rutilans*, a brilliant, winter-flowering greenhouse plant with pendulous racemes of scarlet, tubular flowers, was well shown by Lord ALDENHAM, Aldenham House, Elstree (gr. Mr. E. Beckett). The racemes were more than 3 feet in length. All the plants were arranged on stands 12 or 14 inches in height, and the plants themselves were more than 2 feet high; still the racemes reached the table, which was covered with white paper for effect. A selection of early-flowering shrubs was exhibited as sprays from the same garden, including *Berberis japonica*, *Prunus Davidiana* alba, *Daphne Mezereum* alba, *Lonicera fragrantissima*, also *Alnus*, *Corylus*, and *Salix* species, &c. (Silver Banksian Medal.)

E. A. HAMBRO, Esq., Hayes Place, Kent (gr. Mr. G. Grandfield), filled the whole of one side of a table with a collection of Alpine and other plants in pots. This collection included excellent specimens of many pretty and rare plants. *Daphne Blagayana*, for instance, was shown in a 10-inch or 12-inch pot, a good specimen in flower. Many of the Primulas, Hepaticas, Muscaris, &c., also bulbous plants were in bloom. *P. denticulata* alba was especially good. Some of the Saxifragas, Sempervivums, and others were shown, though not in bloom. The collection was studded and somewhat over-shadowed by half-a-dozen or so very large plants of *Rhododendron præcox* in flower. (Silver-Gilt Banksian Medal.)

Mr. G. REUTHE, Hardy Plant Nursery, Keaton, Kent, showed many interesting hardy flowers, Irises, Primulas, Crocuses, Anemones, Hepaticas, &c., and inflorescences of *Rhododendrons*. (Silver Banksian Medal.)

Messrs. BARR & SONS, King Street, Covent Garden, London, W., displayed a selection of seasonable hardy flowers, principally of Alpine and rock-garden species, among which were noticed such fine things as *Crocus biflorus* *Alexandrie*, *Anemone blanda scythica*, *Tulipa Korolkowii*, *Noccea* (*Iberis*) *stylosa*, *Juniperus hibernica compressa*, &c., and many Daffodils and other spring bulbous flowers.

THE CRAVEN NURSERY COMPANY, Clapham, Yorkshire, showed Alpine plants, including a beautiful collection of Saxifragas, among which we noticed magnificent specimens of *Saxifraga Burseriana*, the variety Gloria having extra large flowers. There were also grand plants of *S. Griesbachii*, *S. Boydii* alba, *S. Frederici*, *Augusti vera*, &c.

Exhibits of Alpine and rock-garden plants were also displayed by the Misses HOPKINS, Barming, near Maidstone, Kent; Messrs. JOHN PEED & SONS, Forest Hill; Messrs. T. S. WARE & SONS, LTD., Feltham (Silver Banksian Medal); and Messrs. J. CHEAL & SONS, Crawley, Sussex.

A new species of *Thibaudia* was shown by J. T. BENNETT-POE, Esq., Holmwood, Cheshunt, to which we shall refer on a future occasion.

AWARDS OF MERIT.

Magnolia Soulangeana nigra.—This is the deepest-coloured form of this well-known variety. The flowers are of an exceedingly rich brownish-purple shade. In other respects the variety is like the type, especially in the form of the flowers which are well coloured in the interior, although the shade is much deeper on the exterior. Shown by Messrs. R. & G. CUTHBERT.

Rhododendron "Duke of Cornwall."—This is one of the most brilliant-coloured *Rhododendrons*, being of bright-red colour, which lights up grandly under the rays of the sun. It was raised as a cross from a variety of *R. arboreum*, and the species *R. barbatum*. The leaves are 10 inches long, 2 inches across at the widest, and almost smooth on the under surface. The variety is described as being as hardy as *R. Pink Pearl*, *R. Kewense* X, &c. Shown by Mr. R. GILL, Tremough, Devon.

Rhododendron Kewense X.—This is a well-known and beautiful hybrid raised at Kew from a cross between *R. Griffithianum* and *R. Hookeri*. It was illustrated in these pages May 14, 1898. This hybrid is usually described as pink-flowered, but occasionally plants are perfectly white-flowered, as was the specimen exhibited by Messrs. PAUL & SONS, on Tuesday last.

Saxifraga Burseriana "Gloria."—This is the best form of *S. Burseriana* we have seen, the flowers appearing larger and stronger than those of *S. Burseriana major*. Shown by THE CRAVEN NURSERY COMPANY.

Narcissus Committee.

The committee met on this occasion, but they had little to do. The principal exhibit that came before their notice was a very large group of forced Narcissi and Tulips shown by Messrs. CUTBUSH & SONS, Highgate, and for which a Silver-Gilt Flora Medal was awarded. Messrs. BARR & SONS, King Street, Covent Garden, also exhibited a fine group of *Nar. issi*. Mr. BAYLOR HARTLAND, Ard Cairn, Co. Cork, Ireland, showed one or two seedling Narcissi, and Sir EDMUND LODER, Bart., Leonardslee, Sussex (gr. Mr. W. A. Cook), sent a natural hybrid of *N. cyclamineus* X *N. minimus*.

Orchid Committee.

Present: J. Gurney Fowler, Esq. (in the chair); and Messrs. Jas. O'Brien (hon. sec.), Harry J. Veitch, De B. Crawshaw, J. Wilson Potter, H. Little, W. Boxall, G. F. Moore, F. M. Ogilvie, T. W. Bond, A. A. McBean, F. Sander, J. Charlesworth, H. T. Pitt, Fred. J. Hanbury, W. Cobb, R. G. Thwaites, H. A. Tracy, W. H. Young, H. G. Alexander, F. J. Thorne, H. Ballantine, W. A. Bilney, W. Bolton, and W. P. Bound.

Messrs. CHARLESWORTH & Co., Heaton, Bradford, were awarded a Silver-Gilt Flora Medal for a very fine exhibit that was rich in good things. The leading subjects were grouped, in the centre being forms of *Lælio-Cattleya* Myra and similar hybrids. A batch of the fine Heaton forms of *Odontoglossum Rolfeae*, a group of good *O. crispum*, another of various hybrid *Odontoglossums*, including *O. Ossulstoni*, *O. Othello*, *O. Lawrenceanum*, *O. ardentissimum*, *O. Phoebe*, &c.; a selection of brightly-coloured *Cattleya* Enid, and *C. Empress Frederick*, and several rich scarlet *Sophro-Lælia* Psyche. Various interesting species and natural hybrids were also seen.

Messrs. JAS. VEITCH & SONS, Royal Exotic Nursery, King's Road, Chelsea, secured a Silver Flora Medal for an extensive and showy group composed principally of very finely-flowered *Dendrobium* Wardianum, *D. crassinode* of the best type, *D. nobile* in variety, a selection of *Odontoglossum crispum*, and other good species. The front was of the fine yellow *Oncidium concolor*, behind which was a selection of the new *Cypripedium* Countess of Carnarvon, &c.

Messrs. JAS. CYPHER & SONS, Cheltenham, were awarded a Silver Flora Medal for a group in which their fine *Dendrobiums* were well represented; also *Odontoglossum crispum* and *O. Pescatorei*, both of excellent quality. It contained also good forms of *Lycaste Skinneri*, including finely-flowered plants of the pure white form. Among the *Cattleyas* were some excellent specimens of *C. Schroderae*, one having very large parts, the broad petals and the lips being both finely crimped; a good *C. calum-mata*, *C. Trianae*, &c. Of *Cypripediums*, we noted the massive *C. Beekmanni* and *C. Tixalense*.

Messrs. SANDER & SONS, St. Albans, were awarded a Silver Flora Medal for an effective group, in which the varieties of *Cattleya Trianae* were prominent. The best were *C. T. E. Cooper*, a good white flower, with a delicate lavender tint, and broad labellum, the front of which was of a peculiar shade of violet; a good example of *C. T. Backhousiana*, and one of the new *C. T. plumosa*, with crimson tips to the petals; similar to *Backhousiana*, but with a darker, purplish-crimson lip. Among hybrids, the richly-coloured *Lælio-Cattleya blatchleyensis ardens* was the best, its intense ruby-crimson lip, veined with claret colour, being very beautiful.

Messrs. ARMSTRONG & BROWN, Tunbridge Wells, were awarded a Silver Flora Medal for a neat group of finely-flowered *Dendrobiums*, *Cypripediums*, &c., specially good being *Zygopetalum Gottianum*, one of the finest hybrid *Zygopetalums*.

R. I. MEASURES, Esq., Cambridge Lodge, Camberwell (gr. Mr. Smith), showed a selection of hybrid *Cypripediums*, two plants of *Cymbidium Wiganianum*, a good specimen of *Platyclinis glumacea*, &c.

C. J. LUCAS, Esq., Warnham Court (gr. Mr. Duncan), sent *Lælio-Cattleya Amelia* (*L. harpophylla* × *C. Percivaliana*), *L.-C. Adelina* (*L. cinnabarina* × *C. Percivaliana*), and *Cypripedium Pauline*.

FRANCIS WELLESLEY, Esq., Westfield, Woking (gr. Mr. Hopkins), showed *Lælio-Cattleya* Mrs. R. A. H. Mitchell (*C. Warszewiczii* × *L.-C. Martinetii*), a showy hybrid, with rose-purple tinted sepals and petals, and having a fine purple lip veined with claret colour, merging to rose towards the margin.

JEREMIAH COLMAN, Esq., Gatton Park (gr. Mr. W. P. Bound), again showed the large and beautiful *Dendrobium Othello* "Colossus."

MONSIEUR MERTENS, Mont St. Amand, Ghent, showed a selection of hybrid *Odontoglossums*.

MONSIEUR FLORENT CLAES, Etterbeek, Brussels, showed *Odontoglossum crispum* Fr. Claes, a very handsomely-blotched form of great

merit. The sepals and petals were white, tinged with rose, the reverse side with deep purple, which showed through to the face in the parts surrounding the large, claret-coloured blotches. Also *O. crispum* Rita Claes, a pretty flower near to the famous *O. c. Lady Jane*; and *Cattleya Trianae* Queen Wilhelmina, another good flower.

Messrs. HUGH LOW & Co. staged a group of *Dendrobiums*, *Cypripediums*, &c.

Major G. L. HOLFORD, C.I.E., C.V.O., Westonbirt, Tetbury (gr. Mr. H. G. Alexander), exhibited *Lælio-Cattleya* × *Olivia* (*L. Jongheana* × *C. Schroderae*) of the size and colour of the best *C. Schroderae*, but thicker in substance. The same exhibitor also displayed the very fine *Odontoglossum crispum* Rosemary (see Awards).

Mr. H. A. TRACY, Twickenham, showed *Odontoglossum loochristense* "Edith Wynne," a very large and finely-formed flower of a clear yellow colour, heavily blotched with chestnut red.

F. G. GLEDSTANES, Berry Hill, Taplow (gr. Mr. Milsom), sent heavily flowered, cut pseudo-bulbs of *Dendrobium nobile* and *D. Wardianum giganteum*.

G. F. MOORE, Esq., Chardwar, Bourton-on-the-Water (gr. Mr. Page), exhibited *Cypripedium* Chas. Lucas (*Beekmanni* × *Swinburnei magnificum*) and *C. Mrs. Fred. Hardy*.

DE B. CRAWSHAY, Esq., Rosefield, Sevenoaks (gr. Mr. Stables), showed three fine plants of the superb *Odontoglossum triumphans* Lionel Crawshaw.

AWARDS.

AWARDS OF MERIT.

Odontoglossum crispum Rosemary.—A magnificent variety of the typical *O. crispum*, having white flowers slightly tinged with rose. The sepals and petals are almost equally broad, and they measure nearly 5 inches across. The finely-grown specimen bore a spike of nine flowers. From Major G. L. HOLFORD, C.I.E., C.V.O. (gr. Mr. H. G. Alexander).

Odontoglossum crispum Lily Bourdas.—A very beautiful example of the blotched *O. crispum*. The flowers are of good form, and are white, with purple at the back, which shows through to the face of the flower. Each segment bears a large cluster of reddish-claret blotches. The lip is white with brown blotches in front of the yellow disc. Shown by H. S. GOODSON, Esq., Fairlawn, West Hill, Putney (gr. Mr. G. E. Day).

Cymbidium Colmana, *Edenside* variety (*eburneum* × *eburneo-Lowianum*), from Mr. JAS. DOUGLAS, Edenside, Great Bookham. In the original form shown by Jeremiah Colman, Esq., there was a slight colour on the lip. The present form adheres closely to the waxlike texture and ivory-white colour of *C. eburneum*.

CULTURAL COMMENDATION.

To Mr. Warrington (gr. to Miss M. E. RUSHTON, Monks Manor, Lincoln) for a magnificent specimen of *Cypripedium Rothschildianum*, with eight spikes, bearing altogether twenty-seven flowers.

CHANGE OF NAME.

Odontoglossum Lady Howick.—The plant which received an Award of Merit under the name of *O. mirum* Lady Howick had its name changed to *O. Lady Howick* (parentage unrecorded), there being a doubt about the former record.

Fruit and Vegetable Committee.

Present: A. H. Pearson, Esq. (in the chair); and Messrs. Alex. Dean, Ed. Beckett, H. Parr, Geo. Kelf, Jno. Lyne, H. Markham, J. Davis, Geo. Reynolds, W. H. Divers, Chas. Foster, J. Willard, P.-C. M. Veitch, H. Somers Rivers, James Vert, and James Gibson.

A very fine sample, contained in several baskets, of Ailsa Craig Onion was shown by MARK FIRTH, Esq., Wiston Hall, Leicester (gr. Mr. F. J. Clark). (Silver Knightian Medal.)

Messrs. T. RIVERS & SONS, Sawbridge-worth, Herts, displayed ripe fruits of Oranges, gathered from the pot trees exhibited at a recent meeting of the Society. Included were other fruits of the genus *Citrus*—Lemons, Citrons, Shaddock, &c. (Silver Banksian Medal.)

FIRST-CLASS CERTIFICATE.

Kale Chow de Russie.—This variety was granted this award—after trial at Wisley—and

on the recommendation of the sub-committee, whose visit and a note of the trial is described on p. 192. It is a very large headed Kale, and has thick side growths, the foliage being very deeply cut. The centre forms a head of very tender leaves, with very little waste. Sent by Messrs. J. CARTER & SONS, High Holborn.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

MARCH 7.—Committee present: E. Ashworth, Esq. (chairman); and Messrs. R. Ashworth, Thorp, Ward, Williamson, Sander, Keeling, Cypher, Walmsley, Shill, Warburton, Leemann, Parker, P. Smith, P. Weathers (Hon. Sec.).

There was an excellent exhibition, and the meeting-room presented a very gay appearance.

Mr. Z. A. WARD, Northenden, exhibiting for the first time at Manchester, staged a charming collection of well-grown plants of choice and interesting varieties of *Odontoglossums*. (Silver-Gilt Medal.)

Messrs. SANDER & SONS, St. Albans, staged a group of plants, in which was a distinct strain of *Cattleya Trianae*, each variety being of a pale colour bordering on the true albino forms. (Silver Medal.)

Messrs. CYPHER & SONS, Cheltenham, staged a group of miscellaneous plants. (Silver Medal.)

W. THOMPSON, Esq., Stone, obtained a Silver Medal for a group of plants, principally *Odontoglossums*.

A. WARBURTON, Esq., Haslingden, also gained a Silver Medal for a choice and varied exhibit.

First-Class Certificates were awarded to *Odontoglossum* × *Wardii*, *O. polyanthum* × *O. Harryanum*, all shown by Z. A. WARD; *Lælio* × *Cattleya* × *Dominiana* var. *magnifica*, shown by Messrs. CYPHER & SONS; and *Odontoglossum crispum* var. *Mossiae*, exhibited by J. S. Moss, Esq.

Awards of Merit were granted to *Odontoglossum* × *amabile* var. "King Edward VII.," *O.* × *Waltonense*, Ashland's var., *O. crispum* var. *Dido*, these three from R. ASHWORTH, Esq.; *O.* × *Crawshayanum* superbum, shown by W. THOMPSON, Esq.; *O.* × *Phoebe*, Ward's variety, *O.* × *Elaine*, *O.* × *Rolfæ*, Ward's variety, the three last-named from Z. A. WARD, Esq.; *Vanda Watsoni* (new species) and *Cypripedium* × *Hunterii*, both exhibited by Messrs. SANDER & SONS; *C.* × "Madeline" and *Odontoglossum* × *Adrianæ*, Ashworth's var., both presented by R. ASHWORTH, Esq.; *Odontoglossum* Cooksonianum, *O.* × *loochristense*, "Empress Frederick," *O.* × *Lambeauium*, Vine House variety, and *Cattleya Trianae*, "The Don," the last-named from A. WARBURTON, Esq.

A Botanical Certificate was given to *Sarcophilus Fitzgeraldii* from the collection of G. W. JESSOP, Esq. P. W.

CATALOGUES RECEIVED.

R. H. BATH, Ltd., Floral Farms, Wisbech—Plants, and Seeds.

KENT & BRYDON, Darlington—Firm Seeds.

COOPER, TABER & Co., 90 & 92, Southwark Street, London, S.E.—Seeds (wholesale).

RANSOMES, SIMS & JEFFERIES, LTD., Orwell Works, Ipswich—Lawn Mowers.

WAKEMLEY BROS. & Co., LTD., Honduras Wharf, Bankside, London, S.E.—Hop Manure.

CLIBRANS, Altrincham and Manchester—Dahlia.

H. ELLIOTT, Hassocks, Sussex—Carnations, Chrysanthemums, Roses, &c.

HARRISON & SONS, Seed Growers, Leicester—Firm seeds.

A. W. P. PIKE, Dianthus Villa, Llanishen, Cardiff—Carnations and Picotees.

BARR & SONS, 11, 12 & 13, King Street, Covent Garden, London—Hardy Perennials, Alpines, Aquatics, &c.

Messrs. KIPPING, Hutton, Essex—Hardy Perennials and Alpines.

FOREIGN.

SOUPERT & NOTTING, Luxemburg (Grand Duchy)—Roses.

Dr. RENATO ROVELLI (Fratelli Rovelli), Pallanza, Lago Maggiore.—This list includes some choice plants for the cool temperate house and sub-tropical regions. Shrubs, trees, evergreens and rare Conifers are specially noted.

ANT. ROOZEN & SON, Overveen, near Haarlem, Holland—Bulbs and Seeds.

CLAUDE FERLAT, 126, Rue d'Heyrieux, Monplaisir, Lyon, Rhône—A general catalogue, and with special reference to Carnations and Roses.

VILMORIN, ANDRIEU ET CRE., 4, Quai de la Mégisserie, Paris—List of Novelties, Vegetable, Fruit and Flower Seeds and Plants, and Gladiolus corms.

L. BOEHMER & Co., 5 & 28, Bluff, Yokohama, Japan—Lilium longiflorum and its varieties.

GARDENING APPOINTMENTS.

- Mr. G. J. GOODALL, for the last 15 years Gardener to the late G. H. MORRELL, Esq., Strealey House, near Reading, as Gardener to THOS. B. BAUGGS, Esq., Holton Park, near Oxford. (The ls. has been put into R.G.O.F. Box.)
- Mr. E. YOUNG, for the last 4 years Gardener and Orchid Grower to F. A. BROWNE, Esq., Norcott, Hampton Wick, as Gardener to H. S. TOWGOOD, Esq., Riversfield, St. Neots, Hunts.
- Mr. HERBERT STOWE, as Gardener to V. DE C. HUGHES, Esq., Galltown, Kilcullen, Co. Kildare.
- Mr. RICHARD HOWELLS, for nine years Gardener at Stallington Hall, as Head Gardener to C. B. TOLLER, Esq., Aston Bank, Hawarden, Chester.
- Mr. ALBERT PRATT, for the past six years Gardener to J. DEWRANCE, Esq., Cranmore Place, Chislehurst, Kent, as Gardener to C. BAYER, Esq., Tewkesbury Lodge, Forest Hill, London, S.E.
- Mr. E. BUNBURY, for 23 years Gardener at Arundel Castle, Sussex, is retiring from Arundel in order to take charge of the gardens at Beech Hill, Sheffield.
- Mr. WALTER H. ROGERS, late Foreman of Banstead Wood, Surrey, as Gardener to T. M. FRANKLIN, Esq., St. Hilary, Cowbridge, South Wales.
- Mr. D. McLACHLAN, lately Gardener at The Dolphin Hotel, Cleethorpes, Lincolnshire, as Gardener to Miss SURTRES, Hainsterley Hall, Rowlands-Gill, Newcastle-on-Tyne.
- Mr. R. BROWN, for the past five years Foreman at Stanwick Park, Darlington, as Gardener to General CALTHORPE, Perry Hall, Birmingham.
- Mr. J. H. JONES, late Gardener to BATEMAN L. ROSE, Esq., Torry Hill, Sittingbourne, Kent, as Gardener to ARTHUR WHITAKER, Esq., Chiddington Castle, Eden Bridge, Kent.
- Mr. A. PARRY, late of The Isle of Dogs, Three Ashes, Ross, Herefordshire, as Gardener to the Lady ALICE W. FITZWILLIAM, Eastcliff, Bemburgh, I.W.
- Mr. WM. PURVER, as Gardener to The Right Hon. Sir ROBERT ROMER, Hermead Bury, Buntingford, Herts.
- Mr. F. G. OCLEX, for the past two years Gardener to Sir R. BLOIS, Bart., Cockfield Hall, Yoxford, as Gardener to P. W. COBBOLE, Esq., Kesgrave Hall, Ipswich.
- Mr. MATTHEW NICHOLLS, for the past 44 years Gardener at Alice Holt, near Farnham, Surrey, as Head Gardener to Sir M. E. COLLET, Bart., St. Clere, Kemsing, Sevenoaks, Kent.
- Mr. MAURICE JONES, late of Hullbank Hall Gardens, near Hull, as Gardener to A. HARRISON SMITH, Esq., Carlton Hall, near Worksop, Notts.
- Mr. JAMES P. REID, for the past 24 years Foreman at Newberries, Radlett, Herts, as Gardener to HATFIELD HARTER, Esq., Cranfield Court, Woburn Sands, Beds.
- Mr. WM. H. TISSINGTON has succeeded his late father as Gardener to Mrs. G. LOCKER-LAMSON, Barborough Hall, Chesterfield, Derby.
- Mr. ERNEST BIGGS, for the past three years Foreman at Garnstone Castle, as Gardener to ISAAC MARSHALL, Esq., Sarnesfield Court, near Woolley, R.S.O. (The two shillings has been placed in R.G.O.F. box.)

THE WEATHER.

THE WEATHER IN WEST HERTS.

Week ending March 20.

Continued high winds. This was the warmest week as yet experienced here this year. There have been warmer days, but on no night previously has the thermometer exposed on the lawn indicated so high a temperature as it did on the night of the 16th, when the minimum reading was 49°. The ground has also become warm, being at the present time 2° warmer at 2 feet deep, and 8° warmer at 1 foot deep. It is a seasonable. Rain has fallen on all but two of the last 15 days, but to the aggregate depth of only 1½ inch. In fact, so evenly was the rainfall distributed, that on none of those days did the amount deposited rise to even a quarter of an inch. Some rainwater has come each day through both the percolation gauges, but the amounts have been small, and gradually diminishing. Although for two consecutive days the sun shone for altogether less than half an hour, yet the mean daily record for the whole week amounted to 54 hours, which is two hours a day in excess of the March average. The most noteworthy feature was, however, the persistently high winds. The roughest period was between 2 p.m. on the 19th and 6 a.m. on the 20th, when the average velocity of the wind for those 16 hours amounted to 21 miles. To show how uniform was the rate of movement it may be stated that in the windiest of those hours the mean velocity was only 23 miles—direction west. The average amount of moisture in the air at 8 p.m. fell short of a seasonable quantity for that hour by 6 per cent. E. M., Berkhamsted, March 20, 1907.

Obituary.

J. COCHRANE.—We regret to record the sudden death on Monday last of Mr. William J. Cochrane, for some years past manager of Messrs. Hurst & Son's flower-seed department at Houndsditch.

ROBERT WARRINGTON, F.R.S.—The death of this distinguished agricultural chemist is announced to have taken place on March 20, at High Bank, Harpenden.

ENQUIRIES AND REPLIES.

MOLES.—Is it possible to keep moles out of a garden by sinking wire (netting) around it, say 8 feet deep? T. Kensington.

ANSWERS TO CORRESPONDENTS.

* * * The Editor will be glad to receive, for consideration, large photographs of horticultural subjects, suitable for forming Supplementary Illustrations to this Journal.

ALLOTMENT GARDEN: C. B. W. You might obtain the *Calendar of Garden Operations* from our publishing department, price 7½d. post free.

AZALEA WITH GALLS: Z. G. The swellings are galls caused by a fungus—*Exobasidium Rhododendri*. You can do nothing now but pluck off the affected leaves and burn them. Spray them with or dip them in some fungicide, such as Bordeaux mixture or Condy's Fluid.

BOOKS: F. B. *Orchids: their Culture and Management*, by W. Watson, price 25s. 6d. *The Orchid Grower's Manual*, by B. S. Williams, price 16s. 7d. *The Amateur Orchid Cultivator's Guide Book*, by H. A. Burberry, price 5s. 4d. *The Culture of Greenhouse Orchids*, by Frederick Boyle, price 8s. 4d. *The Book of Orchids*, by W. H. White, price 2s. 9d. Any of these works can be obtained from our publishing department free by post for the prices named.

CORYLINE ROOTS: X. The union was only superficial. We laid your specimens in a pan of water, with the result that the roots became separate after a short time without being touched.

CYANIDISING PLANT-HOUSES: D. W. B. We should not think 1oz. of sodium cyanide (130 per cent.) per 1,000 cubic feet of space would injure the most delicate plant. Several correspondents who have written in our pages on the subject recommend 2oz., so we are not certain if 1oz. would be effectual. In our issue for March 3, 1906, is a report of a lecture given by Mr. H. Westcott before the members of the Sevenoaks Gardeners' Society. In it he states: "For cold houses I have found a remarkably small dose sufficient—namely, 2oz. of sodium cyanide to every 1,000 cubic feet of space." You should look up this number of the *Chronicle*, for the lecture is full of information on the subject, but in any case exercise the greatest care, as you will be dealing with a most virulent poison.

DAFFODILS: P. G. There will be a special exhibition of Narcissi in the R.H.S. Hall, Vincent Square, Westminster, on April 16. The middle of April would be a very good time at which to visit Kew Gardens for the purpose of seeing the hardy bulbs in flower.

INSECTS: C. E. The common cockroach. Place some of Steiner's beetle paste about the house on pieces of broken flower pot; as this is a very poisonous substance, it should be placed out of children's reach. Cockroaches can be trapped in common garden mats placed on the hot-water pipes.

LEAF TO NAME: W. H., Blackburn. should send a better specimen properly packed.

NAMES OF FLOWERS, FRUITS AND PLANTS.—We are anxious to oblige correspondents as far as we consistently can, but they must bear in mind that it is no part of our duty to our subscribers to name either flowers or fruits. Such work entails considerable outlay, both of time and money, and cannot be allowed to disorganise the preparations for the weekly issue, or to encroach upon time required for the conduct of the paper. Correspondents should never send more than six plants or fruits at one time: they should be very careful to pack and label them properly, to give every information as to the county the fruits are grown in, and to send ripe, or nearly ripe, specimens which show the character of the variety. By neglecting these precautions correspondents add greatly to our labour, and run the risk of delay and incorrect determinations. Correspondents not answered in one issue are requested to be so good as to consult the following numbers. **FRUITS: D. Henry.** Flower of Kent.

PLANTS: A. S. 1, *Picea orientalis*; 2, *Cupressus Lawsoniana*; 3, *C. Lawsoniana* var.; 4, *Juniperus sinensis*; 5, *Thuya occidentalis*; 6, probably *Juniperus sinensis*.—**F. S.** 1, *Polystichum lobatum*; 2, *P. lonchitis*; 3, *Cupressus sempervirens* var., or perhaps *C. Benthami*; 4, perhaps *Cupressus Knightiana*. In the absence of cones it is impossible to name even such good specimens as yours with certainty.—**T. D. A.** 1, *Sedum spurium*; 2, *S.*

sexangulare; 3, *S. dasyphyllum*; 4, *S. acre*; 5, *Eupatorium vernale*.—**S. Newbiggin.** *Narcissus incomparabilis sulphureus plenus*, commonly called Codlins and Cream.—**W. B.** *Odontoglossum cirrosum*.—**A. R.** 1, *Odontoglossum retusum*; 2, *Sophranitis cernua*; 3, *Ada aurantiaca*; 4, *Epidendrum Stamfordianum*.—**A. I.** *Chlorophyllum Sternbergianum*.—**E. B.** 1, *Sedum reflexum*; 2, *Euphorbia myrsinites*; 3, *Populus* male flower, probably *P. canadensis*; 4, *Arrhenatherum bulbosum*; 5, *Helleborus orientalis* var. *roseus*; 6, *H. orientalis*.—**A. J. C.** 1, *Cupressus Lawsoniana*; 2, a Cedar, perhaps *C. Libani*; 3, *Cryptomeria japonica*; 4, *Pinus excelsa*; 5, *Retinospora plumosa*; 6, *Cornus mas*.—**W. W.** Chickweed, *Stellaria media*.—**J. R. F.** 1, *Cupressus pisifera* var. *filifera*, commonly called *Retinospora filifera*; 2, *Cephalotaxus drupacea*, fastigate variety; *Abies Pinsapo*; 4, *Thuya orientalis Vervaneana*; 5, *Juniperus virginiana* var. *Schottii*; 6, *Cupressus Lawsoniana* var.; 7, a Cedar, perhaps *C. atlantica*.—**R. J. F.** *Abutilon megapotamicum*, variegated form.

PALM LEAVES DISEASED: P. M. G. The leaves are attacked by a fungus, *Graphiola Phoenixis*. Cut out and burn the worst leaves and spray the remaining ones with a fungicide, such as Bordeaux mixture or Condy's Fluid (permanganate of potash).

PEACH SHOOTS: W. O. The injury is brown rot caused by *Sclerotinia fructigena*. Cut out all diseased branches, and when the trees are resting next winter, syringe them thoroughly twice, at intervals of a month, with a solution of sulphate of copper, 1lb. dissolved in 25 gallons of water. This wash kills the foliage, and must therefore be used before the buds begin to swell.

PONPON DAHLIAS SUITABLE FOR THE GARDEN: A. C. The following 12 varieties with their colours are especially recommended by the National Dahlia Society for their general excellence as garden varieties, and especially for their freedom of flowering:—*Nerissa*, rose, tinted silver; *Daisy*, amber and salmon; *Tommy Keith*, cardinal, tipped white; *Bacchus*, crimson-scarlet; *Phoebe*, golden-orange; *Jessica*, amber, edged red; *Buttercup*, golden-yellow; *Douglas*, maroon, shaded crimson; *Darkest of All*, nearly black; *Thalia*, rose-pink, with white eye; *Guiding Star*, pure white; *Little Bugler*, rose purple.

RAMBLING ROSES: Rambler. Contrary to our rules, you have not furnished us with your name and address, consequently we do not know in what district the *Roses* are cultivated. It may safely be said, however, that in localities at all comparable to the neighbourhood of London in respect to its climatic conditions, *Rambler Roses* are not usually in flower out of doors in the first week of June. The pot plants may be allowed to grow out of doors until some time in May, removing them into a warm house sufficiently early to expedite their flowering. The time for removal indoors cannot be accurately stated now; it will depend upon the forwardness of the season. A good white or cream coloured variety is *Felicité et Perpetue*. *Trier* is another good white variety.

STRAWBERRIES FAILING TO SET: G. W. We suspect the failure is due to the pollen being shed before the stigmas have become receptive. If you have other batches of Strawberries in flower, pollinate the flowers of the one batch with those of the other by means of a rabbit's tail tied to a stick. It is advisable when forcing Strawberries to have a few plants of some free-setting variety in the house, intermingled with the main batch of plants. If the pollen ripens before the stigmas, a condition called by botanists "protandry," the flower is prevented from self-fertilisation. The Strawberry in its natural state has at least functionally unisexual flowers.

TULIP DISEASED: J. E. W. The failure is due to a fungoid disease caused by a species of *Botrytis*. Your best plan will be to burn the plants that were forced, to prevent the disease from spreading. Any bulbs in the beds should receive a dusting of slaked lime. See note on page 168.

THE HEIGHTS, WITLEY.

THE property and country house of Colonel Lord Edward Pelham Clinton, K.C.B., and family. The house, as its name implies, stands on a high eminence in Surrey, and commands extensive and magnificent views of the Sussex Downs in the distance, and especially of two historical elevations, the "Chanctonbury Ring" and the "Ancient Camp Ring," and of much of the rich pasture and woodland scenery lying between. Although the area of the garden is but small (eight acres), the pleasure derived from this diversified and beautiful landscape is as much his lordship's possession as if it formed a portion of his small domain, and adds immensely to the beauty and interest of the position. This part of Surrey, by its homely scenes and quiet beauty, has attracted to itself, as residents, artists and men and women of letters of world-wide renown. It is not far from Tennyson's old home; Birket Foster, Robertson, Arthur Melville, Helen Allingham live, or have lived, hereabouts; and the residence under notice will be associated for all time with the name of George Eliot, who lived here from 1876 to 1880.

The house has been considerably enlarged and improved by his lordship. Its architectural appearance, with its Virginian Creeper-clad walls, appeals to one's sense of homeliness and comfort more than to any sense of grandeur. The same may be truly said of the garden. The mature growth of its trees, its immunity from objects which might offend the eye are complete—not a building nor a jarring feature is to be seen—nothing but trees, pasture land, and hills: a pleasanter or a more restful outlook it would be difficult to conceive.

The garden was laid out about 50 years ago by Mr. Paxton (afterwards Sir Joseph), and presents many features of interest. The boundary plantation here is one of the best examples I have seen of the possibility of shutting out from view undesirable objects in a difficult position by intelligent planting. As already mentioned, the gardens are of limited extent, and are bounded on one side by a public road leading from Godalming to Haslemere, on another by the London and South Western Railway and Witley Station, on another by a public lane, and on another by a private residence. Yet so cleverly has the work of planting been thought out and executed with the object of securing privacy that, once inside the grounds, this object is as effectively secured as if the garden were in the heart of Sherwood Forest, near Clumber, the ancestral home of his lordship's family. This miniature wood not only ensures this useful purpose, but it forms a glorious setting or framework to the whole garden. The side of it facing the garden is planted with choice Conifers, hardy flowering trees and shrubs, forming a delightful bank of evergreen and other trees. The plantation is formed of Scotch and other Pines, with here and there introduced a few Oaks, Spanish Chestnuts, Beech, Limes, Robinias, &c. These have now attained to considerable height, and form conspicuous and handsome objects towering, as some of them do, high above the dwarf growth of the Pines. The wood is intersected with many informal, winding paths, the margins of which teem in spring with Daffodils and other bulbous and early spring flowers. In summer it affords refreshing shade, and in autumn the brilliant colours of the deciduous trees, in contrast with the pleasant green of the Scotch Pines, forms a picture which is most pleasant to look upon, and the shelter afforded to the house and garden by the trees is invaluable. There is one other instance here of successful screening by planting that I will mention. The stables are too near the house, forming an objectionable feature on the carriage side entrance. The space at disposal was too contracted to plant them out, and to build a wall was out of the question, so it was determined to erect a high, wooden screen made of small, diamond-shaped lattice work, against which Irish Ivy was planted. This is now densely covered, and an object of pleasure to look upon, as well as having effectively secured the object in view.

The pleasure ground, although of limited extent, is replete with objects of interest and beauty. The lawn in front is on an acutely sloping ground, and the front of the house is supported by a terrace of moderate dimensions, its bank being planted with St. John's

Wort instead of grass. From this terrace and the drawing-room windows opening on to it a glorious view is obtained of the distant scenery mentioned before, as well as a delightful bird's-eye view of the whole of the grounds. On the right, opposite to Mrs. Farnham's boudoir, is a fine group of old Scots Pines standing at wide distances apart, with glades and vistas between. As is the nature of this Pine with age, its trunk becomes bare of branches, and in several cases advantage has been taken of forming circular flower beds with Ivy sides round their base, in which are planted the more hardy and vigorous Clematis, such as *C. Jackmanii*, *C. flammula*, *C. montana*, and *C. vitalba*, to climb up the stems. These, with the dwarf spring and summer flowers planted in these beds, give a touch of life and colour to these vistas amongst the trees which is particularly pleasing, reminding one of the pretty effect produced in many gardens on the Riviera by planting Banksian and other Roses against old Olive trees in the same way.

Here also there is a charming corner carved out of a bank and a part of the wood. It is approached by massive stone steps, and furnished with carved stone seats, the whole surrounded by banks, beds, and vases of beautiful flowers: a restful corner on a warm summer's day. Further on, at the end of this walk, is a pretty little garden of Heather—truly representative of many Heather-clad hills in the district. Lower down the lawn advantage has been taken of an opening in the face of the wood to indulge in a little picturesque tree planting for colour effect, the Golden Elm, Purple Beech, *Prunus Pissardii*, *Acer negundo variegatum*, and others of attractive colouring being utilised for this purpose. At the base of the lawn, and forming a margin to the wood at this point, a new bamboo garden is being formed, which, in the course of a few years, will not be the least interesting part of the garden, if the many choice varieties which have been planted grow with the same luxuriance as do the many older specimens to be seen in the grounds. On other parts of the lawn handsome specimen Conifers stand alone, adding a dignity and stateliness to the domain. These are presumably forty or more years old, and include, amongst others, *Cedrus deodara*, *Abies Pinsapo*, *A. concolor*, and *Picea orientalis* (very fine), *Cryptomeria japonica*, *Cupressus macrocarpa*, *C. Lawsoniana*, and *Sequoias* (Wellingtonias). Below the lawn is the tennis-court, sheltered on the lower side by the plantation already mentioned, and made attractive on the side next the house by planting the low wall which supports the bank with spring and summer flowers and by a plantation above the wall of flowering shrubs, including many of the best and rarest varieties of *Rhododendrons*.

FLOWER GARDENING.

Of formal flower-gardening there is little, and what there is is confined to the terrace already mentioned. The beds here were planted last summer chiefly with pink and bronze, fibrous-rooted Begonias over carpets of *Alternanthera*, *Mesembryanthemum*, and *Pyrethrum*. If there is not much formal flower gardening, abundant use is made of spring and summer flowers by the introduction in an informal way of numerous beds for Roses.

and spring and summer flowers are introduced into points of vantage in many parts of the lawn, and by the side of walks, where, in association with broad glades of beautiful turf and elegant trees, the effect produced is more pleasing to look upon than when planted together in large groups or masses.

The parts that vases are capable of fulfilling, when artistically-planted and well looked after, in the embellishment of a garden are not, perhaps, sufficiently recognised. Here they are made a leading feature, not only on the terrace, but in many other points of vantage are they placed in the grounds, where flashes of bright colour help to illumine the sombreness of so much green foliage.

The kitchen garden is situated below the tennis court, and is approached by two winding walks skirting the wood on both sides, and is entirely hidden from the pleasure grounds. On the way the visitor passes under many arches that in summer are laden with flowers. In the kitchen garden flowers again dominate the scene, for a central walk, a hundred and forty yards long, is canopied over all its length at short intervals with arches of Roses, Clematis, Loniceras, and many other climbing plants, which, with the wide herbaceous border on either side planted with autumn and summer-flowering plants, present a sight of flower-colouring which may be imagined but cannot easily be described.

The kitchen garden is small, but the most is made of the land. It is never allowed to remain idle; as soon as one crop comes off another is ready for planting. Salad growing is an important item of work. I was agreeably surprised to come across an old Salad plant that I had not seen for years, namely, the rat-tailed Radish. It used to be grown in most gardens thirty years ago. Its long, rat tail-like pods when young taste much like Radish, and are excellent for summer salad and a good substitute for Radish in hot weather, when it is often difficult to have these latter in good condition. They are grown in a row and supported by sticks like Peas. The soil of this garden is very light, composed chiefly of sandy peat, much like that at Wisley. Seeing how well vegetables, and hardy fruit also, succeed in this garden after years of good culture and manuring, I have now confidence that in the course of a few years, under the same processes, the land at Wisley will become equally productive.

The glass department consists of a block of moderate-sized houses built a few years since by Messrs. MacKenzie and Moncur. With the exception of three divisions for fruit (Vines, Melons, and Cucumbers) the whole is devoted to the growth of plants for house and table decoration, such as Palms, Codiaums (Crotons), Cordylines (Dracænas), Ferns, and a host of other plants which are now in request for this purpose.

One division is devoted to winter-flowering Carnations, the varieties favoured being Enchantress, Fair Maid, Mrs. Patten, The Belle, Lady Bountiful, and G. H. Crane. Another is devoted to Begonia Gloire de Lorraine; these and all the other plants were in a most healthy condition. Very good use is made of the old *Campanula pyramidalis* (blue and white) for indoor and out-of-door decoration. I have not seen such good plants of this old favourite since the time I saw the fine specimens Mr. Bruce Findlay used to grow at the Manchester Botanical Gardens years ago. There has been a good deal said for and against Messrs. Sander's new *Nicotianas*, introduced a few years since. Here they are much valued, and are splendidly grown, and are used for indoor and outdoor decoration. The colours are distinct, clear, and brilliant, mauve, pink, and rose.

The pleasure derived from this interesting and well-kept garden is greatly enhanced by the effective services so unassumingly and pleasantly rendered by the head gardener, Mr. James Binnington. O. T.

ORCHID NOTES AND GLEANINGS.

DENDROBIUM DARTOISIANUM.

THIS species described in the *Gardeners' Chronicle*, June 16, 1906, from plants collected by Mr. G. Bronckart in Indo-China in 1905, has lately flowered in Dr. Gordon Paterson's garden, South Lodge, Ascot, and proves to be a close ally of *D. tortile*, and especially of the inferior variety found on the Arracan Hills (see Veitch's *Manual of Orchidaceous Plants*, *Dendrobium*, p. 81). The original *Dendrobium tortile* was illustrated in the issue of the *Gardeners' Chronicle* for December 4, 1847, and the accompanying note states that it was imported by Messrs. Veitch from Java. This is an error, as the species was collected for Messrs. Veitch by Thomas Lobb in the Mergui district in Tenasserim, probably after he had left Java.

The species is recorded from several localities, and the quality of the flowers appear to become poorer in the more northern localities.

D. tortile Dartoisianum differs mainly from the type in its sepals and petals having a yellowish tint, suggestive of the allied *D. Hildebrandii*, but the botanical features, including the short green column, with its deep purple anther-case, agree well with the type, after allowing for even less variation than is known to exist in *D. nobile* and some other species of the group. J. O'B.

DENDROBIUMS AT FIR GRANGE.

DENDROBIUMS flowering in the Orchid houses of W. A. Biney, Esq., Fir Grange, Weybridge Heath (Gardener, Mr. Whitlock), are even more beautiful than in former years, the main house being literally crowded with the beautiful blooms of these spring-flowering Orchids. Prominent in the display are half a dozen specimens of *Dendrobium nobile nobilius* and smaller plants of the pure white, and other leading kinds. The examples of *D. Wardianum* are bearing strong flowering spikes, and among them white forms are seen. Two specimens of the best form of *D. fimbriatum* have their erect slender pseudo-bulbs furnished with graceful sprays of orange-coloured flowers that are tinted in their centres with deep maroon. Exceptionally well-bloomed species, including the showy *D. albo-sanguineum* which many cultivators fail to keep in health, with pseudo-bulbs over a foot in length, and with three to four spikes on each, were noticed. Of the hybrids, the charming *D. Kenneth*, the rare cross between *D. Bensoniæ*, and *D. MacCarthiæ*, raised by Norman C. Cookson, Esq., has probably never appeared before in such beauty as at Fir Grange. The plant is bearing two long pseudo-bulbs that are densely studded with the elegant cream-white, violet-centred flowers, with often five blooms on a single spray. Varieties of *D. Wiganii*, including the yellow *D. W. xanthochilum*, are all luxuriating; a mass of the yellow *D. Melpomene* is covered with bloom; forms of *D. melanodiscus*, *D. xanthocentrum*, *D. Bryan*, *D. Sibyl*, *D. Juno*, *D. splendissimum grandiflorum*, and its numerous allies; *D. Ainsworthii*, Hazelbourne variety, a splendid white form with purple disc; a very richly-coloured *D. Venus*; the pretty *D. Bineyi* (*tortile* × *Ainsworthii*); a magnificent form of *D. Findlayanum*, with a very large labellum the greater part of a deep orange colour, and several other little-known hybrids form part of the display.

Although *Dendrobiums* are the favourite, *Odontoglossums* and other Orchids find a place at Fir Grange, and in a cool house plants of the fine old type of *Cypripedium insigne* are in bloom, together with several of *C. insigne Sanderianum*. Plants of *Odontoglossum crispum* and *O. Pescatorei*, one of the latter bearing flowers with a lip beautifully marked with violet; the scarlet *Ada aurantiaca*, *Colax jugosus*, *Odontoglossum Uro-Skinneri*, *O. Adrianæ*, *O. triumphans*, *Cymbidium eburneum*, &c., and

a very bright *Lælio Cattleya Myra* with others are in bloom in the intermediate house. In the cool *Odontoglossum* house is seen a batch of *Miltonia vexillaria*; the individual plants sending up their spikes in profusion. This plant is usually housed in a warm structure, but it is not often seen in better condition than in the cool house at Fir Grange.

THE ALPINE GARDEN.

GALANTHUS NIVALIS FLAVESCENS

FL. PL.

ALTHOUGH one can hardly say that the so-called "yellow" Snowdrops, i.e., those which have their spathes, ovaries, and deltoid and other markings yellow instead of green, are more beautiful than the white ones, they have yet a brightness and a charm about them which give us pleasant variety.

Of the best-known *G. nivalis lutescens* and the taller and more robust *G. n. flavescens* are among the finest, although existing only in a few gardens.

Still less common is the double form, which came from a Cheshire garden originally, and which has large and pleasing double flowers, even finer, I think, than those of the ordinary double Snowdrop. I received a few bulbs some years ago from the owner of the garden on condition that I did not reveal his name, so that I am debarred from giving the origin of this Snowdrop in a fuller manner. Since that time, it has given me great pleasure, although some of the offsets seem to have reverted to the typical white and green. Still, a few of the bulbs yield flowers with yellow ovaries, spathes, and markings. The outer segments are so open that between them peer the yellow deltoid markings of the inner ones, giving a bright and pleasing effect.

This year one little group of this double "yellow" Snowdrop has produced an offset which has a single bloom, and is exactly the same as the variety called *flavescens*.

As a curiosity, this double variety is welcome, but it has an intrinsic beauty in addition, which will recommend it to those who take pleasure in this flower of the early season. S. Arnott, Sunnymead, Dumfries.

COLCHICUM CROCIFOLIUM.

THERE is a good deal of confusion existing among the *Colchicums*, or Meadow Saffrons, and in writing of one of them under the above name I am doing so with the reservation that I am open to conviction that I am wrong, especially as I have known it for many years as *C. crociflorum*, which is referred to *C. alpinum* by modern authorities; while Mr. Baker gives *C. crociflorum* as apparently synonymous with *C. montanum*, and *C. crocifolium* as a form of the same species. The name of *crocifolium* answers better to the character of the foliage than does that of *crociflorum* to the flower.

Whatever the name, however, this is one of the most distinct of the small Meadow Saffrons, and its value is increased by its coming into flower in the early days of the year. Sometimes if one orders *C. crociflorum* or *C. crocifolium* one receives a purple-flowered plant of greater dimensions, but not distinct from *C. alpinum*, and to all appearance a form of that plant; while the one under notice has a smaller and more beautiful bloom, which is white, prettily lined with dark purple, almost black, on the exterior of the segments. The leaves, which appear in spring, are narrow and more *Crocus*-like than those of the other plant. This is a comparatively scarce *Colchicum*, and one which, were it a little cheaper, might be worth planting in quantity, but for one fault. This is that the flowers are keenly sought after (if one may use the term as applied to gastropods) by slugs and snails, and it is difficult to ward off these vermin. They seem to scent this *Colchi-*

cum afar off, and its attraction to them is evidently as great as is that of *Bulbocodium vernum*. I find nothing so serviceable as a notched zinc ring, or one made of brass wire gauze placed round the plants and sunk deeply enough in the soil to prevent the slugs from entering beneath the ring.

This *Colchicum* flowered with me in February this year, but in milder seasons I have had it in flower in January. *S. Arnott, Sunnymead, Dumfries.*

SEEDLING HIPPEASTRUMS AT OAKWOOD, WYLAM.

THE *Hippeastrums* illustrated at fig. 88 represent a batch of seedlings raised at Oakwood during the past three or four years. Mr. Cookson, the owner of Oakwood, purchased the two varieties Queen Alexandra and Mrs. Bilney, both of which received an Award of Merit from the Royal Horticultural Society on April 22, 1902, and intercrossed them, the offspring being the striped and

able during January and February, in which months nearly 200 plants were in flower. I have recently been successful in flowering plants of *Hippeastrum* × *Vallota*. They are exceedingly useful and like a miniature scarlet *Hippeastrum*, the *Vallota* parent being more pronounced in the habit of growth. The flowers of these hybrids have not shown much variation in colour, the most remarkable being some of pure white. *H. J. Chapman.*

FOREIGN CORRESPONDENCE.

EREMURUS CHINENSIS.

THE *Eremuri* are distributed principally throughout Russian Central Asia and Persia: a few are found in West Asia, the Caucasus, and the Crimea, the Altai, the Himalaya and British India. None has previously been known from East Asia.

Great was my astonishment, therefore, when

those where Pratt found it, in the province Kansu, June 26, 1885 (village Tsui-tsei, below Siguchen), and in the Province Szechuan, July 15, 1893, between Va-sy-kau and Tsa-li, and July 26, 1893, in the valley of the river Siao-dshin, between the villages of E-za and Pany-sha-myr.

Potanin's samples all have roots (which consist of fleshy, stout, fusiform fibres), leaves, and are all in fruit. However, to one of them was hanging a clump of dry flowers. Crushed though they were, they showed that the plant was really an *Eremurus*, and, moreover, different from any one known before.

The flowers are about the size of those of *E. Olgæ*, but have narrower segments. The filaments are very thin above, gradually a little broader towards the base. The spikes bear fewer flowers than those of *E. Olgæ*. The pedicels are more horizontal, curved near the capsules, which are erect. The bracts are naked, short, broad at the base and thin from about one-third of their length. The leaves are

FIG. 88.—MR. N. C. COOKSON'S HYBRID HIPPEASTRUMS.

blotched varieties represented in fig. 88. Many of the plants, although flowering for the first time, have developed two scapes with four flowers each, the individual flowers being fine in substance and form, and many of them measuring 8 inches in diameter. The colouring has shown a remarkable variation, some had deep orange-red blotches, whilst others possessed various purple shades. The darker flowers are the result of intercrossing a purple seedling with the variety Plato, and several from this cross have been remarkable for the absence in the flowers of the green markings usually seen at the base of the tube, the green being replaced by a deep purple shade that is continued to the base of the flowers. No special facilities exist at Oakwood for growing the plants; they develop their growth in the stove, and when this is finished they are removed to an exposed position in the greenhouse to become matured by the time the house is required for winter-flowering plants. The flowers are found especially service-

my son, Boris Fedtschenko, Chief Botanist of the Imperial Botanic Garden here, who, during his journey abroad last summer, took notes for me on the *Eremuri* of the principal herbaria of London, Paris, and Geneva, brought me a sketch and description of a plant, gathered by Pratt, June 9, 1891 (Nos. 144 and 728), in China (W. Szechuan and Tibetan frontier, chiefly near Tachienlu). The plant consisted of spikes in fruit and leaves, flowers and roots being absent; it reminded me in its habit of *Eremurus sogdianus*, but was certainly different from it. Further information, which was kindly given me at the Royal Gardens, Kew, led me to believe that the plant was nearer to *E. Olgæ*. However, the roots and flowers being wanting, I could not identify the plant, until I received, about two months ago, from Mr. W. Komarow (of the Imperial Botanic Garden), who is studying the Chinese herbaria here, three specimens of the same species, gathered in 1885 and 1893, by our famous explorer in Mongolia and China, G. N. Potanin, in nearly the same localities as

very different from those of all other species: they are keeled, but thin and flaccid; in one sample they are very narrow (2½ to 3 millimetres), in the two others they attain 10½ millimetres, are broadest at about one-third of their length, and from there gradually diminish upwards, and are filiform at the end. They are naked on both sides and also on both edges, and have a stout nerve on the edges. The whole plant is about 65 to 75 centimetres high; the spike in fruit on the largest sample more than 40 centimetres long, and 6½ centimetres broad; the stem about 5 millimetres thick.

The roots in two of the samples are normal; the third presents a curious anomaly: each new ring of fibres stands 1 or 2 centimetres higher than the older roots. I can explain this fact only by supposing that the crown of the plant has been overwhelmed by sand or buried by mountain debris, and that the new roots of two consecutive years have tried to grow nearer to the surface of the earth.

The description and figure of this interesting

new species will be given in my large work on the *Eremurus*, which is in the press and will appear in the *Mémoires de l'Académie Impériale des Sciences de St. Petersburg*. In sending these lines to the *Gardeners' Chronicle*, I wish to bring the new plant before the attention of those who have the opportunity of gathering plants in China: perhaps someone may be so fortunate as to gather the plant at an earlier season, when it may be found in flower, and he will then be so kind as to send me some dry (herbarium) specimens of it. *Olga Fedtschenko, St. Petersburg, Imperial Botanic Garden, March 5 (February 20), 1907.*

FASTIGIATE TREES.

(Concluded from page 185.)

EVERGREEN VARIETIES.

ABIES PECTINATA PYRAMIDALIS.—So far as I have been able to judge, this variety of the Silver Fir is very uncommon in Britain. I had not met with it until two years ago, when I saw it in the Arboretum of the late Mons. Lavallée, at Segrez, France. Here there is a very striking specimen 30 feet high, narrowly pyramidal, and tapering to a fine point like a spire. In the valley of the lower Thames the Silver Fir grows so badly that it would not be worth while to plant this variety there. But where it would succeed, as in most of the Scottish gardens, it would make a welcome change from the Irish Yew, the erect Lawson Cypress, and the few other evergreen trees of this class.

TAXUS BACCATA FASTIGIATA (IRISH YEW).—The best-known and most valuable of all evergreen fastigate trees is the Irish Yew. It is especially useful for forming minor avenues within the garden, and as "sentinel" trees guarding the entrance to formal gardens, etc. It can, indeed, be only used in more or less formal arrangements, especially in a young state, when it grows in the form of a very slender cone. Old trees become cup or vase-shaped. The variety originated at Florence Court, in Ireland. It differs from the common Yew not only in habit, but also in the arrangement of the leaves, which, instead of being in two opposite rows, are set all round the shoots. Of several sub-varieties, the "Golden Irish Yew" is the best, its leaves being edged with bright golden yellow. The "Silver Irish Yew" is a poor thing. The best way to propagate the Irish Yew is by cuttings, but a certain proportion of its seeds come true.

CUPRESSUS LAWSONIANA.—There is quite a distinct group of erect-growing varieties of the Lawson Cypress, some of which are very useful. One of the most popular of these is *erecta-viridis*, sent out many years ago, I believe, from the Knap Hill Nursery. In our colder latitudes it makes the best substitute for the Cypress of Southern Europe (*C. sempervirens*), whose dark, columnar shape forms one of the most characteristic features of Italian gardens. The variety *Allumi*, or *Fraseri*, is distinct and handsome, not only for the erect mode of growth, but also for the fine glaucous hue of its foliage. Var. *Wisselii* is a curious plant of dwarf yet erect habit, strangely distinct from the type, and resembling some of the dwarf forms of *Cupressus* (*Retinispora*) *obtus*.

PINUS.—There are but few instances of fastigate growth among the Pines. The Scots Pine (*P. sylvestris*) has, however, sported into an erect form of tapering, spire-like habit. There is also a variety of *P. Laricio* (the Corsican Pine), which, whilst not exactly fastigate, still differs from the type in its main branches, taking a vertical instead of a horizontal direction. This variety is grown at Kew as *Pallasiana*. Large masses of the same variety (grown as *caramanica*) in the woods of Les Barres, and planted over 60 years ago by one of the De Vilmorins, show the same character in the more frequent forking of the trunk, although

the trees are grown, like other varieties, only a few feet apart.

JUNIPERUS COMMUNIS FASTIGIATA.—This, the Irish Juniper (often called *J. hibernica*), is an old and well-known plant in formal gardens. It is, perhaps, the most purely columnar of all trees hardy in this country, its diameter varying but little from bottom to top. In a small

FIG. 89.
PYRAMIDAL FORM OF THUYA PLICATA (GIGANTEA).

state it is peculiarly dense and rigid—in fact, almost solid—and one of the most remarkable of this class of plants. The finest specimens I have seen are in Scottish gardens: at Abercairney, in Perthshire, for instance, there is a specimen forming a rigid column 20 feet high and 3 feet through, and there is another fine example in the gardens of Scone Palace. This

variety preserves the light greyish colour of the type.

CEPHALOTAXUS PEDUNCULATA FASTIGIATA.—As a companion tree to the Irish Yew, this upright *Cephalotaxus* is well worth growing. Its leaves, however, are larger, and in habit it is broader and sturdier. The arrangement of the leaves on the branchlets is also the same, being set all round, as they are in the Irish Yew, and not in the two opposite rows of the type. It does not, apparently, grow so fast or so tall as the Irish Yew, and for certain positions in formal arrangements it may be preferable to it. Once considered a distinct species, it was named *C. Burgeri*. In gardens it is also known sometimes as *Taxus japonica*, and has been called a *Podocarpus*.

THUYA GIGANTEA PYRAMIDALIS.—Among the Conifers with an erect Cypress-like habit, this is one of the best. The specimen illustrated (fig. 89) was sent to Kew by the late Mr. Harry Turner, of Slough, who thought highly of it. It is now 15 feet high. Although not a well-known plant, it is a very worthy companion to the erect variety of Lawson's Cypress.

BUXUS SEMPERVIRENS PYRAMIDALIS.—Grown as an isolated plant, or associated in the ordinary way with other shrubs, this variety of the common Box is hardly worth its room, being stiff and inelegant, without the distinctive formal character of a good fastigate plant. It has, however, proved useful as a hedge plant, and a hedge of Box is a pleasing change from the few other evergreen plants that can be used for the purpose.

It is probable there are fastigate forms of other common trees in the country not yet known in commerce. For instance, Mr. W. Goldring has lately informed me that there is a fastigate Spanish Chestnut at Mount Mascal, Bexley, but I do not know any such forms of the following:—Sycamore, Ash, Turkey Oak, Durmast Oak (*Quercus sessiliflora*), Laburnum, Walnut, Pear, and Apple. There is a variety of Lime known as *pyramidalis*, but I do not know of a really fastigate one. And there are also some of the seedling forms of *Lucombe Oak* that have a markedly pyramidal shape when young. *W. J. Bean, Kew.*

THE PRUNING OF ROSES.

(Concluded from page 182.)

AYRSHIRE Roses are of true running or rambling habit, and as isolated specimens on lawns I have seen some of them as most beautiful objects worked on stems 8 to 10 feet high. They are equally useful for covering unsightly buildings, old tree stumps, &c. The weakest growths require to be thinned out; also the soft tips should be removed from the vigorous shoots at the end of March.

Boursault Roses, of which *Amadis* and *Inermis* are thornless, blooming in immense clusters, were the two first Roses to be impressed on my mind. This type requires very little pruning. Keep them well thinned, and cut away all dead wood, removing also the tips from very vigorous shoots.

POLYANTHA ROSES.

Polyantha Perpetual, of which *Gloire des Polyantha*, *Mignonette*, *Schneewittchen*, &c., are types, vary little in growth. Like the Hybrid Perpetuals, they are short and compact, and will be all the better for close pruning. April will be soon enough to commence, cutting the strong shoots back to 3 or 4 eyes, and dealing with the weaker shoots correspondingly.

If I were writing a description of Roses generally, I would give the beautiful *Lucida* a prominent place; the duplex variety is attractive and beautiful. Little is required in the way of pruning beyond thinning and regulating its branches.

Rosa rugosa, and its many hybrids, are exceedingly hardy, and the handsome seed

pod follow equally attractive flowers. All that is really necessary in this section is to thin out the shoots occasionally and to shorten the long, straggling shoots in order to give symmetry to the bushes. Such work may be done during the present month.

Chinese, Monthly, or Bengal Roses are more variable than those of any other class. Unless the operator has a distinct knowledge of the variety he is dealing with, he cannot suitably prune them. Generally speaking, the old shoots should be thinned out in the autumn, and the strong shoots shortened to 12 inches early in April: the medium-sized ones to 8 inches, and the weakest to 3 or 4 inches; but, as an instance, it would not do to prune the common China or Monthly Rose in the same way as you would treat Laurette Messimy, or Aurore and Madame Eugène Resal. Queen Mab again is distinctly different in its requirements to the beautiful

Ophirie are types, and these should not be pruned until April. Thin out the weak shoots, and shorten the tips of the strong ones. In the case of dwarf varieties hard pruning is detrimental, and if the strong shoots are cut back to 1 foot in length and the medium and weak shoots to 8 and 3 inches respectively, that is all that is required.

Scotch Roses of both double and single flowered varieties form excellent hedges, and as their growth is of a close nature, the weakest should be removed and the long shoots slightly shortened.

Hybrid Sweet Briars, in these gardens, form a screen upon Fir poles and stout galvanised wire. Some of the growths reach a height of 12 to 18 feet, and no more beautiful sight can be imagined than these when they are in full bloom. After the flowering period, many growths may be cut out, or the work may be done at the present time, thinning out the weaker shoots and shortening those that are more vigorous.

Where large single and isolated specimen Roses are required, standing out alone with plenty of light and air about them, they are as a rule best left unpruned. The growths, when too crowded, may be readily staked out. This form of growing Roses might be more frequently practised on the grass. It is the more natural, and compensates the cultivator with a rich display of flowers. *W. H. Clarke, Aston Rowant, Oxon.*

SIDE-GRAFTING.

CONSIDERING the advantages derived from this method of grafting, it should be more often practised by the fruit-grower.

Frequently the shape of a tree is spoiled owing to the absence of one or more branches which cannot be replaced by any system of pruning.

This is particularly noticeable in trees that have been negligently pruned in their earlier stages of growth—when the foundation of a well-balanced tree should be laid in weak-growing varieties, and also in those of a straggling habit.

Side-grafting is as easily performed as the ordinary crown-grafting.

The scion should be of fairly strong wood, taken from the same tree as it is to be inserted on or from another of the same variety, and should be about 6 inches in length.

A slightly curved scion is preferable, and it should be cut so that when it is grafted the top bud points outward from the centre of the tree. In selecting a position for inserting the graft, choose a branch as near to the outside of the tree as is possible, and in the bark of this branch, facing in the same direction, cut a T-shaped incision, making the transverse cut uppermost.

If the edges of the bark are then slightly lifted with the handle of a budding knife, the scion, which should be previously prepared, can be easily pushed into position.

A piece of strong bast should be bound round the graft, but it must not be tied too tightly, and a band of clay or grafting wax will finish the operation.

If a few strands of bast are tied around the clay, they will serve to keep it together.

The best season for this method of grafting is in March or April, when the sap is on the move, but I have had very good results in the case of Apple trees by grafting early in May. The scions in this latter case should be taken in winter, and be laid in on a north border till required.

As the buds on the scion develop into growth a small stick should be tied to the main branch to afford support, and to minimise the risk of damage by wind. *Chas. Jones, Norwood Villa, Bournemouth.*

VEGETABLES.

STRINGLESS AND HARICOT BEANS.

In most homes in this country Beans are sliced before being cooked, but this is not necessary with

the stringless and Haricot Beans; indeed, not with any if the pods are gathered young and cooked whole. This is worth noting, as by allowing the French or runner Bean to get matured and then cutting up the pods much of the quality is lost; far better cook them when quite young. By doing this less strain is imposed on the plants, and they are therefore capable of yielding a longer time. If addressed to market-growers I fear my advice would meet with little favour as the pods are liable to receive rather rough treatment, but in private gardens this is not the case. On the Continent the Bean is regularly served whole, and is delicious. It is cooked in several ways and made most tempting to the palate. The pods cooked young are much greener and far more tender. The stringless podded Beans are much rounder than the ordinary kinds and more fleshy. The seeds are less prominent, and they remain tender for a longer time than the flatter kinds. The plants also have a more branching habit, and are enormous croppers. The plants like a rich rooting medium, and liberal supplies of moisture in dry weather; damping

FIG. 90.—SIDE-GRAFTING, SHOWING THE INSERTED SCION.

FIG. 91.—SIDE-GRAFTING, SHOWING THE ADDITION OF THE CLAY.

new Field Marshal recently sent out by Messrs. Wm. Paul & Sons. Before pruning this class of Rose consider very carefully the habit of each individual variety and prune it accordingly.

Bourbon Roses have been increased largely in recent years. Many of them are very strong growers, the variety Robusta being an example. In such cases the extra strong shoots emanating from the base require shortening one-third their length, and existing and permanent growths covering walls, &c., should have the new shoots pruned to 3 eyes. The weaker and more bushy kinds should be pruned somewhat more severely.

The true Noisette Roses, being very hardy, are particularly free growers and bloomers, often continuing in flower for months together. They may be divided into two distinct sections—the climbing and dwarf growers. Of the former type, W. A. Richardson, Bouquet d'Or, and

overhead late in the day will greatly benefit the dwarf kinds, but as their culture is so simple I need not enumerate the details. I advise two or three sowings, the first to be made in April, the second in June, and the third early in August, using the dwarf kinds for the last sowing. There should then be a succession of good pods from May till October.

In mentioning a few reliable kinds I will note the climbing varieties first. These are not numerous, and they are closely allied to the dwarf type. Two very good stringless Beans grown last season included Carter's "July," which was not unlike the Butter Bean in form, the pod being very fleshy and of medium size, the seeds very small, and the plant freely productive. This is a delicious Bean when cooked whole, and it does not get old so quickly as a non-stringless Bean. The older Princess—a small, white-seeded variety—is well worth a trial. The pods are not large but stringless, and when nearly full grown are excellent when cooked whole, but I do not mean when the seeds have

matured. They have a delicate flavour, and do not grow so tall as the ordinary runner; for gardens limited in size they are most useful. The tall Sugar Bean is closely allied to this one, being very fleshy and stringless.

Of dwarf kinds there are many good ones. Sutton's Perfection is a splendid variety, with pods almost round, extremely fleshy and succulent. The plants branch and crop freely. Another of the same type, named Plentiful, is a good early stringless variety having a long, broad pod, and it is a great cropper; a grand Bean for sowing in April or June. The dwarf Holborn Wonder is also a good Bean on account of its deep green pods and its great cropping qualities. It is not unlike the Canadian Glory in size and good cooking qualities. Canadian Glory is one of the best forcers in this section: the pods are quite stringless.

Though somewhat different from any of the above there is a very fine type of dwarf Bean grown under the name of Green Gem; this is a great favourite in the Paris market, and it is a splendid Bean when gathered young, and cooked whole. The seeds are pale green and are much liked in a dry state on this account.

The Haricots are not great favourites in this country, but they are valuable. The large, white Haricot has a long broad pod, with good sized seed produced in abundance, which are appreciated in a dry state. The miniature Haricot is worth a trial, being a dwarf variety and more branching. It is later than the large white, but the plants yield a great crop of small tender pods which are delicious when cooked whole, and the dried Beans are useful for consumption in winter. G. Wythes.

POTATO TRIALS AT WISLEY.

The council of the Royal Horticultural Society having again this year emphasised their previous instruction to the Fruit and Vegetable Committee, that, with several other vegetables, no awards can be made to Potatoes until grown for trial at Wisley, it may well be hoped, first, that Potato raisers will please note the uselessness henceforth of sending samples of new or other varieties to the Horticultural Hall for award; also that the council, in thus insisting on such Wisley trials, will spare no expense to see that such trials shall be full and complete. Those persons who saw the interesting trials of Potatoes carried out last year by Messrs. Sutton & Sons, at Reading, could but wonder why others, on a similar scale, were not conducted on the R.H.S. ground at Wisley.

Now that a scientific gentleman has been appointed at Wisley, is it not possible for him to co-operate with the superintendent, Mr. Wright, and to devise some trials that shall have a distinct bearing on the interesting subject of the comparative deterioration in reproductiveness of southern-grown and planted tubers, especially as compared with tubers of similar varieties grown in Scotland, the Midlands, and Ireland? A matter of the very highest importance to southern Potato growers.

A start might be made this year in testing the relative value of the planting for seed purposes of immature or unripe tubers as compared with ripened tubers. To this end rows of new varieties, with some old ones, for comparison, and also rows of selected varieties obtained from the south of England, the Midlands, Scotland, Ireland, and other sources should be planted for comparison. Also there should still be planted separately short rows of 10 or 12 selected varieties, of which two rows of each variety should be provided, the tubers of the one row being lifted at the end of August or thereabouts, whilst the tops are still vigorous, and the skins of the tubers thin and tender, the tubers being saved and wintered; the other duplicate row being left to ripen fully, and the tubers lifted and stored also, both lots being replanted side by side in the following spring. Were such trials undertaken at Wisley we should have Potato trials of exceptional interest, and such as probably no other garden or field product so urgently needs. We must remember that a great home supply of Potatoes is a matter of the highest national importance, and certainly merits as much encouragement at the hands of our great horticultural society as do products from our highly-favoured colonies, perhaps, indeed, very much more.

Potato shows may be useful in their way, but trials of the nature indicated have far greater value. There is a fine soil, pure air, and ample room at Wisley. A. D.

The Week's Work.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower to Sir Trevor Lawrence, Bart., Burford, Surrey.

Seed-saving.—Those plants of the deciduous *Calanthes* which are bearing seed-capsules should be placed in a sunny position to mature and ripen the seed, and where the young growths have started they should be protected by a sheet of tissue paper. Immediately the pods appear to be bursting, tie some tissue paper around them to prevent loss of seed. When the seed is ripe, and the old flower stem commences to die down, cut the pod off and carefully preserve it in a dry place until the earlier potted plants are rooting freely, when the seed may be sown thinly over the surface of the compost. Keep the seed moist afterwards by means of the fine sprayer, and when they have commenced to grow, treat them as was advised in my last calendar for the older examples, but do not disturb them until after the resting season. Seedlings raised last year may now be pricked off.

Habenaria militaris, H. rhodochila, H. Susanna, H. carnea, and the pure white variety *nivosa*, now commencing to grow, should have the tubers turned out of their pots for re-potting. Those which have been grown and rested properly will have increased in numbers, and will require to be carefully divided, selecting the largest and strongest tubers for re-potting singly into pots, those known as long thumbs or medium 60's being the most suitable, but proportionately smaller pots may be used for the others. Several of the smaller tubers may be placed at equal distances apart in one pot. Place each tuber in an upright position, with its base resting upon the crocks which are used for drainage, the growing point being just below the rim of the pot. Fill up around the tuber with clean broken crocks to within 1 inch or 1½ inches from the top. Being surface-rooting plants, these *Habenarias* require very little depth of soil. It should consist of fibrous loam and peat in equal parts, adding some chopped sphagnum-moss, crocks broken up small, and coarse silver sand, and mixing all these ingredients together. When potting, press the materials down moderately firm, just covering the tuber so that its point may be seen through the compost. An occasional sprinkling with the fine sprayer will supply sufficient water until some growth has been made, when the quantity of water should be gradually increased until the plants are in full growth, when they require an almost unlimited quantity. Much heat should be afforded the plants during the growing period, and a position as near to the roof-glass as possible, employing only a thin shade whenever scorching of the leaves is feared owing to bright sunshine. Syringe the under sides of the leaves pretty frequently.

The new Bonatea (Habenaria) Uganda will thrive under similar treatment. Plants now starting into growth will require rather large pots or pans in order to afford sufficient room for the unusually large tubers to develop properly. Growth will be very rapid, and when the flower spikes, which are terminal, appear, the plant should be gradually inured to a cooler atmosphere, and the flowers, if allowed to open in a sunny position in the intermediate house, will be of better substance than if left in the warmer division.

PLANTS UNDER GLASS.

By J. G. WESTON, Gardener to H. J. KING, Esq., Eastwell Park, Kent.

The affording of water.—At this season of the year many plants are being repotted, some after a long season of rest, and that have at present little or no foliage to support. If the soil is in a proper condition of moisture at the time of using, such plants require no water, except such as they get from overhead spraying, until growth has commenced, and the roots are consequently active. Others having a moderate amount of foliage upon them must not be allowed to remain dry, although it is far better to err on this side in the case of newly-potted plants than to over-water them. If too much water is afforded, the soil soon becomes sour, and many plants never perfectly recover health. It is not too much to say that more newly-potted plants in pots are killed by over-watering

than by any other cause. Young men should think out for themselves the relation between the amount of foliage or bloom on the plant and the requirements of the roots, whether the plant is in full growth or not, and whether the pots are large or small. Unless a man studies the art of watering, he will never be a successful plant-grower. Many plants in pots, such as Palms, Cordylines, and similar strong-growing plants, perhaps standing in the same pot for years together, seldom or never have sufficient water; also grasses like *Isolepis*, *Panicum*, &c., &c., usually in small pots, should never be allowed to become really dry when in full growth.

Anthuriums.—Any plants requiring a shift may now be repotted, using a loose porous compost, consisting of two parts peat and one part turfy loam, with the addition of charcoal, crocks, sphagnum-moss, and sand. The pots or pans used may be half-filled with crocks, as perfect drainage is essential to the health of these plants. The ornamental-leaved section, of which *A. crystallinum*, *A. c. illustre*, *A. Veitchii*, and *A. Warocqueanum* are good examples, are handsome as specimen plants for the stove. They should be afforded a position where they can be shaded always from bright sunshine. Every care should be taken to keep the leaves clean, and free from insect pests, for even in sponging the plants it is difficult to avoid injuring the leaves. A fortnightly spraying with a good insecticide at moderate strength will be found the best means of keeping them clean. A thoroughly moist atmosphere is necessary, especially all through the growing season. The flowering section, grown for their brilliant-coloured spathes, are represented generally by varieties of *A. Andreanum* and *A. Scherzerianum*, the latter being the most useful, the plants, if in good health, flowering continuously over the whole season. Handle the plants carefully when potting them, as the roots are always more or less active, and should not be broken more than necessary. Any sour soil about the roots should be washed away. In repotting keep the crowns well above the compost.

THE HARDY FRUIT GARDEN.

By J. MAYNE, Gardener to the Hon. MARK ROLLE, Bickton, East Devon.

Strawberry beds.—The plants are beginning to develop new growth. Contrary to the general practice, we always fork-in the manure between the plants at about this date, and have found no ill-effects to follow. Most soils require this treatment at the least once a year, owing to the frequent treading during the gathering of the fruit in mid-summer, especially if at such a time the weather is showery. Shallow digging also allows the spring showers to penetrate to the roots more evenly, and permits the sun and air to sweeten and aerate the ground. A quicker growth is thus promoted.

Alpine Strawberries deteriorate after a few years if increased by layers. Much better results are obtained from seedlings, and the same remarks apply to the "perpetual" fruiting varieties *St. Antoine de Padoue* and *St. Joseph*. The seed may either be sown in shallow boxes or in a cold frame, and the seedlings, when fit to handle, should be pricked out in frames, or on a warm border, at distances of 2 to 3 inches apart, and finally transplanted at a foot or 15 inches asunder. Such seedlings will bear fruit from August until November in the following year. All flower-spikes and runners should be cut off up to the middle of July, or even later, if it is wished to lengthen the supply of ripe fruits.

Mulchings.—Where a heavy surfacing of manure was spread over the roots of newly-planted fruit trees as a protection from hard frost, the material should now be cleared away and the soil lightly loosened by means of the fork, so that the sun's rays may the better accelerate root action. This mulch may be renewed two months later if it is considered necessary for the welfare of the tree.

The thinning of blossom-buds.—Some cultivators recommend the removal of some of the blossoms when they are in any degree crowded, considering it is an extra strain upon trees to allow all to expand, when perhaps only 5 per cent. are necessary to produce a full crop, provided of course that most of these latter set and swell satisfactorily. This may be good practice under glass, but, considering the fickle weather characteristic of spring, it would be

dangerous to adopt it generally in the case of outdoor fruit trees, except in respect to Peaches and Apricots, which, having no stem to their fruit, often set, but become deformed whilst swelling owing to pressure between the branch and the wall. The only flowers that I think may be safely dispensed with are those that facing inwards would have little or no space to develop if a satisfactory "set" was obtained.

The Apple store.—It is getting late to see firm fruits of British-grown Apples, but there are several varieties that will still compare favourably with foreign or Colonial produce. Such are Blenheim Pippin, Adam's Pearmain, Beauty of Kent, Alfriston, Newton Wonder, Bramley's Seedling, Annie Elizabeth, Claygate Pearmain, and Sturmer Pippin. Those intending to graft would do well to use scions of these varieties. To verify my statement, I am forwarding a fruit of each variety to the Editor of this journal.

THE FLOWER GARDEN.

By A. C. BARTLETT, Gardener to Mrs. FORD, Pencarrow Cornwall.

Protective materials may now be removed from most of the half-hardy plants and shrubs. Such subjects as have been heavily-covered should be gradually exposed. The leaves of Kniphofias which were tied up over the crowns should be unfastened. Cut away the dead ends of Pampas Grass leaves, trimming the clumps into shape. As the Gunneras show signs of growth uncover the crowns, but keep some protective material at hand for use next month, as the tender young leaves are easily damaged by frost. An occasional dressing with nitrate of soda during the growing period will materially increase the size of the leaves.

The flower beds will now require frequent attention. Where necessary, afford neat stakes to the Hyacinth spikes and many species of Tulips. Wind-broken flowers should be at once cleared away. A mulch of cocoa-nut fibre will prevent the rains from disfiguring the leaves by splashing the soil on them. If bordered by grass, the edge of the beds should be frequently clipped. Where there were not enough reserve plants to make good the winter losses—which have been unexpectedly large this season—blanks may be made good with sprays of Mahonia (*Berberis aquifolium*), which is now coming into flower. If pressed firmly into the ground, the sprays will keep fresh for a long time. For any special occasion short branches of Laurustinus may be similarly used, but it is comparatively short-lived.

Bedding Pelargoniums, &c.—Remove the earlier batches to a cool house preparatory to transferring them to cool pits after a week or so. Frequently pinch the leading shoots of standard Fuchsias and Heliotropes. Do not allow such ornamental foliage plants as the Castor Oils (*Ricinis*), Cannabiss, Eucalyptus, &c., to become pot-bound. Complete the propagation of Iresines, Alternantheras, &c., at an early date.

Pruning.—Ivies which have furnished their allotted space should be cut hard back to the walls. Where there is space to be filled see that the shoots are securely fixed to the walls before the clipping is done. Shrubs which require severe pruning should now be given attention. Clip box-edgings and cut back borderings of St. John's Wort, which are already of full size, or this year's growth will make them too wide.

FRUITS UNDER GLASS.

By ALEXANDER KIRK, Gardener to J. THOMSON PATON, Esq., Norwood, Alloa, Clackmannanshire.

Pineapples.—Plants which are coming into flower require a dry atmosphere at a temperature of 70°, and a bottom heat of 80°; close the structure with sun heat at 90° early in the afternoon. Afford the plants warmed manure water once a week. As soon as the fruits begin to colour, lessen the supply of water at the roots, ultimately discontinuing it altogether. Succession-plants should have a moist atmosphere and regular degree of heat. Damp the paths frequently, and admit air only during sunny weather. Examine the plunging material, and if it is found to be dry, apply a good watering. Be careful not to overwater the plants.

Early Peaches and Nectarines.—The trees must not be unduly hurried whilst the fruits are stoning. Do not let the atmospheric tem-

perature exceed 65° at night and 75° by day until the fruits commence to swell for the second time, after which time the heat may be increased. Admit air daily when the weather is favourable, and keep the atmosphere of the house moist by closing early in the afternoon. Syringe the trees once or twice daily. Tie the young shoots to the trellis, and do not overcrowd them, but expose them to the light as much as possible. Extra strong shoots should be cut out. Thin out any fruits that are not needed, but were overlooked at the previous thinning; a space of about 9 inches should be allowed between each fruit, notwithstanding that a few fruits may drop during "stoning." Always select fruits for ripening which are on the sunny side of the shoot. Test the borders, and apply tepid manure water if necessary.

Peach or Nectarine trees in flower may be easily injured if exposed to currents of cold air. Apply fire heat only during night time. Pollinate the flowers at midday with a rabbit's tail, and give the trees a sharp rap with the hand at the same time. Keep the atmosphere rather dry, and the temperature at night 55° to 60°, allowing it to rise to 70° by day. A light fumigation with XL-All is an effectual cure for green fly, which must not be allowed to spread.

Cucumbers.—Plants in pits should have a compost of rich turfy loam, leafmould, and mushroom-bed manure, well mixed together and placed in a ridge in the pit to the depth of 12 or 15 inches. Plant on the top of this ridge, and increase the atmospheric temperature to 70° at night, allowing a rise of 10° by sun-heat during the day. Shut up and damp down the pits early in the afternoon. Plants now bearing fruit will require liquid manure twice a week. Pinch and tie-in the lateral growths, and keep the atmosphere moist. For Cucumber culture in frames, collect stable manure and leaves and throw them into a heap to ferment. Turn the material daily, and allow the excessive heat to escape, and the manure and leaves to sweeten before they are used for the Cucumbers. Sow seeds for raising succession plants.

THE KITCHEN GARDEN.

By WILLIAM H. HONESS, Gardener to C. COMBE, Esq., Cobham Park, Surrey.

Peas.—Sowings in larger quantities should now be made of the varieties of the second early section. I would strongly recommend that Superlative be given a trial. It grows 4 feet in height, is of robust habit, and yields an enormous crop. It was greatly admired here last season by all who saw it. Further sowings should be made at intervals of a fortnight, selecting those varieties which are known to succeed best in the district, but adding one or two of more recent introduction for the purpose of trial. Few vegetables have been improved more than Peas, and most of the principal seed-firms have introduced some superior sorts. Novelties are to be found every season in the lists, and the gardener should make a trial of them as far as circumstances will permit.

Early Peas.—Plants from earlier sowings now appearing through the ground, will need to be closely watched and protected from birds and slugs. A sprinkling of wood ashes or soot, and the use of Pea guards or strands of black cotton along the rows, will prove of great assistance in keeping these pests in check during the early stages of growth. Those that have been sown in pot, turves, &c., and thoroughly hardened, will now be quite fit for planting out if this has not already been done. The practice of sowing Spinach between rows of Peas is pretty general, and may be recommended. If it be followed, a good supply of this valuable vegetable will be obtainable throughout the summer.

Lettuce.—Continue to prick out plants from the earlier sowings. Make periodical sowings of both the Cabbage and Cos varieties in the open, according to the demand.

Radishes.—We have been using Radishes obtained from sowings made in the latter part of December last between rows of Potatoes in slightly heated pits.

Herbs.—Annual species such as Basil, Marjoram, Chervil, &c., and in some instances the perennials, where it is necessary to grow these from seed, should now be sown. It is advisable to have a good selection of herbs in cultivation,

and thus be prepared for a casual request; sow the seeds in lines, and subsequently thin out the plants as required. Little else will be required to keep up a small supply of those herbs that are seldom asked for.

French Beans that were sown, as advised in a previous calendar, for planting out in cold frames, or in houses, should now be given cooler treatment to harden them before they are removed to their permanent quarters. Great care must be exercised in handling the plants during the process of transplanting, which should be undertaken as soon as they are considered hard enough. The young plants, being extremely tender, are easily bruised and spoilt. Attention must afterwards be given to the provision of shading during the first few days, or until root-action takes place. Afford the plants protection at night time when frost appears likely, as they will be liable to suffer injury from this cause for some time to come.

PUBLIC PARKS AND GARDENS.

By W. W. PETTINGREW, Superintendent of the Parks and Open Spaces in the City of Cardiff.

PREPARING FOR SUMMER GAMES.

In recreation grounds where the area is so restricted as to make it impossible to set aside special portions of the ground for summer and winter games, it is very necessary for the preservation of anything like a good sward to allow the ground to have a period of complete rest between the football and cricket seasons. In a great number of public parks this useful practice is not observed, simply because Park Bye-laws do not, as a rule, make any provision for this. The case is, however, one of many where the highest interests of everyone concerned are best served by taking for granted the right of the Council to impose restrictions upon the public for the public's good.

Practical measure.—From about the third week of March till the second week in May we prevent the playing of games upon any of the recreation grounds, and in this way we manage to keep the grass growing on ground that would otherwise become bare. As soon as possible after the close of the football season our cricket pitches are renovated, well beaten and rolled, and, where necessary, relaid with new turf. If football has been allowed directly over cricket pitches, they usually require much renovating, but when taken in hand early in the "close" season, they can be made fit for play under ordinary conditions by the time cricket is permitted in the parks. The ground for practice has to be treated in exactly the same way as ordinary pitches, and, owing to the great amount of play which takes place upon them during the cricket season, they are invariably in a much worse condition than the match pitches. The attention which is bestowed upon these pitches incurs a considerable outlay each year, but, as previously stated in these notes, the extra expense involved is amply repaid by the increased facilities afforded the players.

An experiment.—This season we are trying an experiment in connection with the provision of cricket practice pitches, with a view to effecting economy. In the past we have had to re-turf the whole of our practice pitches each season, an expensive and, at this period of the year when so much other work is on hand, a very troublesome undertaking. In order to prevent this extra labour and expense, we are laying down lengths of cocoanut matting on well-rolled ground to take the place of turf. Cricketers all speak highly of this material for bowling upon, but whether from a financial standpoint it is to be preferred to turfing remains to be seen.

Presentation to Mr. D. CARSON.—On the 25th inst. the staff at Waterlow Park made a presentation of a marble clock, suitably engraved, and two bronze Marly statuettes, to Mr. D. Carson, on his promotion to a higher rank in the service of the London County Council. Regret was felt that Mr. Carson was leaving Waterlow, and good wishes were expressed for his success in the new position as superintendent of Southwark Park. In thanking the staff for the gift, Mr. Carson acknowledged the kindly feeling the members had shown him during the seven years he had been their superintendent.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

APPOINTMENTS FOR APRIL.

MONDAY, APRIL 1—Bank Holiday.

TUESDAY, APRIL 2—
Roy. Hort. Soc. Coms. meet.
Scottish Hort. Assoc. meet.
Nat. Amat. Gard. Assoc. meet.

THURSDAY, APRIL 4—
Roy. Hort. Soc. (Ireland) Spring Fl. Sh. (2 days).
Manchester & North of England Orchid Soc. meet.

FRIDAY, APRIL 5—
Truro Daffodil and Spring Fl. Sh.

SATURDAY, APRIL 6—
Soc. Franç. d'Hort. de Londres meet.
German Gard. Soc. meet.

TUESDAY, APRIL 9—
Devon Daffodil & Spring Fl. Sh. at Plymouth (2 days).
Brighton Spring Fl. Sh. (2 days).

WEDNESDAY, APRIL 10—
Liverpool Spring Fl. Sh. (2 days).

TUESDAY, APRIL 16—
Roy. Hort. Soc. Coms. meet.
Shropshire Hort. Soc. Spring Fl. Sh. at Shrewsbury.

THURSDAY, APRIL 18—
Linnean Soc. meet.
Manchester & North of England Orchid Soc. meet.
Huntingdon Daffodil Sh.

FRIDAY, APRIL 19—
Kent, Surrey & Sussex Daffodil and Spring Fl. Sh. at Tunbridge Wells.

SATURDAY, APRIL 20—
German Gard. Soc. meet.

TUESDAY, APRIL 23—
Midland Daffodil Soc. Exh., Birmingham Botanic Gardens (2 days).

WEDNESDAY, APRIL 24—
Roy. Bot. Soc. Exh.
Darlington Hort. Soc. Spring Fl. Sh.

TUESDAY, APRIL 30—
Roy. Hort. Soc. Coms. meet. and Nat. Auricula Soc. combined Sh. in R.H.S. Hall.
British Gard. Assoc. Ex. Council meet.

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich—45° 8'.

ACTUAL TEMPERATURES:—

LONDON.—Tuesday, March 26 (6 P.M.): Max. 58°; Min. 46°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—Wednesday, March 27 (10 A.M.): Bar., 30.4; Temp., 49°; Weather—Slight fog.

PROVINCES.—Tuesday, March 26 (6 P.M.): Max. 55°, N.E. Scotland; Min. 45°, Hull.

SALES FOR THE ENSUING WEEK.

WEDNESDAY—
Border Plants and Bulbs, Lilies, Azaleas, Palms and Plants, at 11; 4,000 Roses and Fruit Trees at 1.30 and 4; at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

FRIDAY—
Importation of *Odontoglossum crispum*, Imported *Cattleya Labiata autumnalis*; also established Orchids in variety, at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.45.

Tree

Topping.

Those responsible for the management of old trees in our parks, especially those in populous cities, and particularly when those trees are Elms, are placed in a serious dilemma. The Elms have in general attained maturity, have often become stag-headed and fungus-infected, and are, as is well known, liable to cast their branches suddenly and without warning, even when not diseased. Many deaths have occurred from this cause. What, then, is the best course to follow in such a case? To remove the Elms completely is to sacrifice the plans of the landscape gardener and to spoil the amenity of the park. To lop the trees, as is now being done, is to cause hideous disfigurement in the present and a thicket of brushwood in future, whilst it postpones,

rather than wholly averts, the dangers to which we have alluded. When a tree is removed there is always an outcry in the public Press, the writers in which do not seem to recognise that trees must decay and die like other creatures, but if a child be killed the outcry is justifiably still louder. To attempt to renew an avenue or a group by cutting out the old trees and planting new ones of the same species in the same situation is an unsatisfactory procedure. The best thing to be done is to form a new avenue elsewhere, and to wait, or be content with the notion that our successors will derive the advantage of our forethought, even as we have benefited by their proceedings.

It must be remembered that the lowermost limbs of the Elm are nearly of the same age as the stem, and consist chiefly of heartwood—a very brittle substance in this tree; and to shorten these, cutting back or removing many of the lateral shoots on them, so as to reduce the amount of leafage, is a prudent operation to adopt with aged trees, though, as we have said, it does not add to their beauty! We have rarely, if ever, known the limbs of other species of trees to fall with or without warning in calm weather in summer, except occasionally Oaks. Even other species of *Ulmus* than the common one, do not suffer in this manner, so far as we know. The topping of the Elms and other trees in Ravenscourt Park and Kensington Gardens is called for by the progressive decay producing "stagheadedness" of the highest branches. It is, we repeat, very questionable if the lopping can have any material effect in putting a stop to this malady, it being probably due to the roots having penetrated the beds of alluvial sand and gravel overlying the clay of the London basin, and being thus deprived of a sufficient supply of air. An alternative plan would be to fell the worst trees and those affected with fungus, and to plant others so as to complete the original contour of the group or avenue. As in the parks in question the original plan of straight-lined avenues has not been much interfered with by modern planters, clearances of old trees might, in spite of popular clamour, be carried out with good effect by planting vigorous young trees of some other species on the lines of the original plan, which in Kensington Gardens consists of radiating avenues converging on the round pond facing the Palace. But, as we have said, it is generally an unsatisfactory proceeding to attempt to "mend" an avenue. It is generally better to accept the situation, remove the old and dying trees, and make an avenue elsewhere. Felling is much more required than tree lopping and topping, so as to admit air and light into parts unduly choked with tree growth, and allow of freer development of those trees that are left.

A change of species of timber trees is also certainly desirable, just as in farming, for whereas a change of soil is an impossibility, the kind of crop grown can be easily changed with advantage. The Cornish Elm might be more largely planted; in the moister parts American and English Oaks might be employed more abundantly, these adding great beauty to woodland scenes in the autumn months; Maples, especially *Acer eriocarpum*, and Planes; Liquidambar; the green and the variegated-leaved Tulip trees; Mountain Ash, Robinia, *Sophora japonica*, *Alnus cordata*, the Ginkgo (*Salisburia*), Beech

and Hornbeam in variety if planted in hundreds—not singly—would in the course of time add much to the beauty and interest of the park. Limes and Thorns, however desirable in the country, are not to be recommended in towns.

The seventh report of the Woburn Experimental Fruit Farm, to be had from Eyre and Spottiswoode, is likely to be read with great interest by fruit-growers.

It will doubtless lead to considerable controversy and much difference of opinion. Of course circumstances alter cases, and much must depend on the point of view chosen by the disputant and upon the objects he has in view. The tree, left to itself, would no doubt resent the use of the pruning knife, and although the crop each year might probably be smaller in proportion and certainly the individual fruits smaller and less highly developed than in the case of the skilfully pruned tree, yet the life of the tree would be longer and it would be less liable to the attacks of canker and other fungi always ready to gain entrance through a wound. The object of the fruit-grower is somewhat different; it is not the health of the tree, he considers, but the abundance and especially the quality of the crop which are the first considerations with him.

At Woburn an attempt has been made to arrive at definite statistical conclusions as to the effect of pruning by measuring the leaves, and now by weighing trees of various kinds planted at the same time and in like conditions. The results are interesting, but it is obvious that the measurements and the weighings must be made of a vastly larger number of trees before errors can be eliminated or compensated and a fair average obtained. The results secured at Woburn (page 27) will hardly be accepted as being in accordance with general experience. "Where there is no pruning the crops are twice as great as when moderate pruning is adopted, and four times as great as when hard pruning is practised." Whilst fully believing that a great deal of unnecessary mutilation is practised, it is difficult to accept without considerable modification such a sweeping statement as that we have just quoted.

In Plate 1 two trees of Bramley's Seedling Apple are shown, one pruned, the other unpruned. This is rather unfortunate, as the variety selected is naturally a strong grower, and the hard pruned tree, though less in size, has much the thicker wood, and would probably be much the best tree in another ten years' time. The lesson would have been more valuable if the illustration had been taken from a weaker grower, such as Ribston Pippin or Margil, and there would be the danger of many unpruned trees becoming miserable specimens, such as shown on Plate 4, where Stirling Castle Apple is depicted.

However, the value of the report lies in the proof supplied of the importance of a judicious and moderate use of the knife. Few practical men will, however, agree with the statement on page 52: "That pruning not only does not increase the actual size of the tree, but it results in less new wood being formed." The experience of the majority is that pruning does increase the production of new wood, being the restoration of the balance between roots and top. In the case of a healthy, vigorous tree, properly manured, hard pruning is decidedly a mistake, and reduces the yield of fruit very materially. Facts and figures are given, as

GLADIOLUS "PEACE," A PURE WHITE VARIETY FROM AMERICA.

we have stated, showing the difference in favour of light pruning, and there is no doubt that in many gardens where severe pruning is carried out a study of the Woburn report would be useful. Cutting out branches which cross, or rub against each other, is pruning, which most people will consider a necessity. Any tree is the better for such attention, and the report advises the use of the knife for newly-planted trees and such trees as produce only fruit-buds. In brief, the report leads to the conclusion, on the one hand, that hard-pruning is wrong in the case of good, healthy trees, and, on the other, that no pruning at all is equally a mistake. The mean is obtained by a study of the requirements of each variety and the condition of the tree, and by acting accordingly.

OUR SUPPLEMENTARY ILLUSTRATION to the present issue depicts what is described as a pure white *Gladiolus* known under the name of "Peace," and it may be specially interesting to gardeners now that the season for planting *Gladiolus* corms has again arrived. It was raised by Mr. GROFF, Simcoe, Canada, and it is being cultivated for distribution by Mr. COWEE, of U.S.A. The variety is considered to possess exceptional merit, and has received certificates from the Society of American Florists and the Canadian Horticultural Association. Corms will be distributed this season, but we have no reason to think the variety is at present in cultivation in Britain. Messrs. KELWAY & SONS catalogue a variety under the same name, but that is described as of flesh-pink colour with violet spot and white tips, and, as Messrs. KELWAY have informed us, it was raised by themselves at Langport, Somersetshire. It is unfortunate that two new varieties should bear the same name. For the photograph we are indebted to Mr. A. DIMMOCK.

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the committee will be on April 2, in the afternoon at 3 o'clock. A lecture on "Orchid Hybrids," illustrated with lantern slides, will be delivered by Mr. H. J. CHAPMAN.

THE WORKMEN'S COMPENSATION ACT.—To what extent an employer of gardeners, garden-labourers, and casual assistants is liable in the case of injury or disablement to the employee under the Act which comes into operation on July 1 next is not altogether clear. Some idea may, however, be gained from the *People's Guide to the Workmen's Compensation Act*, which may be had for a penny from Messrs. BEMROSE & SON, 4, Snow Hill, E.C.

DEPARTMENTAL COMMITTEE ON AGRICULTURE.—The President of the Board of Agriculture and Fisheries has appointed a departmental committee to enquire as to the provision which has now been made for affording scientific and technical instruction in agriculture in England and Wales and to report whether, in view of the practical results which have already been obtained, the existing facilities for the purpose are satisfactory and sufficient, and, if not, in what manner they may with advantage be modified or extended. The members of the committee are as follow: The Right Hon. LORD REAY, G.C.S.I., G.C.I.E. (Chairman); LORD BARNARD; LORD MORETON; Mr. FRANCIS DYKE ACLAND, M.P.; Mr. DAVID DAVIES, M.P.; Mr. NORMAN LAMONT, M.P.; Mr. THOMAS LATHAM; Mr. JOHN CHARLES MEDD; Professor THOMAS HUDSON MIDDLETON, M.A., M.Sc., one of the assistant secretaries of the Board of Agriculture and Fisheries; Professor WILLIAM SOMERVILLE, D.Sc.; and Mr. HENRY STAVELEY-HILL, M.P. Mr. ARTHUR ERNEST BROOKE-HUNT (Board of Agriculture and

Fisheries) will act as secretary, and Mr. HENRY LEON FRENCH (Board of Agriculture and Fisheries), as assistant secretary to the committee.

THE LATE SIR THOMAS HANBURY.—The remains of this eminent philanthropist were, we learn, cremated at San Remo. The Syndic of Ventimiglia gave expression to the sorrow of the neighbours and to the gratitude and veneration they felt for their benefactor. Thousands lined the streets of Ventimiglia, and at Bordighera and San Remo the inhabitants also manifested their sympathy. The Italian Minister for Foreign Affairs, the Universities of Rome and Genoa, besides many mayors and heads of public institutions, sent telegrams of condolence. The memorial service at Mentone, to which we have already alluded, was held in the French Protestant church which Sir THOMAS was in the habit of attending. The Pastor and the Mayor expressed the sympathy of the inhabitants of Mentone with the family.

CROCUSES AT HAMPTON COURT.—The town-dweller or suburban resident accustomed to grow a few bulbs in small gardens or back yards, or in pots or pans, has but a poor estimate of the wondrous beauty bulbs can produce in the early spring when planted somewhat naturally on a large scale. Even at Hampton Court, where bulbs play a prominent part in the spring bedding, the display obtained seems stiff and formal, compared with what is seen when more natural conditions are copied. Thus, just recently the Crocuses planted in the grass beneath the tall Lime trees, and in area running into acres, have been beautiful beyond description. Literally the wealth of beauty furnished, and yet all provided just as though nature alone had done it, might be regarded as giving a glimpse of fairyland. To copy nature without formality is the chief art of the gardener, but all the same it needs the eye of a true artist thus to reproduce natural beauty.

BRITISH GARDENERS' ASSOCIATION.—A meeting of the council of this association was held at the R.H.S. Hall, Westminster, on March 19, Mr. W. H. DIVERS presiding. Twenty-two new members and one apprentice were elected, bringing the total number elected up to 1,088. On the report of the sub-committee it was decided to defer for the present the question of registering the association. Attention was called to the action of the Cardiff City Council in recognising the certificate of the association as a mark of distinction amongst gardeners, and it was hoped that other public bodies will follow the lead given by Cardiff. A publication committee was appointed to commence the publication of a quarterly journal, the committee consisting of Messrs. C. H. CURTIS, C. FOSTER, E. F. HAWES (treasurer), R. HOOPER PEARSON (vice-chairman), and J. WEATHERS (hon. secretary). At the annual meeting of the association, to be held on May 29, papers will be read as follows: "Testimonials," by Mr. A. C. BARTLETT; "Apprentices," by Mr. DALLIMORE, of Kew; and "Examinations for Gardeners," by Mr. C. FOSTER, Reading.

DEATH OF PROFESSOR WARINGTON.—It is with sincere regret that we had briefly to record in our last issue the death of Professor ROBERT WARINGTON, who expired on Wednesday, March 20, at his residence, High Bank, Harpenden, at the age of 69 years. We can now add some particulars of his career. The deceased had always been an active man, and the beginning of his health failure was about twelve months ago, when he underwent an operation for an internal disorder, an operation which greatly benefited him for a time, but eventually a recurrence of the malady gradually led to his death. Mr. WARINGTON was a son of the chemist to the Society of Apothecaries, and was well known among noted agricultural

chemists. He was a Fellow of the Royal Society and of the Chemical Society. He worked in the Rothamsted Laboratory for some time in 1859, afterwards taking a position at Cirencester Agricultural College. In 1867 he became chemist to Sir John Lawes' manure and tartaric and citric acid factories, returning to the Rothamsted Laboratory in 1876 and remaining there until 1890. His special work at Rothamsted comprised the systematic analysis of rain, drainage and well-waters; the determination of nitrates, chlorides, and carbon in soils; a prolonged investigation of the process of nitrification; and a study of the chemical action of various micro-organisms. For three years he held the post of Sibthorpe Professor of Rural Economy at Oxford. Professor WARINGTON is probably best known for his popular text-book, *The Chemistry of the Farm*, No. 1 of the series of *Morton's Handbooks of the Farm*, which has passed through 15 editions. He was an occasional contributor to this journal; also to most of the leading agricultural and chemical journals of the country. In 1891 he visited America for the purpose of delivering a course of lectures on the investigations at Rothamsted, under the provisions of the Lawes Agricultural Trust. Mr. WARINGTON was twice married. His second wife, a daughter of the late Dr. F. R. SPACKMAN, of Harpenden, remains to mourn his loss; there are five children. The funeral took place at the Parish Church, Harpenden, on the 23rd inst.

OOTHECA WOLLEYANA.—We have referred, on more than one previous occasion, to this "illustrated catalogue of the collection of birds' eggs formed by the late JOHN WOLLEY," so need merely mention the appearance of a new volume, edited by Professor ALFRED NEWTON. This is the fourth and final part (*Alcae-Anseres*) and contains a supplement and appendix as well as Prof. NEWTON's retrospect and farewell to his readers and to his labour of love. This handsome and most important book is published by R. H. PORTER, 7, Prince's Street, Cavendish Square, and is indispensable to students of birds and their eggs.

ANGLO-AMERICAN GARDENERS.—To add to the list recently given we may cite these names:—

J. M. HUNTER, the President of the National Association of Gardeners, who began his gardening career under ROBERT DRAPER, of Seaham. Mr. HUNTER made his mark in landscape work here, and has emphasised it in the United States.

MR. JOHN SHORE is an Irishman who passed through the nurseries of DOWNIE, LAIRD & LANG, and of METHVENS, of Edinburgh. After various experiences in England he went to America, and is now Vice-President of the National Association of Gardeners.

JOHN WHALLEY, the Treasurer of the same society, was born in Manchester, but went to America when he was 18 years old.

JAMES BELL was born at Ecclefechan and went to America in 1894, and has filled many important positions in that country.

CHARLES DUMPER was an apprentice at Glen Eyre, Southampton, and held many important posts in this country before he migrated to the States.

THOMAS H. WHITE was born in Gloucestershire, where he worked with his father in several gardens. The whole family crossed the Atlantic, and the son is now gardener at the Maryland Agricultural Experiment Station.

MR. JAMES M. LOGAN was trained at Castle Semple, Renfrewshire, migrated to Canada, and thence passed to the States.

DAVID DOUGLAS (auspicious name!) was born at Ayr in 1831, and in his 21st year went to Connecticut, and latterly was Superintendent of the Gardens at Vanderbilt University.

M. SORENTON is a Dane by birth, but passed some time in the nurseries of Messrs. Low & Co., of Clapton, and of Messrs. ROCHFORD, of Cheshunt.

Portraits of these gentlemen were given in our namesake, the *Gardeners' Chronicle of America*.

FLOWERS IN SEASON.—From Messrs. CLIBRANS, Altrincham, Cheshire, we have received flowers of a good strain of *Cinerarias* of the ordinary florists' type.

LORD GROSVENOR AND MANX CODLING APPLES.—We learn from various sources that these two valuable culinary Apples are much sought after in Germany, especially in the Rhine provinces, the former more especially, on account of its extraordinarily abundant bearing. As it suffers in some parts from the attacks of *Fusicladium dendriticum*, it is considered good practice to spray the trees once or twice annually with the Bordeaux mixture. Notwithstanding the heavy and early cropping of the bushes and standard trees of Lord Grosvenor, these do not become stunted or crippled in their growth as is the case with others of the Codlin class. In the opinion of cultivators in that country this variety is to be preferred for early bearing and fruitfulness to Charlamowsky, Spice Apple, and others. Nurserymen on this side of the water should not lose sight of the increased demand in Germany for Lord Grosvenor and Manx Codling.

POTATOS.—The Hon. H. A. STANHOPE has compiled an interesting pamphlet on the history and development of the Potato from the date of its introduction to Europe to the present time. It is somewhat singular that the original water-colour drawing of the plant by CLUSIUS, still preserved at Antwerp, and reproduced in our columns, should not have been mentioned. But 26 pages, which is all that the "One and All Series" of pamphlets can afford to allot to the subject, are obviously insufficient to allow of "excursions" into history, or even diseases. The main object, that of giving an account of the cultivation of the tuber, is well fulfilled. The author has his gird at the "compound titles too common with scientific men, which, being partly Greek and partly Latin, are not fully intelligible in either language." It may be pointed out that it was quite unnecessary in a popular treatise of this kind to use the technical name of the Potato fungus at all, but that if it were used, the author should have taken care to spell the name correctly. For ordinary purposes everyone understands what the Potato disease is, in spite of the fact that the maladies incident to the tuber are many. If we say the Potato disease or the "late blight," we need not offend the susceptibilities of those who object to the words of Greek or Latin derivation.

FLOWERS AND THE PHYLLOXERA REGULATIONS.—We have repeatedly pointed out in this journal the uselessness of most of the regulations of the various European States against the importation of this pest of the vine into their territories, the hindrances to the nursery trade and the personal annoyance of which they are the cause. The latest case, of which a brief statement appears in the number of the *Binderkunst* for March 1 now before us, exhibits the Austrian regulations against the introduction of Phylloxera in a most ridiculous light, and bears repeating in the English language. The writer of the note in the journal named states that he was desirous of affording a pleasant surprise to his bride on her birthday by taking a basket of flowers. The lady resided in Bohemia, and he had to journey right across Germany, carrying his basket of flowers, as he would an uncooked egg, and arrived at Bodenbach, the end of his journey. On being asked by the Austrian official of what the contents of the basket consisted, he said living (fresh) flowers. "They cannot pass the frontier because of the Phylloxera regulations, or only with the permission of the Austrian Foreign Office," said the official. I might send a telegram to Vienna, and then it might be allowed. I declined to adopt this way out of the difficulty, and the drama began

to assume a tragi-comic aspect. I declined to throw the flowers away, and I requested the official to accept them as a present for his sweetheart, and naturally this offer was gruffly refused. "Well, then," said the traveller, "throw the basket, flowers, and all into the Elbe." "Must not occur on Austrian soil, and they must therefore be transported to Saxony." In short, it was necessary to place the tender spring blossoms under lock and bolt of the Austrian Custom House till the next day to be fetched by a carrier, and find an early grave on German soil.

COMMONS AND FOOTPATHS PRESERVATION SOCIETY.—Lord EVERSLEY presided recently over the monthly meeting of the executive committee of this society, held at 25, Victoria Street, S.W. It was stated that eighteen railway, water, and improvement Bills introduced into Parliament during the current session affected 787 acres of common land or open spaces, and the solicitor (Mr. P. Birkett) reported that several promoters had already agreed to insert clauses for the protection of the public interests in consequence of the society's intervention. The London and North-Western Railway Bill had been blocked by Sir John Brunner on behalf of the society owing to the serious nature of its proposals with regard to Gosford Green and Stoke Heath, Coventry. A satisfactory settlement had now been arrived at by which the commons would be preserved. The Metropolitan Water Board had also agreed to the insertion of a clause in their Bill to provide that the powers sought by the Board over Streatham and Mitcham commons, and Wyke, Plough and Mitcham greens, should be limited to the acquisition of easements only, and that all conduits should be laid underground when crossing the commons. It was further reported that the Board of Agriculture had raised technical difficulties to the application of the Witley Parish Council to enclose a portion of Milford Common, Surrey, for the purpose of a burial ground, and that in consequence of these objections it was understood that the proposal would be abandoned. It was resolved to reintroduce into the House of Commons the society's Rights of Way Bill, which passed its second reading last session, and also to introduce a Bill to facilitate the regulation of rural commons and the restriction of the powers of highway authorities to disfigure commons in searching for road metal. The solicitor stated that the society's scheme for the preservation of Towyn Trewan Common, Anglesey, had now been approved by local parish meetings. The common comprised 1,300 acres of pasture land and sandhills bordering the sea shore at Rhosneigr, and it was proposed to acquire 600 acres of the land and regulate the whole area as an open space. The total amount needed to enable this to be done was only £1,300, and the society resolved to issue a public appeal for that sum, in view of the importance of permanently preserving the largest common in Anglesey.

HOW I WORK MY SMALL FARM.—By F. E. GREEN. This should prove a handy book to the many who wish to manage a small farm. It is an account of the writer's actual experience in farming on sixteen acres, so successful on the whole that he is justified in encouraging others to follow his example. But he warns the oversanguine that the work is neither poetical nor simple; "one has to be a bit of a carpenter, a bit of a carman, a bit of an engineer, a bit of a bricklayer, a bit of a biologist, botanist, and veterinary surgeon, as well as a bit of a weather prophet. You must know something of woodcraft; how to handle a bill-hook, and fagging-hook; how to swing a scythe, and split rods for thatching. Above these useful technical accom-

plishments you must learn the necessary but hideous art of driving a bargain." We commend Mr. GREEN'S chapters on fruit and vegetable growing for market to the attention of those who contemplate undertaking such enterprises. Specially do we desire to call the attention of our statesmen and economists to the chapters relating to "Small Holdings and the State," and co-operative small holdings: "The bane of country-life is its extreme individualism. The lack of collective effort, and the absence of guilds has left these country craftsmen in a state of depressing poverty. The cottages they live in are very often hovels in which no country gentleman would think of housing his horses or his dogs, and yet they are considered good enough in which to breed our Imperial race—the decadent descendants of what was once a race of yeomen." The publisher is A. C. FIFIELD, 44, Fleet Street.

RETARDING PLANTS.—There is no doubt also that a cool atmosphere is a great aid to prolonging the life of cut blooms, and in this way refrigeration comes to the aid of the florist. I recently designed some cooling chambers for a large West-end florist, and I am given to understand that in the summer great benefit is derived from keeping the cut blooms in a temperature of 45° during the night, and until they are wanted in the shop for sale. It is, however, to the horticulturist that refrigeration has come as the greatest surprise and assistance. In the past, plant life has been retarded or advanced by the absence or presence of light and heat, and, by means of artificial heat, both fruit and flowers have been produced out of due season. This out-of-season production has, if possible, been brought to a greater state of perfection by the antithesis of this arrangement, or by the retardation of the development of life by placing the roots in a cold temperature. The principle is fairly obvious: all living things require a period of rest. In the vegetable kingdom, with a few exceptions, this rest is taken in the winter, while the work is done in the summer. In a cold store it is always winter, and so long as the life of the plant is not retarded to the point of extinction, its generation of new life can be kept back almost indefinitely. With this knowledge, and the proper facilities for making use of it, at his disposal, the gardener of the day becomes practically master of the situation, and can make plants and flowers bloom or fruit just as and when he pleases. In fact, it is quite possible to-day to give an order to a horticulturist for a thousand Lily of the Valley blooms to be delivered at your residence on the 20th of June, July, or August next, or in fact any other date, and to pass the interval of time in perfect security that the order will be duly fulfilled. There appears to be no reason why practically any root plant should not be capable of having its growth retarded by cold storage. Its use is at present confined to retarding varieties of bulbs, but any perennial should be, within limits, susceptible to the same treatment. The method employed with Lilies of the Valley is as follows:—The roots are taken straight out of the cold store, and after they have been thawed in the ordinary atmosphere, are planted out under glass in beds or pots in the ordinary way. Lily of the Valley crowns which have not been artificially retarded take six weeks in which to flower. Retarded roots are much more vigorous. The influence of warmth and dampness rapidly stimulates the dormant vitality. In a few days they begin to shoot, in a week the plants are growing strongly, and in less than a month they are in full bloom. It is a curious thing that the prolonged rest appears to have the effect of making the growth exceedingly rapid, once it is started. Hal Williams, in *Journal of the Society of Arts*

CYCLAMEN LATIFOLIUM.

Has *Cyclamen latifolium* been improved by the florist? To this question there is undoubtedly more than one answer. A keen florist who has great admiration for size would say no doubt that the improvement has been enormous, but from the point of view of grace, elegance and prettiness, I think that the original is much the best. Mr. Peter Barr very kindly sent me some bulbs from the wild form of this *Cyclamen* which are now in flower in the Cambridge Botanic Garden and they are most charming, flowers are numerous and graceful, and the leaves are prettily marbled. In comparison, the improved *Cyclamen* may be described as heavy, few-flowered, ungainly and lumpy, while the leaves are awkwardly fleshy and without the same perfection of marbled surface. *R. Irwin Lynch, March 14, 1907.*

FIG. 92.—CYCLAMEN LATIFOLIUM AS GROWN AT CAMBRIDGE FROM "WILD" CORMS FURNISHED BY MR. PETER BARR.

THE PROPAGATOR.

MANY species of plants produce "runners" on the surface of the soil which are capable of taking root, and in that manner increase the circumference of the mother plant. This mode of increase or reproduction is in some instances taken advantage of by the gardener, as, for example, in Brambles of all kinds, *Syringa*, *Bambusa*, &c., which are taken off at the right time from the parent plant and planted in suitable soil and favourable situation. For most of such runner-producers the spring affords the most suitable season.

Other plants, on the contrary, make underground shoots and suckers, which almost have the form of roots. These, if cut into pieces, and laid in pots, pans, or the soil out of doors, and covered with sandy soil, soon emit shoots and roots, and when the latter are well developed, the pieces may be taken up carefully, and either potted or planted out. Such are *Curculigo*, *Anemones* of the Alpine section, which are also readily increased by division in the present month, and *A. japonica* and its varieties. Plants of *Colocasia antiquorum*, *nymphæifolia*, *esculenta*, and others; and *Alocasia Lowii*, *tigrina*, *Veitchi*, *macrorhiza*, *Dracæna*, &c., develop underground shoots, whose points sometimes take the form of tubers. It is merely necessary for propagating purposes to remove

these from the mother plant with a knife, and insert them in a sand bed or small pots, like any other sort of bulb or tuber. Development is very quick, and a handsome plant is soon obtained. *Dichorisandra*, *Calathea*, *Maranta*, *Phrynium variegatum*, and *Cannas* are readily increased by means of underground tuberous rhizomes, which, removed from the mother plants, laid in suitable soil, and afforded sufficient water and warmth, reproduce the plants with certainty—some of the rhizomes in 8-10 months, and a few in from 15-18 months.

DAHLIA, CLEMATIS, AND TREE PÆONIES.

March and April are the best months in which to graft the shoots of the desired varieties on to the tubers of others. The newly-sprouted growths are removed from the tubers of some poor varieties, and the shoots of the superior varieties, each furnished with a good basal bud are inserted as

roots of the same dimensions as the graft are available, whip grafting may be adopted. Great care must be taken to secure healthy roots for the stocks, not to wound or otherwise injure them, and to work quickly, so as not to exhaust the roots by exposure to the air.

At this season out-of-doors subjects may be similarly increased, with the proviso that leafless shoots are taken for the scions. The roots at the lower end of the stock have only one purpose, viz., to feed the scion until it has made its own roots.

BIGNONIACEÆ.

The climbing species may be raised from cuttings in almost every instance, but those with erect stems, firm wood, and leathery leaves are difficult, and require more care. For such species as *B. stans*, *B. fulva*, almost evergreen, the present month is the best for striking cuttings; but of such as lose their leaves in the winter season, the cuttings should be taken from well-developed spring shoots having three to five pairs of buds, the lowest pair being of the previous year. A suitable soil consists of leaf-mould two parts, good loam one part, sand one part; the cutting pots should be afforded good drainage, and above it should be placed a layer of the soil $1\frac{1}{2}$ inches thick, and above that some clean silver sand.

The cuttings should receive a moderate quantity of water, and be covered with a bell glass. The climbing species require for a satisfactory rooting of the cuttings a bottom heat of 70°-75° Fahr., and those with leathery leaves of 80°-70°.

DAPHNES, &C.

In this month *Daphne indica* and its varieties may be grafted on established stocks of *D. laureola*, placing them in a warm case or frame.

Hydrangeas may be increased for flowering next year by taking young flowerless shoots of the present year, and inserting them singly or a few together in small pots filled with sandy loam and leaf-mould, placing the pots in a bottom-heat bed of 75°-80°. Rooting soon takes, when the plants should be gradually inured to greenhouse conditions. *F. M.*

THE MOHWA TREE
(BASSIA LATIFOLIA).

THIS tree, which is fortunately so common throughout large areas of the Bhil country in Western India, is a perfect mine of wealth. The flowers provide a very large proportion of the Bhil's food supply. They are eaten fresh, dried, and also cooked with parched grain. In the spring, when the buds appear, whole families temporarily migrate to the jungles for the "Mohwa harvest." The ground round the tree is carefully cleared, and as the flowers fall, they are collected and stored. When dried, they are sold in the bazaar for the liquor trade, and it is from these that practically the whole of the native liquor consumed in Central and Western India is distilled. In times of scarcity, the monetary value of the Mohwa flower rises with the intensity of the distress, and it often becomes of vital importance.

The Mohwa seed contains a valuable oil, which is used locally for cooking, for burning, and medicinally for application in cases of skin disease. A large quantity is exported annually to France, and doubtless contributes considerably to the world's supply of olive oil; it is ostensibly intended for the manufacture of soap. Further, a white milky juice is obtained from cracks in the bark, and the bark itself is often utilised for dyeing purposes, while the flowers, in the form of a decoction, provide a medicine largely used and much appreciated as a stimulant, an astringent, and even as a cough mixture.

The Mohwa tree is regarded as sacred by the Bhils, and it is almost the only tree of the forest that they will not either cut or destroy. It is jealously guarded as the personal property of the holder of the land in its neighbourhood, and it is only in the depths of the forests that the first-comer has the right to sit down under the tree and collect the crop. *Captain Barnes, in Journal of Society of Arts, February 6.*

SWEET PEAS OF RECENT INTRODUCTION.

THE Sweet Pea possesses exquisite colour, beauty of form, perfect hardness of constitution, and delicious fragrance. It is truly a flower of light and sweetness, and should be found in every garden that is worthy of the name. Shortly before his death, Mr. Henry Eckford gave to the world several varieties of the highest distinction, which should be sufficient of themselves to immortalise his name. Supreme among these is Dorothy Eckford, undoubtedly the largest and loveliest pure white Sweet Pea in cultivation, which, though not hooded like its immediate predecessor, Sadie Burpee, surpasses it in purity and dimensions.

last year, did not seem to me to be quite so luminous in colour as the Scarlet Gem. Queen Alexandra is, however, unquestionably very effective—I should call it the brightest of crimson-scarlet varieties—and it has this somewhat important recommendation, that it does not burn in the sun. My own beautiful Eckfordian namesake, parma-violet in colour, with purple shading, has proved popular beyond my utmost anticipations, and Mr. John S. Eckford tells me in a recent letter that there is hardly a foreign country to which he has not sent it, including China and Japan.

Of the many exquisite varieties derived from Countess Spencer, which has proved itself a veritable mother of sports, three of the finest

former being white, marbled with blue (native of California), Horace Wright, whose distinctive colour is deepest violet-blue; Mrs. Alfred Watkins, a great improvement on Princess Beatrice; Earl Cromer, E. J. Castle (brightest rose), Frank Dolby, which has affinities in point of colour with Lady Grizel Hamilton; Agnes Eckford, of delicate pink complexion and faultless formation, and its beautiful contemporary, the Queen of Spain. *David R. Williamson.*

A LARGE CAMELLIA TREE OUT OF DOORS.

THE plant illustrated at fig. 93 measures 6 feet in circumference, 11 feet 6 inches in height.

FIG. 93.—LARGE CAMELLIA BUSH IN THE OPEN AIR AT LEONARDSLEE, SUSSEX.

Henry Eckford, while somewhat disappointing to exacting cultivators, is perhaps the nearest approach to a pure orange colour that has yet been introduced. To give this special variety full scope for the display of its possibilities of growth, it should be thinly sown—an injunction of the raiser too frequently ignored.

The Scarlet Gem, when introduced by Mr. Eckford, made a veritable sensation, and though it is not, when compared with some others, a very vigorous grower, being somewhat too susceptible to atmospheric influences, ought to be grown in a half-shady situation. It is, in my opinion, a nearer approximation to a true scarlet variety than Queen Alexandra, which, in my own garden, where I had it in bloom for the first time

examples are Helen Lewis, Gladys Unwin, and Nora Unwin, of which the last-named may be characterised as a pure white Countess, and is one of the loveliest of recent introductions. Its great charm lies in its having the standard and wings beautifully "crenulated," or "waved." I sometimes think that if it should prove prolific and a vigorous grower, it may eventually supersede even Dorothy Eckford.

An improved Queen Victoria has been found in Mrs. Collier, an eminently graceful flower of great substance and durability, which some cultivators have described as the finest Sweet Pea of pale primrose colour that has hitherto appeared. Other recent and interesting introductions are Helen Pierce and Shasta, the

and in a season is calculated to produce 5,000 to 6,000 double pink flowers. Last year (1906) open flowers were continuous from January 5 till May 15. It has just been dressed with several loads of cow manure and about 20lb. of bone meal, and the foliage is now beautiful. Plenty of nourishment and water are necessary at this stage. In the summer the hose is let run on its roots for several hours at a time. A good top dressing of soot several times a year is also helpful in maintaining the foliage a beautiful dark green colour. This is the handsomest of many Camellias that abound in these gardens. As an evergreen it is well worth its place. *W. A. Cook (gardener to Sir Edmund G. Loder, Bart.), Leonardslee Gardens, Horsham.*

TREES AND SHRUBS.

THE FERTILISATION OF ARAUCARIA IMBRICATA.

In the chapter on *Araucaria imbricata* in Mr. Elwes' *Trees of Great Britain* the paragraph dealing with cones states that "the cones take two years to ripen, fertilisation occurring in the second year, in June or July, when the scales open and expose the ovule to the pollen blown from neighbouring trees." I know that some transatlantic botanists are (or were) of the opinion that "pollination" takes place in the first year, but that the pollen remains in the cone-flower until the next spring, when it passes down the micropyle, and then "fertilises" the ovule. But I have not previously met with the theory that the cone-flowers are directly fertilised with outside pollen in their second year. I am not a botanist, but, being in charge of one of the finest collections of Conifers in our islands, and one which contains an unusually large number of adult *Araucaria imbricata*, I have had exceptional opportunities of observing the behaviour of these trees, and I am of the opinion that Dr. Henry's theory is incorrect. The formation of cone-flowers one year to be fertilised the next seems purposeless, and Nature rarely does things in that manner. Dr. Henry, in the work mentioned, says, "the male flowers frequently remain intact on the tree for several years: in Europe they generally appear early in spring." I have rarely known the male flowers remain on the trees longer than a year. Already many of those which shed their pollen last July have fallen, and in the southern counties of England the male flower-buds first appear late in autumn, and by the end of November they are readily seen. The cone-flowers usually make their first appearance towards the end of April: they are then globular tufts of narrow leaves paler in colour than the true leaves. These buds grow rapidly, and by the time—at about the end of June, according to the season—the pollen is liberated from the catkins are about 7½ inches around. They increase in size until, roughly, the middle of November, when a cone tightly measured is 11 to 12 inches around. From this period the cones make little or no increase until about the beginning of April, when growth is again resumed. By the time next year's pollen is ripe (some years not till the second week in July) this year's cones will be nearly fully grown, for the ripe seeds frequently fall in August, leaving the woody axis on the branch. Last summer I artificially fertilised, or I had better say pollinated, a number of cone-flowers, and I send a section of one to show the present development. A. C. Bartlett, *Pencarrow Gardens, Cornwall*. [The section was forwarded to Prof. F. Oliver.—Ed.]

TORREYA CALIFORNICA.

In connection with the notes on this tree on page 99, it may be of interest to record a fine specimen growing at Coldrenick, the Cornish seat of General Jago Trelawny, near Liskeard, which is over 35 feet high and well furnished with healthy foliage. It is broadly-pyramidal in habit, much like a typical *Abies bracteata*; in fact, as I first saw it at a little distance, its habit, and nearly horizontal branches, deceived me into thinking it was an example of the "Santa Lucia Fir," but a closer examination established its identity. Examples of the Californian nutmegs seem to be very rare in this country, and they do not seem to be in favour with planters, but where room can be afforded, these trees should be represented, if only as curiosities. They are reputed to be tender, and also slow-growing in a young state. I fancy the character for tenderness is undeserved, and owes its origin to trees having been over-nursed. The Coldrenick specimen, although planted nearly

half-a-century, gives no promise of ever reaching the dimensions quoted in the *Gardeners' Chronicle* (100 feet), but is quite large enough to give pleasure as an ornamental tree, and is perfectly healthy. It is growing on very high ground, in well-drained loam of moderate quality, and only lightly screened from wind. As it seemed to me that these conditions most probably contributed to its success, I soon afterwards obtained Mrs. Ford's ready approval to plant young trees of this species, and also *Torreya nucifera* in a similar position at Pencarrow. It is, of course, too soon to speak of these trees, but even if they do prove to be "slow growing in a young state," their ultimate success is worth any initial disappointment. A. C. Bartlett.

PHOTINIA SERRULATA.

This tree, I believe, was introduced from China and Japan in 1804, and is not supposed to be of a very hardy nature, it having been cut to the ground by the frost in 1860, since which date very little harm has happened in these gardens to the fine plant, which measures 22 feet in height and 23 feet in diameter. This is supposed to be the finest in the country. It has Laurel-like leaves, about 5 inches long, and these when in a young state are of a beautiful bronzy chocolate colour. The flowers are small and produced similarly to those of the *Laurus tinus*, a spray of which was exhibited at the Royal Horticultural Society's meeting of February 12. This fine specimen is not growing against a wall.

LIRIODENDRON TULIPIFERA.

There is a fine Tulip tree here, whose height is 93 feet, girth 4 feet from the ground 11 feet 10 inches, and at the base 17 feet. This tree has a clean stem of nearly 30 feet before there are any branches. W. A. Cook, *Leonardslee Gardens, Hersham*.

NOTICES OF BOOKS.

DR. SORAUER'S HANDBUCH DER PFLANZEN-KRANKHEITEN. Parts 1 to 10—Diseases of Plants.

Since our first general notice of this publication, we have received ten parts of the work. As we stated before, Prof. Sorauer's book is published in parts, and it is expected to be completed in 16 to 18 parts. The whole matter is arranged in three volumes. The first one deals with diseases or injuries to plants which are caused by unsuitable culture, unfavourable weather, smoke, gases, or any physical or mechanical cause. The second volume, prepared by Prof. Lindau, of Berlin University, deals with the diseases of plants caused by fungi, and the last volume contains the entomological portion.

The first volume is much in advance of the others in publication, and enables the reader to form a good opinion as to the practical value of the work, which is based mainly on scientific research and practical experience. Altogether, Dr. Sorauer deserves the credit of bringing before the public a work exhaustive in its treatment of this subject, and written in plain, everyday language, thus being equally valuable to the practical man and to the student. Prof. Sorauer believes in what he terms a "predisposition" of plants to parasitic diseases. The term is, however, not well chosen, and conveys little meaning to the English reader; we would prefer to speak of the conditions which render a plant more or less susceptible to disease. It often happens that though one may notice that a particular crop shows distinct signs of disease, on examination none of the common agents—fungi or insects—can be recognised as causing the malady. The first volume deals especially with these injuries. The difficulty experienced in cultivating plants out of their proper regions is well known, and the "injuries," or, rather, de-

fective growth, find their explanation in practical experiments. The same may be said of plants growing on steep inclines, or too deeply planted, so that atmospheric conditions and an ill-regulated water-supply produce deviations from health. Similar injuries result from the cultivation inland of plants which thrive only on the coast and *vice versa*.

The second chapter deals with the physical conditions of the soil, and it is interesting to find that to this source is mainly attributed the dwarf growth of the well-known Japanese miniature plants. It is the duty of science to destroy sentimental superstitions, and to throw light on misleading mysteries, even if it is only the case of the Japanese dwarf-tree mystery. Some plants of this kind were subjected to examination, and it was found that only 30 "yearly" rings could be counted. Prof. Sorauer says that by means of clever cultivation, or, rather, by systematic starvation, trees may be artificially dwarfed in less than the time generally stated. It is well to have this interesting information, though it may seem like giving away a "trade secret"!

In the same chapter we find accounts of impaired health consequent on unsuitable condition of the soil (e.g., light, sandy soils), or due to the presence of underground water, as well as of the diseased condition of the trees which line the streets of cities. In horticulture we often meet with cases of ill-health in plants grown in pots, due to "unsuitable conditions of the soil." What a badly-drained field is to a farmer a badly-drained flower-pot is to the gardener. The drainage crocks cease to be of use, and the soil becomes sour when careless watering is practised. The top-soil becomes covered with a whitish-yellow crust, and the pots themselves appear as if mouldy. These incrustations consist mainly of carbonate of lime. When these signs appear the gardener may be assured that stagnation has set in. We find in this chapter, which is a very lengthy one, careful explanations of many maladies which are well-known both to farmers and to gardeners, but the cause of which has been hitherto little studied; and what is more of importance still, the causes to which these maladies are said to be due have been established by exhaustive experiments. We may here just briefly refer to a few cases which are well known, though very little attention has been paid to the remedial measures. Thus the author explains the injuries to Cherry and Apple trees growing in unsuitable soil. The injury is often noticeable, and manifests itself in small fissure-like, scabby patches on the roots and shoots of the trees. Similar injuries on Sweet Chestnuts and Copper Beeches and on Sugar Beet and Mangels are explained. All these injuries may be remedied by efficient drainage and top-soil ploughing, and by the influence of frost on the fields after ploughing.

The next chapter is an important one for the agricultural and horticultural chemist. In it are investigated the injuries due on the one hand to the absence or to the superabundance of certain chemical constituents, and on the other hand either to drought or to the superabundance of moisture. Numerous cases of the well-known malformations, fasciations, proliferous growth and other teratological phenomena are explained in this chapter.

The second division of the first volume begins in the last part issued, and deals mainly with noxious atmospheric conditions which destroy or injure vegetation. The opening chapter deals with injuries caused by a dry atmosphere, especially those to buds, the defoliation of trees, the common honeydew of Poplars, Limes and other trees.

Some injuries, like dry rot of Mangels; the dropping of flowers, and the failure of plants cultivated in rooms—none the less important because so common—are investigated. At the close of this chapter we find mention of the hard-coated seeds of leguminous plants which are also due to the dry atmosphere of hot summers.

In contrast to the last chapter, the next one deals with superabundant atmospheric moisture, and the injuries caused thereby to Potatoes, Vines, &c., are investigated. The well-known "intumescences," i.e., small, whitish outgrowths from the surface of the leaves or leaf-ribs, are explained as being mainly due to this cause. One of the commonest intumescences occurs on the pods of Peas, appearing like a whitish scab on the exterior of the pods, which can be easily removed. This concludes the first volume so far as published. We expect to see in the next issues a discussion of the influence of gases and smoke, and are anticipating a careful investigation of the very common injuries caused by these agents.

The parts reviewed have excellent illustrations which help to easily explain the injuries dealt with in the text.

SECOND VOLUME.

Beginning with the injuries caused by the lowest forms of plant life, this volume opens with a thorough exposition of the plant diseases caused by bacteria. Cases of injury resulting from infection by various forms of these minute organisms are by no means rare; we meet with a number of them in our farms and gardens. Bacterial diseases of Potatoes, Tomatoes, Cucumbers, the well-known Hyacinth disease, and numerous others are here studied. Though many of these diseases have been recorded in Britain, their descriptions have only been published in periodical journals, and at various dates, so that the references are not easily traced when required to assist in the determination of a suspected case. In consequence of this, the present compilation by Prof. Lindau, giving a careful survey of the researches accomplished in this direction, will be of very great aid in the discrimination of a disease. The diseases are arranged according to the natural families of the plants, e.g., Conifers, Araceæ, Geraniaceæ, Liliaceæ, Iridaceæ, &c. A separate chapter deals with the bacterial diseases of the Potato, and the summary concludes with bacterial diseases of doubtful nature.

It seems only natural to find in subsequent chapters notes on nitrifying bacteria, though it is extremely difficult to say whether these organisms, with their curious symbiotic mode of life, should, or should not, be ranged under the head of plant diseases!

The student of plant-diseases will find Sorauer's *Handbuch* a great help, because of its easy and simple arrangement. The foregoing chapters in this volume deal only with diseases caused by bacteria, the succeeding ones deal with those caused by the higher fungi. After enumerating the divisions of these fungi, the author proceeds with his account of the parasitic forms and unfortunately arranges his work on the basis of a classification of the fungi. It would have been more advantageous to have adopted an arrangement according to the natural family of the host plants. This, however, would not have been quite easy, as many fungi are found on plants of different natural families, and the descriptions would then—if briefly—have had to be repeated. We presume that there will be an index of host-plants, by means of which one may more easily lay one's hand on the disease-causing fungus.

We are unable to give here instances of the many diseases investigated, but turn at once to a malady which is exciting special interest among us at the present day—the American Gooseberry-mildew, of which we have read a good deal in the columns of the *Gardeners' Chronicle* in recent times. It is interesting to note that Prof. Sorauer points out that there is a possibility that this disease may invade Germany (published in 1905), and advises fruit growers to take steps to deal with it should it be introduced. We have, of course, learned in the meantime that it has appeared in Germany. The author refers to the methods of

combating the disease in America, and states that spraying with one ounce of potassium sulphide dissolved in two or three gallons of water has given the best results. In addition, he states that a period of hot weather seems to favour the spread of the fungus—but he does not unnecessarily alarm the growers.

The four parts of this volume, now published, show plainly that this difficult subject has found its complete master. The drawings, which are plentiful, are a great help to the student and reader.

Of the third volume only one part has been issued. This part is prepared by a specialist, Dr. L. Reh, of Hamburg. He begins his subject with the diseases caused by nematoid worms (eel-worms), describing injuries to Cereals, Onions, Hyacinths, Cucumbers, Clover, Potatoes, Mangels and Strawberries. Dr. Reh gives at the conclusion of each chapter an account of the means to be used to combat the pest, and a list of its natural enemies. The following chapters deal with the injuries caused by snails, crustaceans, millipedes, &c. From what we have now seen of this work—and that is the greater part—we can thoroughly recommend it. One's only regret is that the student must master the German language before he can appreciate this work by these German authors, who deserve to be complimented for the way in which they have dealt so thoroughly with even the smallest detail of their subject, a manner too often lacking in the work of British scientists. *H. T. Güssow.*

THE COUNTRY GARDEN.

I HAVE often been struck with the lack of attention that the majority of English gardeners pay to the setting or background of the different portions of the garden. It is worth while to consider the full value that some singularly and appropriate background may have in enhancing the beauty of some particular subject. Let me enlarge somewhat, and give a few illustrations to make my meaning clearer.

I know an old garden in which Yuccas seem to have greater beauty, greater stateliness, and dignity than in any other garden I have ever seen them. Why is this? They are finer specimens than are thousands to be seen growing in other gardens, but they are planted at a considerable elevation, and you get their stern, clean-cut foliage cut out against the sky. A velvety lawn rises up into a wide, flat-topped mound, and it is on this summit that the Yuccas are grouped, very carefully grouped, for they are not overcrowded and closely massed, but with space between each—and, as I have said, nothing behind them but sky—and the effect is wonderfully characteristic.

And now to take such a plant as the Foxglove. I have seen an experienced gardener plant these in a border under a wall, when he had not the means of supplying them with a beautiful woodland background. In the one case there would have been a sense of delightful congruity and suitability, whereas, planted as they were, and charming as they were there, they had not the picturesqueness that they would have had with the wilder setting. It is a very subtle sense this sense of appropriateness. My friend had given Nicotiana and Cannas a woodland background. He never understood the mistake he had made, nor could he be made to see it. Perhaps, after all, it is a thing that has to be felt rather than seen, but it is worth a great deal to try to realise it, and it requires, I think, more especially that we study to realise the character of the plants that we use—a study that should not be difficult when dealing with plants that are represented in, or have near relationship to, our native flora, as is the case, of course, with the Foxglove. An old wall can be a charming setting for plants, so long as the right plants be chosen.

There are a few subjects of comparatively recent introduction that have already proved themselves valuable additions to our gardens. Succeeding the double Arabis came a double form of *Alyssum saxatile*. It has not made half the way it deserves to make, for I keep well within the bounds of truth when I say it is one of the indispensable subjects for late spring display in the rock garden. It does not produce seed, therefore plants must be purchased. The single form is beautiful, but this double one is far more enduring; and, instead of a brief and brilliant effect produced by masses of *Aubrieta*, *Saxifraga Composii*, and single *Alyssum*, that is to say, a splendid display of mauve, white, and clear, clean yellow, we get the same effect with the double form, and a sustained one. The other plants I have mentioned are famed for their long endurance, with the exception of the single-flowered *Alyssum*.

I do not think we experiment sufficiently with our plants. If a subject does not flourish in one position in the garden, it may do so in another. One of the most difficult positions to cater for is the hot, parched border, so far as July and the later months are concerned. These parched borders often make ideal and charming displays of colour during the earlier months. But to get plants to flower there in anything like perfection after June is a difficult matter. Among the most decorative plants that succeed better than others must be mentioned the *Galega*. It is not so good as under more favourable conditions, but still creditable. Study its roots and that will reveal the secret. It runs deep down into the soil, and the roots are strong, tough, and plentiful. It can, if it have but a deep root run, get down far below the surface and defy the surface heat and dryness.

Another subject that proves itself invaluable in the same border is *Lilium candidum*. Sometimes I have seen a cool, moist position recommended for the plant, and I have tried it over and over again in these cooler aspects, but nothing succeeds like the border that gets to powder during summer droughts. The truth is, the plants get ample moisture during their growing period, and the thorough ripening during the hottest weather is beneficial.

Yet another capital subject for this border is *Statice latifolia*, and other varieties—*S. Gmelini*, *S. sinensis*; and among the Sedums, *S. spectabile* proves a grand addition. *Practical Gardener.*

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

LATE PEARS.—One of the choicest Pears I have grown both in the North and in the South of England is *Nouvelle Fulvie*. It was named by *F. M.*, p. 133, and I consider it to be one of the very best Pears in existence. In recommending any variety of Pear, much depends upon the culture it will receive, and the soil and situation must also be taken into consideration; for instance, in the north I had fruits of *Nouvelle Fulvie* in good condition in March, but in order to keep them thus late the fruits were allowed to hang as long on the trees as possible, and when gathered they were placed in cool storage. This Pear is not grown so extensively as its merits demand, for it rarely fails to produce a crop of fruits which, when well grown, are of splendid quality. I admit it cannot be termed a handsome fruit, for it is somewhat irregular in appearance, but this does not affect its edible qualities. In the south or western counties it does well grown as a bush or pyramid tree, and in the north it should be planted against a wall. The fruits are above medium size, pyriform in shape, with a dull yellow skin that is thickly covered with russet, whilst the exposed side of the fruit is a bronzy-red colour. The flesh is melting, very juicy, and, as before stated, for a late Pear the flavour is exquisite. The tree is a compact grower. I considered it one of my best late varieties when grown as a cordon on the Quince stock. In 1900 this

variety was awarded a First-class Certificate by the Fruit and Vegetable Committee of the Royal Horticultural Society. President Barabé, a variety recently referred to by Mr. Cook, is also less known than it should be; and of this variety I can only note its value from trees grown in the south. As a cordon-trained tree it was excellent and a valuable late winter variety. This is a much newer introduction than Nouvelle Fulvie. The fruit is large, and with a clear lemon-yellow coloured skin and greenish-white flesh that is melting and possesses a pleasant aroma. The tree is of compact habit and is very prolific; grafted on the Quince stock it makes a grand bush or pyramid tree and a fruitful cordon. This variety is excellent for late winter supplies, and I have had from very young trees good fruits late in February: in the north it should be a good March variety. This Pear was also given a First-class Certificate by the Royal Horticultural Society a few seasons ago. Other well-known varieties were named by Mr. Cook. I quite agree with him in his remarks concerning Passe Crassane, but it is a rather difficult Pear to perfect in some gardens. This variety has on several occasions been staged in grand condition by Mr. Geo. Woodward, Barham Court Gardens, and at a season of the year when good Pears are very scarce. For years I failed with Passe Crassane, grown in the usual manner both as wall-trained and pyramid trees in the open, till close pruning was abandoned and a greater freedom of growth allowed, with liberal food when the fruits were swelling. I observed how well a small standard tree of this variety that was rarely pruned cropped, whereas closely-cut trained trees failed to fruit. In the north the fruit was sound well into March and possessed good flavour at that date. I fully agree with Mr. Cook concerning Knight's Monarch and how badly this variety drops; but standard trees in Worcestershire always gave a fair supply for March and even later. In this case the fruits were thinned, gathered very late, and given cool storage. Better known or recently introduced varieties include Beurré Perran (this is a delicious Pear and in season in February and March), Le Lectier, and the smaller Duchesse de Bordeaux. *G. Wythes.*

SPRING FLOWERS AT FIR GRANGE.—Although much later in flowering than usual, the numerous bulbous plants and rare shrubs in the cleverly designed and interesting gardens of W. A. Bilney, Esq., at Fir Grange, Weybridge, present a fine show. The earliest of the Daffodils, *Narcissus cyclamineus*, and *N. minimus* are fully out, some of the bulbs bearing four or five scapes each. In shady places beneath the Pine trees (these Conifers are a feature in the garden), patches of *Cyclamen hederaefolium* and *C. Coum* are in bloom, and the species of *Helleborus* in various nooks are densely set with buds. The spring Saxifrages, Hepaticas, Anemones, Snowdrops, Leucojums, and other spring flowers are well in bloom, and a continuous succession of flowers is assured. At Fir Grange are collections of Bamboos, Tree Pæonies, and many other plants which are generally regarded as "tender," but although the winter has been a long one, nothing of importance has perished, and the Bamboos have wintered excellently. A large bush of *Hamamelis arborea*, the leafless stems densely covered with its gold and claret coloured flowers, is now a very beautiful object. *J. O'B.*

ON LENDING A HAND.—Besides the many duties devolving upon the gardener and his assistants in the garden proper, there are often calls from many quarters to "lend a hand" to do something quite outside the general routine. Not that the time actually taken to do the work forms a high percentage during the year, but there is undoubtedly a disorganisation of the proper run of work when men are called off from a job "just to lower a tree." Perhaps the tree is half a mile away—across the park. "Won't take more than ten minutes." Put it at an hour before the tools are again at work, and, meanwhile, someone is waiting for the men to come back—"cannot go on until they come." In many a garden the regularity of the work suffers for want of consideration on the part of the powers that be, and the gardener has his worries increased. Through the shooting season his men may be wanted for several days—may be at in-

tervals of a week or two, or successively—to go "beating." To this there is less objection than to most hindrances of the kind, because the men not only like the change of work, but they find it to their advantage; and, moreover, there is a better chance, at such a season, of catching up the garden work. The most trying period is during spring and summer; cropping is due, the weather is suitable, all hands go out and commence to work with a will. Alas! "Please —" Who does not know that plaintive messenger? What gardener can answer him with a smile? Then, again, on many estates it is customary for a portion of the garden staff to "lend a hand" in the hay-field or corn harvest. I admit that it is not an easy matter in these days to get labourers enough to save fifty or one hundred acres of hay, even by booking them a month or two beforehand. The work must be done, and those upon the estate are often called upon to do what would be done by occasional help if that help were procurable. Thus it is that the garden is robbed of its labour when the fruit season is in full swing; weeds are growing apace, winter crops are waiting to be planted, and a hundred other things demand attention. The gardener is anxious to make the best of his fruit crop, and to secure a good start for the winter. He dislikes seeing the weeds growing, and does not feel happy to remember that to-morrow, if it is fine weather, his men will be in the harvest field, and not hoeing in the garden. Of course, there are gardens where this state of things does not exist. Some employers are sympathetic, and often try to compensate by sending farm-hands into the garden to work up the time equivalent to that which the farm received, but this does not always work out successfully; the season has gone on and cannot be overtaken; the work is strange, and after a busy and tiresome harvest the men, however willing, are necessarily spent. Such light work as picking small fruit may be done by youths or women, and this can be almost left out of consideration compared with digging, hoeing, and carting water. Many a gardener and employer can see the force of all this, but how can it best be remedied? Covert-beating, hay-making, occasional calls upon the labour staff, such as for carpet-beating, drain-opening, road-repairing, dangerous tree felling, &c., &c., must be done by someone. Pensioners of the estate may do some things, but they are few. Labour-saving instruments may accomplish much, and, so far as the farm work is concerned, this is the only remedy yet in view. As for the rest, "what cannot be cured must be endured." Mutually, the employer and the gardener must adjust their demands with as much goodwill as their good natures and the circumstances permit. To "lend a hand" may lead either to unpleasantness, or to mutual goodwill and gratitude. The former is inevitable if there is not forbearance on both sides, and the latter is equally possible if there is cheerful reciprocity. All gardeners are not diplomats, nor are employers and stewards for that matter. Still, the thing may be adjusted by careful forethought by all concerned if time is taken, notice given to each party, and the thing is not rushed. By rushing and want of consideration the best of tempers may be spoiled, but by care, what looks like failure may be turned into tolerable success. *Careful.*

AN IMPOSITION.—A correspondent writes to me from a village near Swansea:—"I purchased some Carnations at my door to-day from a man who stated that he was a representative of yours, and produced your catalogue. I should be glad to know if he is an agent of yours, and if he and his roots are genuine." As I have no representatives, I wrote for particulars. These are as follow:—A man called at a large house, when the owner was out, and produced my catalogue, saying he had travelled down to Swansea with a large order for Carnations for Mr. P. (a gentleman who has a fine house and grounds with professional gardeners), that there was a mistake somewhere, as he had some left over, those in his hand—seventeen plants, which he did not like to carry back, &c., &c. It was a lame tale, but the lady, a lover of Carnations, was tempted and bought them. My correspondent, a doctor, saw the same man, with a comrade, later in the day, still getting rid of a surplus stock of Carnations. Catalogues are easily obtained, and a good name may be jeopardised by swindlers such as these. *J. Douglas.*

CATS IN GARDENS.—*Jason* (see p. 160), would do well to found more homes for the stray cats which have been thoughtlessly and cruelly turned away by the so-called lovers of cats. An unsuccessful attempt was made, some time ago; in one of the parks, to photograph one of these castaways and her progeny under a lavender bush, where the kittens were born. Surely there are few city residents who seeing a gaunt, hungry, miserable-looking specimen of a cat preying on our only too few London songsters would be disposed to consider it "an asset of city life." *A. J. Hartless.*

CAUTION!—There is travelling at the present time a man who professes to represent a firm known as the Gibson Scotch Tweed Manufacturing Company. He represents his goods as being of extra good quality. I bought some at 5s. 6d. the yard; I took it the same night to a tailor and asked his opinion of it. He told me he could supply me with better stuff at 2s. 4d. the yard. One thing which tended to allay my suspicions was his remarkable knowledge of gardeners about the country. Among other well-known men he mentioned as among his customers were such men as Mr. Bates, Mr. Barnes, Mr. Gibson, &c., whom he professes to have served for years. I am writing to warn others. He is a man of medium height, with a ginger-coloured moustache, between 40 and 50 years of age. *One of His Dupes.*

SOCIETIES.

ROYAL METEOROLOGICAL.

MARCH 20.—The monthly meeting of this society was held on the above date. Dr. H. R. Mill (president) in the chair.

Major B. F. S. Baden-Powell gave a lecture on "The Exploration of the Air." He began by saying that the atmosphere forms a vast ocean above us, an ocean but little explored. We crawl about the ground like crabs on the bottom of the sea; we make our meteorological observations down on the ground, ignorant of all that is going on in the midst of that great expanse of air above our heads where the clouds hang about, where the rain and the hail are formed, where the lightning flashes have their origin. We look to the cross on St. Paul's, or the top of the Eiffel Tower as the most elevated points at which to observe the mechanism of the atmosphere, yet these compare to the aerial ocean but as a pin stuck in the carpet does to the air of a room. If all the clouds in the sky were suddenly solidified, in their various shapes and different elevations, what vast realms of unexplored territory there would be! But even though not solid land, there is still plenty to explore in these regions of ever-changing cloudland. If we can mount up among them, we can ascertain the temperature, the humidity, the air pressures, the electrical effects, and many other points on which we are at present very ignorant.

There are two classes of people interested in the exploration of the atmosphere: (1) The meteorologists, who study it chiefly to find out about the weather, and (2) the inventor, who would utilise it as a highway of travel. The aerial navigator will want to know all about the currents and the conditions of the air, while the meteorologist will derive the utmost benefit from the ability to visit any parts of the atmosphere. There are three means now at the service of man by which he may ascend into these desirable regions, or may send up self-recording instruments to probe the mysteries of the skies, viz., balloons, kites, and flying machines. The balloon, although at the time of its invention it was hailed with acclamation as promising the conquest of the air to man, yet it is now realised that it is not capable of much practical application. It is nevertheless useful (1) as an observatory for scientific investigation; (2) as a means of reconnaissance in war, and (3) as a most agreeable way of spending an hour or two in blissful peace and sublimity. But recently great strides have been made in the improvement of the balloon in the way of providing it with engines and propellers, so that it may be driven to any pre-determined goal. Twenty-five years ago the French Government made the first dirigible airship, and now they possess one, if not more, that seems to be a really practical air vessel of war. Count Zeppelin,

in Germany, has also produced a machine which, in point of size as well as in speed, has beaten all records. Going to the other extreme, we have small balloons now capable of attaining the greatest heights carrying self-recording instruments. Such contrivances have recently ascended to the enormous altitude of 82,000 feet, or nearly 16 miles above the surface of the earth. Closely connected with this subject of "ballons sondes," as the French call them, is that of meteorological kites. These also have been much improved in recent years, and instruments lifted by kites retained by steel wires have actually ascended to a height of 4 miles. Kites of a much larger dimension have also come into use during the last few years. At Aldershot they have been regularly introduced into the service. Men were first lifted by this means in 1895, in which year the lecturer made a number of ascents up to 100 feet high, but improvements have gradually followed until now men have actually gone up to a height of 3,000 feet, an elevation practically beyond the reach of rifle bullets, and so high as to render the aeronaut almost invisible.

Major Baden-Powell, in conclusion, referred to a subject which, if it has not hitherto had any very practical results, yet promises to bring about perhaps the most extraordinary changes in the life of man than have resulted from any other of the marvellous inventions of the 19th or 20th centuries. The flying machine has come, and it has come to stay. Years ago, people argued that it was impossible to lift in the air that which was far heavier than the air. But the advocates of the cause pointed to the birds, and there was no gainsaying that the thing was possible. Then the pessimists cried that it would not be possible to balance the apparatus without the intelligence of a bird, but models were made, finally so good as to fly for three-quarters of a mile. Then men took to gliding on wings and sailing on the wind. Huge machines were constructed with very light engines, and at last during the last two or three years, not only have men been successfully raised off the ground, but they have been able to sustain themselves in the air for half an hour at a time. Very little more remains now to be done before we can say that man has veritably conquered the air.

SCHEDULES RECEIVED.

DARLINGTON HORTICULTURAL SOCIETY'S Spring Flower Show, to be held in the Drill Hall, Darlington, on Wednesday, April 24, 1907.

BOLTON HORTICULTURAL AND CHRYSANTHEMUM SOCIETY'S twenty-first exhibition, to be held in the Albert Hall, Bolton, on Friday and Saturday, November 15 and 16.

THE WEATHER.

THE FOLLOWING SUMMARY RECORD of the weather throughout the British Islands, for the week ending March 28, is furnished from the Meteorological Office:—

GENERAL OBSERVATIONS.

The weather.—Except in the north of Scotland the greater part of the week was dry and fine, the sky being generally very free from cloud. A thunderstorm occurred at Lairg on Sunday night, and at Armagh on Tuesday; lightning was observed at some other northern stations early in the week, while on the night of Thursday there was an auroral display in various parts of Scotland, as well as at Dublin and Roche's Point.

The temperature was above the average very generally, the excess being greatest (8°1') in England E., and least (0°7') in Scotland N. and Ireland N. The highest of the maxima were recorded, as a rule, on Thursday, and ranged from 61° in the Midland Counties and 60° in England S., to 56° in Scotland E. and to 51° in Scotland N. The lowest of the minima, which occurred during the latter half of the week, varied from 28° in England S.W. (at Llangamarch Wells) and 26° in England S. and the Midland Counties to 30° in the north and north-east of Great Britain, and to 26° in the Channel Islands.

The mean temperature of the sea.—The water was rather colder than during the preceding week on many parts of the Atlantic seaboard, but warmer elsewhere, the rise being 2° at Eastbourne and Cromarty and 2°7' at Kirkwall. The actual temperature ranged from about 47° on the south-western coasts of England and Ireland to a little above 40° on the east and north-east coasts of England, and to 39°5' at Cromarty.

The rain/fall exceeded the normal in Scotland N., Ireland N., and England N.W., but was less in all other districts.

The bright sunshine was abundant in all districts except Scotland N. In England S. the percentage of the possible duration was as high as 70, and in England E. and N.E. 67, while elsewhere the percentage ranged from 64 in the Midland Counties and 62 in the English Channel, to 49 in Ireland S. and to 29 in Scotland N.

GARDENING APPOINTMENTS.

[Correspondents are requested to write the names of persons and places as legibly as possible. No charge is made for these announcements, but if a small contribution is sent, to be placed in our collecting Box for the Gardeners' Orphan Fund, it will be thankfully received and acknowledged in these columns.]

Mr. A. ALDERMAN, Gardener for the last 18 years to the late J. D. ELLIS, Esq., of Sparkin House, Workop, as Gardener to the Hon. H. W. FITZWILLIAM, Wigganhorpe Hall, York.

Mr. W. HOWE, Junr., late Gardener to Lord STANLEY, Coworth Park, Sunningdale, Berks., as Gardener to H. ROBERTSON, Esq., Alice Holt, Bentley, Farnham, Hants.

Mr. ERNEST MARKHAM, Foreman in the Gardens at King's Walden Bury, Hitchin, and previously under Mr. GEO. BURROWS, at the Dell, King's Norton, as Gardener to LADY CHICHESTER, at Arlington Court, Barnstable, Devon.

Mr. C. H. HALL, until recently Foreman in the Gardens at Swinfen Hall, Lichfield, as Gardener to CLIFFORD J. COVEY, Esq., M.P., Llantarnam Abbey, Newport, Mon. [The 2s. has been put into R.G.O.F. box.]

Mr. R. TEEL, until recently Gardener to Col. C. H. BIRD, of Crookhey Hall, Garstang, Lancs., as Steward and Gardener to G. P. FITZGERALD, Esq., The Castle, The Island, Waterford.

ANSWERS TO CORRESPONDENTS.

* * * The Editor will be glad to receive, for consideration, large photographs of horticultural subjects, suitable for forming Supplementary Illustrations to this Journal.

Books: *Farming*, by W. M. Todd, M.A., published by J. M. Dent & Co., Bedford Street, London, W.C.

CALLA ELLIOTIANA: J. E. H. Twin flowers and other variations in this plant are often received by us, but we do not remember so large a number as 12 in one batch as in your case. It is not fasciation—not twin flowered—but one of the lower leaves has become spatheaceous, probably from intensive culture. We shall be pleased to receive your help in compiling our report of the fruit-crops, and will send you a form later.

CYTISUS (GENISTA) FRAGRANS: *Niphotos*. Take cuttings of the young wood 2½ or 3 inches in length with a "heel" attached to each if possible. Insert these in sandy soil in small pots and put the pots under a bell glass or in the propagating frame in a warm house, where the atmospheric temperature is kept as high as 60° at night-time. When the cuttings have formed roots remove them from the close atmosphere of the bell-glass, or frame, and gradually inure them to a greater degree of light and air and rather less heat. Repot them into larger pots as this becomes necessary, and cultivate them in the greenhouse or partially warmed frame. With proper treatment they should make nice little plants in 5-inch pots within 12 months after the cuttings were taken.

EMPLOYMENT IN THE LONDON PARKS: J. B. In the case of Kensington Gardens, Hampton Court, Hyde, Regent, and Greenwich Parks, you must apply to the respective superintendents for a form of application. Applications for employment in the London County Council parks and gardens must be addressed to Lt.-Col. Sexby, 11, Regent Street, London.

HISTORY OF THE GARDEN PEA: P. W. H. We cannot trace the articles you mention. An exhaustive paper on the subject, delivered by Mr. N. N. Sherwood, appeared in vol. xxii., p. 239, of the *Journal of the Royal Horticultural Society*.

NAMES OF FLOWERS, FRUITS AND PLANTS.—We are anxious to oblige correspondents as far as we consistently can, but they must bear in mind that it is no part of our duty to our subscribers to name either flowers or fruits. Such work entails considerable outlay, both of time and money, and cannot be allowed to disorganise the preparations for the weekly issue, or to encroach upon time required for the conduct of the paper. Correspondents should never send more than six plants or fruits at one time: they should be very careful to pack and label them properly, to give every information as to the county the fruits are grown in, and to send ripe, or nearly ripe, specimens which show the character of the variety. By neglecting these precautions correspondents add greatly to our labour, and run the risk of delay and incorrect determinations. Correspondents not answered in one issue are requested to be so good as to consult the following numbers.

FRUITS: *Subscriber*. Kindly send another specimen. The first was rotten on arrival.—*James Green*. 1, New Bess Pool; 2, Roi de Angleterre; 3, Pear Beurré Rance. PLANTS: J. D. 1, *Buxus sempervirens* var. *rosmarinifolia*; 2 and 3, *B. s.* var. *elegantissima*; 4, *B. sempervirens* (seedling form unusual); 5, *B. s.* var. *aureo-marginata*; 6, *B. s.* var. *arborescens*.—W. W. *Iris japonica*, figured in *Bot. Mag.*, t. 873, as *Iris chinensis*, and commonly known in gardens as *Iris fimbriata*. A well-known plant.—R. O. 1, *Bletia Shepherdii*; 2, *B. verucunda*; 3, *Phaius grandifolius*; 4, *Colax jugosus*; 5, *Laelia longipes*; 6, *Maxillaria picta*.—R. N. H. *Chipping*. *Billbergia nutans*, figured in *Bot. Mag.*, t. 6423.—Mrs. L. G. The common Snowdrop, *Galanthus nivalis*.

ODONTOGLOSSUMS AND IRIS: W. Notts. The darker *Odontoglossum* of which you send a photograph is probably *O. Hunnewellianum*, or it may be of the darker section of *O. Adriaenz* (*Hunnewellianum* × *crispum*), the smaller forms of which approach *O. Hunnewellianum*. The other is probably ordinary *O. Adriaenz*. These are not now very valuable. We thank you for photograph of *Iris japonica* (*fimbriata*). If flowers of the *Odontoglossums* were sent, we could give a better opinion.

PEAR TREE: X. Y. Z. We are not certain of the cause of failure. Send us some fruits when they are in the condition you have described. It would be as well to spray the tree directly the buds commence to open with a weak solution of the Bordeaux mixture, adding one ounce of Paris Green to 10 gallons of the diluted mixture. If the injury is caused by the Apple blossom, Weevil or the Pear midge this spray will have a deterring effect.

PELARGONIUM LEAVES: *Taxus*. The blisters on the under surface exhibit no trace of fungi. An expert entomologist can find no evidence of insects. He reports "I cannot find a trace of any organism." At present it must remain a mystery until other evidence is secured. The bleached spots greatly resemble those caused by parasitic leaf fungi, but they are entirely barren, and without any trace of mycelium. Such spots are sometimes caused by water drops. In this instance the leaves afford no clue.

PETROL FUMES AFFECTING PLANTS: *Enquirer*. You had better be guided by your gardener's advice, as he must have more knowledge of the circumstances of the case than ourselves. Make the partition as secure as possible, in order to prevent the gas from penetrating direct from the garage into the conservatory.

SITUATIONS IN THE UNITED STATES. In reply to numerous enquiries we give Mr. Bunyard's full address:—Mr. Harry Bunyard, c/o Mr. Boddington, Seedsman, New York, U.S.A. We cannot undertake the responsibility of advising anyone to undertake so serious a step, but we think a British colony such as Canada would be more suitable for British subjects. Whatever country be chosen the emigrant must take what comes and work hard.

SWEET PEAS FOR EXHIBITION IN THE FIRST WEEK OF AUGUST: *Enquirer*. Sow the seeds in about the middle of May, thus allowing the plants 10 weeks' cultivation. The ground should be deeply dug and well manured before sowing is done. The plants will need liberal supplies of water during growth and the ground about the roots should be covered with a mulch. Thin out the number of flowers on each plant, and shade the brightly coloured varieties from hot sunshine, otherwise they will be liable to "burn."

TRICHOLOIRION: E. O. J. We suspect the bulbs sent you under the above name are those of *Ixiolirion*, a member of the *Iris* family. The plant is somewhat tender, and if cultivated out-of-doors in your locality (Staffordshire) the bulbs should be planted in a warm border of light, porous soil, and facing to the south.

TULIPS DISEASED: J. R. P. The plants are affected with the Tulip disease—*Botrytis*. See answer to J. E. W. in our last issue.

COMMUNICATIONS RECEIVED.—R. H. B.—*Dunstable Gazette*—M. Gentil—J. Burt Davy—W. D. G.—H. M. V.—R. Agric. Society—E. S. S.—R. H.—E. S. C.—University of Birmingham—W. G. S.—W. B. H.—Cork—W. B. CHAMAEROPS HUMILIS L. ONCE A NATIVE OF THE RIVIERA.

IN the *Annales de la Société des Lettres, Sciences et Arts des Alpes Maritimes*, XIX. (Nice 1905), p. 263, Dr. Fritz Mader publishes a very interesting paper on *Chamaerops humilis* L., which deserves to be brought to the knowledge of readers of the *Gardeners' Chronicle* and will prove of special interest to those who are acquainted with the Riviera.

The dwarf Palm is the only representative of its family on the European Continent. It is a native of Southern Spain, stretching as far north as Catalogna and to the opposite African coast of Algiers and Morocco. It grows also in Sicily, Sardinia, and Southern Italy, but is rare in Corsica, where it has only been found in the vicinity of Bonifacio. It re-appears, however, on the island of Elba, the little Capraia isles, and, finally, on Monte Argentario, once an island, but now connected with the continent by sand dunes. It further occurs on the Adriatic coast, doubtfully in Greece,* and is said to be found in the Levant.

A comparatively short time ago the *Chamaerops humilis* was also a native of the

Riviera, where it reached the most northern limit of any Palm; that is, 43° 43' north. lat., as neither the Asiatic nor the American Palms advance so far north. Dr. Mader quotes ample proofs of its former localities on Mont Boron, at Villefranche, Eza, Monte Carlo, &c., which places form the warmest part of the Riviera, protected, as they are, by those high mountains which immediately slope down to the sea. The first to mention the dwarf Palm from this locality is Allioni, in his *Flora Pedemontana* (1785), vol. II., 363, where he states it to grow "in agrocensens." According to Mr. Burnat, author of the *Flore des Alpes Maritimes*, Pyramus De Candolle saw the plant there when he visited the spot with the well-known naturalist Risso on June 25th, 1808, but in his notes De Candolle remarks that he only saw a few "pieds." M. Gay, the French botanist, in a letter to Alphonse De Candolle (see his *Geogr. Bot.*, I., p. 152), states that he saw the plant near Beaulieu in 1821. Finally, the Abbé Montoliva informed Mr. Burnat in 1871 and 1875 that he had seen the Palm 15 or 16 years ago on the Mont Boron, near Villefranche, and that another "pied," certainly spontaneous, had been destroyed near Eza in the construction of the railway. The famous naturalist Karl Vogt is said to have seen the Palm about 1846 on inaccessible rocks of the Tête-du Chien, the steep mountain which rises immediately behind Monaco. Besides these accounts of eye-witnesses, Mr. Sauvaigo, the Directeur du Musée d'Histoire Naturelle of Nice, gives the following data:—The dwarf Palm was found near Villefranche, Beaulieu, Eza, la Petite Afrique. M. Gay saw it in 1821, Cambrésès in 1826; Mr. Cosson, guided by Risso, collected leaves of a plant in 1841, which are still preserved in his herbarium. Mr. Sauvaigo remarks that the plant had to endure the extremely cold winter of 1820, when the thermometer fell to — 10° C. (14° F.), a temperature which is happily very exceptional. Ardoine, in his *Flore des Alpes Maritimes* (1866), was the first to state that the *Chamaerops* had disappeared. Prof. Penzig, however, in a paper published in 1892 again states having heard that the plant could still be found on the rocks north of Monaco.

From this latter statement and that of Karl Vogt, it seemed possible that the *Chamaerops humilis* still existed in this particular spot. To ascertain this fact, Dr. Fritz Mader, who is perhaps the best authority on the natural history of the Riviera, explored the whole territory. As the whole of this territory lies within the zone of the French fortifications, these places cannot be visited without special permission from the French military authorities. It was therefore easily to be presumed that, if anywhere, the Palm must still be found in this region, which is always rigidly closed to the public, and thus offers the best and strongest protection to the plants growing within its limits.

Dr. Mader obtained permission, but, despite his most careful researches, he did not discover a single trace of the Palm. He found plenty of the equally interesting and rare *Leucoium hyemale* D.C. (L. nicaense Ardoine), which is very scarce in its other localities.

It seems therefore pretty certain that *Chamaerops humilis* is extinct from this

most northern locality. Dr. Mader goes on to state his opinion about this fact. Contrary to Mr. Burnat and Mr. Montoliva, who attribute the disappearance of the Palm to plant-collectors and gardeners, Dr. Mader believes that a plant of such vigorous growth as *Chamaerops humilis*, which was, and is still, considered wherever it grows, a bad weed, would never have been destroyed in this manner. According to him, it is the progressive and intense cultivation of the soil, the building of terraces, houses and roads, which are the real cause of the disappearance of the Palm. Certainly, as he truly states, the Palm prefers deep, good soil to bare rocks, and it was especially on this soil that men first settled. The *Chamaerops* having found, with a few other remarkable plants, a refuge during the ice-period in this warm corner, could not spread further, as the available land is but a narrow strip along the coast. Here the Phœnicians may have been the first to disturb it, and it has since been gradually diminishing. Its associates from the tertiary epoch, *Euphorbia dendroides*, *Cneorum tricocum*, *Lavatera maritima*, *Rhamnus Alaternus*, *Phillyrea media* and *P. augustifolia* were more fortunate. They established themselves on the sterile rocks, where few other plants rival them, and where man seldom comes to disturb them.

Thus the regrettable disappearance of the *Chamaerops humilis* is not to be attributed to changed climatic conditions. On the contrary, it flourishes in our gardens, wherever it is planted in deep, good soil. It is one of the most variable plants I know of. Nearly every specimen has its own distinct habit. The fruit is generally not worth much, although its pulpy pericarp can be eaten; it tastes like a Carob. There are, however, individuals with more fleshy fruits. Dr. Mader mentions a plant of these in a garden near Mentone. *Alwin Berger, La Mortola, Ventimiglia, Italy*. [Our figure 94 was sent us by M. Bornet from the Villa Thuret at Antibes.]

SUB-TROPICAL GARDENING IN PUBLIC PARKS.

It is surprising to find, considering the appreciation that is shown by the public for the efforts which some park authorities make to provide them with places where examples of so-called "sub-tropical" gardening can be seen, that this style of gardening is not more generally carried out.

Such gardens form one of the most attractive features of those London parks where examples of sub-tropical gardening are to be seen.

The sub-tropical gardens in Battersea Park may be cited as an example of what can be done by a public body in catering for the public taste in this direction. In the majority of cases no doubt the grants allowed for the maintenance of the parks are not liberal enough to allow any attempt being made to form and embellish such a garden with specimen Palms, Tree Ferns, Cycads, &c. Much may be done, however, in places where funds are limited by planting a selection of effective hardy trees, shrubs, and herbaceous plants; these, combined with the annual plants generally utilised for sub-tropical gardening, will, when arranged tastefully, made a good display and produce a most pleasing effect.

Although the cost of laying out and planting may in some cases prove to be heavy, the extra pleasure and enjoyment which the public derive show in a most unmistakable way that the re-

* E. de Halacsy, *Conspectus Flor Græcae*, III., 290, mentions it as cultivated only.

turn on the money expended is more than enough to warrant such expenditure.

Where the laying-out of a sub-tropical garden is under contemplation, it should be borne in mind by those who are concerned that there are several points on the consideration of which will depend to a great extent the success or failure of the undertaking. Every plant that is utilised for sub-tropical gardening must be

nature usually made use of in the beds and borders. The shelter is very necessary, for the majority of the plants used are those having a stately habit and large foliage, and if they were exposed to winds they would get weather-beaten and present a most unprepossessing appearance.

The soil in the beds and borders must be rich, light, porous, and well drained; such a soil absorbs heat readily and is well fitted to en-

My intention is to confine my remarks to the more hardy subjects for such a garden.

AILANTHUS GLANDULOSA is one of the most ornamental trees. It is a very striking plant, and is suitable for planting in groups or to form isolated specimens in the grass. It is best when grown on the single stem principle, allowing only one growth to develop, which should be

FIG. 94.—*CHAMAEROPS HUMILIS* VAR. (For text see page 213.)

grown under the most favourable conditions, so as to encourage the development of luxuriant growth.

Situation, soil, &c.—The site for the garden must be one having a south or south-west aspect, and having shelter on all the other sides; this is essential, for an abundance of sun-heat that can be conserved as long as possible is necessary to promote a quick growth, more especially in those plants of an annual

courage the active root growth necessary to ensure rapid development of abundant leafage. In those places where the soil is retentive in texture, it should be taken out to the depth of 3 feet, placing in the bottom of the holes thus made 6 or 9 inches of broken bricks or similar material for drainage, well breaking the bottom soil before placing the drainage material in position, then filling up with the soil recommended above.

pruned back to two buds during winter, the strongest being selected when signs of growth take place in spring, the weakest shoot being removed. Under good cultivation, the selected shoot will grow to a height of not less than 8 feet, and the pinnate leaves will reach upwards of 6 feet in length. It requires a fairly light soil, enriched with liberal dressings of well-decayed manure during the growing season. It may be propagated by root cuttings.

ACER PALMATUM, and varieties.—These are very beautiful small shrubs, with foliage of various tints of bronze, crimson, red, and yellow, and are very desirable for planting in the foreground of borders with taller subjects at the back. They are best when planted in a light soil, rather poor in quality; care should always be taken when planting that the roots cannot gain access to beds or borders containing rich soil, or the brilliant colour of the leaves will be displaced, and they will assume a dull colour, caused by the vigorous growth which will ensue when the roots come in contact with manure. When there are signs of exhaustion, a slight dressing of leaf-mould will be quite sufficient as a stimulant. They are propagated by grafting and budding.

A. ALIA SPINOSA and **A. CHINENSIS**.—These small trees prove hardy in the southern counties, but they are seldom seen growing out of doors. Where they can be planted in a warm corner, in light, dry soil, they can be depended on to make clean and vigorous growth. *A. chinensis* grows 5 to 6 feet, and *A. spinosa* 10 to 12 feet high. They may be propagated by stem and root cuttings.

CATALPA BIGNONIODES and **C. BIGNONIODES AUREA** are both excellent. The former may be planted in any suitable position where there is plenty of room for it to develop into a standard, specimen tree. It is very attractive and showy when in flower in midsummer. The variety *aurea* is very ornamental and well suited for planting in the grass, where the highly-coloured foliage is shown off to perfection. They thrive in any soil of fair quality and texture, and are propagated by seed, cuttings, and layers.

FICUS CARICA (the common Fig).—This is a most serviceable subject for planting to impart a tropical semblance to the garden, and is equally adapted for planting to form isolated specimens, or in association with other subjects in the borders, &c. It luxuriates in a free, rich, sandy loam, and is propagated by cuttings.

GYMNOCLADUS CANADENSIS.—The large bipinnate leaves of this species make it very ornamental, and it is a very suitable tree to plant in the borders to form a background to plants less in stature. It may be grown on the single stem system or allowed to develop into an ordinary standard. It thrives best when planted in a partially-shaded position in a deep, rich, friable soil, and may be propagated by root-cuttings and by seed.

MAGNOLIA FRASERI, **M. CONSPICUA**, **M. MACROPHYLLA**, and **M. TRIPETALA** are all most desirable, and, when established, make bold specimens. They are adapted for planting to form isolated specimens in the warmest positions in the garden. They all bloom in late spring or early summer before sub-tropical bedding can be commenced; they are, however, worthy of selection, for they make handsome foliage subjects. They should be planted in a free, rich soil, to which leaf-mould may be added with advantage, unless the soil is exceptionally light, when it would be unnecessary to use it. Layering furnishes the best method of propagation.

PAULOWNIA IMPERIALIS.—This is quite indispensable, for it is one of the most stately-habited trees. It has entire, broad, pubescent leaves, which attain a length of 18 inches, and almost as much in width, when grown on the single-stem principle, and pruned back to two buds, as recommended for the *Ailanthus*. Groups planted in the grass or borders make most striking and effective objects. A free, sandy loam, liberally enriched with decayed stable manure, suits it admirably. It is propagated by cuttings and seed.

NEGUNDO ACEROIDES VARIEGATUM.—A handsome and easily-grown small tree; is adapted for planting in groups alone, or in association with any of the other subjects mentioned in this article. It flourishes in a deep, friable loam that is well drained, and may be increased by grafting and budding.

RHUS TYPHINA and **R. GLABRA** are good plants for planting in borders that skirt the main portions of the garden. They will grow freely in ordinary garden soil, and may be propagated by layers and cuttings.

SAMBUCUS NIGRA var. **AUREA** (the Golden Elder) is a good plant for utilising in damp situations where other subjects would probably fail; it is readily propagated by cuttings.

VITIS COIGNETIÆ, **V. DAVIDIANA**, **V. THUNBERGII**, and **V. VINIFERA** are climbers, that are quite first-rate in every way. They are very effective when trained upon rustic fencing, arches, or upon pyramids made by fixing stout limbs of oak in the ground, interlocking the branches so as to make them secure, or girdling the whole with iron bands, which is the most effectual way to keep the structure firm. When such rustic work becomes covered by the vine, it forms one of the most pleasing features to be seen at any time during the season. The vines should be planted in deep, rich, loamy soil. They may be increased by cuttings of the ripened wood and by eyes.

WISTARIA CHINENSIS and **W. MULTIJUGA** are plants that are adapted for utilising in the same way as the *Vitis*, to which they make a striking contrast, owing to the foliage being much lighter and more graceful than the foliage of the *Vitis*, which is of a bold character, in *V. Coignetiae* especially. *Wistarias* like a free, loamy soil. Propagated by layers.

EVERGREENS.

The following is a short list of evergreen plants that are adapted for sub-tropical gardening:—

BAMBUSA AUREA, **B. PALMATA**, **B. JAPONICA**, and **B. SIMONII** are all hardy, and are excellent subjects to plant in moist situations; they are invaluable for forming groups or single masses of greenery in the most prominent portions of the garden. They revel in a strong loam, and are easily propagated by division of the roots.

CHAMÆROPS FORTUNEI.—This Palm, if planted in warm, sheltered situations, and protected, when the weather is exceptionally cold, will survive our winters. Specimens that have become established out of doors are not common, but much admired and valued where they do exist. If medium-sized plants, that have been thoroughly well hardened and inured to our variable climate are selected and planted in good, rich loam in warm situations, and are given copious waterings in dry weather during the growing period, they will develop into good specimens in the course of a few years.

FATSIA JAPONICA proves hardy in the London parks, and, when established, soon makes fine bushes 8 feet high, and as much through. Good specimens are quite unique in character, and are very effective. A sandy loam, to which a little peat should be added, will grow this plant to perfection. It is propagated by root-cuttings.

MAGNOLIA GRANDIFLORA and **M. GLAUCA** are both excellent, and are ornamental at all seasons of the year. When they are in flower the air is laden with the fragrance of the blossoms, and the foliage is always conspicuous owing to its shining surface and bold character. They should be planted in a rich, porous loam to which leaf-mould may be added at the rate of one bushel to every four bushels of soil. Propagated by layering.

YUCCA RECURVIFOLIA, **Y. GLORIOSA** and **Y. GLORIOSA** var. **SUPERBA** are the three best of this most decorative class of plants for out-door planting. They make fine stately specimens when well grown, and when in flower they are much admired. They like a light, rich soil, and are increased by division of the roots.

There are many other trees and shrubs that might be added to this list, but sufficient have been named to furnish a selection adapted for planting in public parks, &c., where sub-tropi-

cal gardening is contemplated. In conjunction with the many herbaceous perennials and annual plants that are suitable for the same style of gardening, they are ample to furnish a garden, which would be a great attraction in all towns. Where funds are adequate, and more plants that have greater distinctive tropical characters are desired, such types as Palms, Cycads, Tree Ferns, Musas, Alocasias, &c., can be utilised, and the beauty and attractiveness of the garden will be enhanced if these can be included for its embellishment. *Puisse.*

PERADENIYA GARDENS.

REPORT OF THE GOVERNMENT MYCOLOGIST, Mr. T. PETCH, B.Sc.*

THESE gardens have been associated for so many years with the study of fungi that we naturally turn to the report of the mycologist with interest. It is, therefore, to us a matter for congratulation when we learn that the collection of fungi made by that pioneer fungologist, Dr. Thwaites, is being examined and rearranged, and that many of the fungi represented in it are being redescribed from fresh specimens. The scientific importance of this work is great, as Rev. M. J. Berkeley's descriptions were at all times extremely brief, and were in this case necessarily made from dried specimens. Systematic work is rather out of fashion just now with the younger professional botanists; it is therefore fortunate that the work has fallen into such congenial hands as it has done.

FIG. 95.—SPORES OF *PESTALOTZIA GUEPINI*, HIGHLY MAGNIFIED.

With regard to plant diseases those of the Tea plant, India-rubber tree, Cocoa, Cotton, and other economic plants seem to have received special attention.

Allusion is made to the well-known *Pestalozzia* *Guepini*. In this country the parasitic fungus is very common on *Camellia* leaves, where it produces those circular grey or brown spots which are almost invariably attributed by gardeners to "sun burns." The spores are beautiful microscopic objects, pale brown in colour, fusiform in shape, divided by septa into three or four compartments, the two terminal ones being hyaline. They are borne on more or less distinct hyaline pedicels and are surmounted by two or three hyaline setae (fig. 95). The fungus causes one of the best-known diseases of the foliage of the Tea plant, the so-called "grey blight." Mr. Petch says of this "one case was reported in which the fungus attacked the leaf-stalk only and defoliated the bushes without producing the usual discoloration of the leaf. In another instance it was found on an old stem 1 inch in diameter." But the *Pestalozzia* is not confined to the Tea leaves and Tea twigs, it also occurs on the Rubber plant (*Hevea brasiliensis*), on Cocoa-nut and Rose. Experiments have been instituted at Peradeniya to ascertain whether these plants are attacked by the same or different species of *Pestalozzia*.

Many tropical plant diseases seem to be due to parasitic *Pyrenomycetes*. Attempts have been made at Peradeniya to differentiate the numerous root diseases of the Tea shrub, which have been grouped under the name of *Rosellinia*. A new

*Ceylon Administration Reports, 1906, Royal Botanical Gardens. Dr. J. C. Willis, F.L.S., Director Royal Botanical Gardens.

stem disease of the Tea plant is described, caused by *Massaria theicola* (n. sp.), in which the fungus attacks the stem and runs upwards and downwards in the vessels of the wood. "It frequently affects one side only, crossing the bases of the branches and cutting them off from the water supply, thus causing them to wither without being actually attacked by the fungus. When it is more generally distributed through the stem the leaves turn yellow and fall off; new sickly shoots are then produced which exist until the water supply is cut off altogether and the bush dies. The fungus is not visible externally but internally, the discoloured wood definitely indicates the diseased areas, and in the blackened bark the minute 'perithecia' appear as white circular spots if the stem is scraped lightly." A similar stem disease is caused by *Aglaospora aculeata* (n. sp.). In this, however, the affected branches produce black thorns and the progress from branch to branch is slower. The diseased conditions produced by these *Pyrenomycetes* are so interesting that now attention has been drawn to them other members of the same group of fungi will have to be watched in

The decoration of the stakes or plant-supports with empty egg shells (and which is well-nigh universal) adds to the bizarre appearance, though it hardly contributes to beauty.

The sacrifice entailed by the upkeep of a half-dozen of window-plants amounts to a good deal during the dry season, where, in many cases, the water for all household purposes is carried in empty tins from distant hydrants, or, in many well-known cases, is carried in bamboo tubes from wells more than one mile away!

On the other hand, the Filipino house-plant, by a process akin to survival of the fittest, like their unfed dogs, fowls, and swine, comes to acquiesce in drought conditions in a manner that is little short of marvellous.

Species of *Codiaeum*, *Panax*, *Hibiscus*, and *Palms* (all prime favourites) live for a month on a water supply that our gardeners would not consider a fair daily ration.

Still more remarkable is their system of potting, which greatly aggravates the dry-as-dust conditions. Most noticeable is this in *Palms*, which, as they become pot-bound and emit roots at the collar, are mounded up with soil until

Strongylodon macrobotrys (Gray) (Leguminosæ), until overtaken by neglect, was found in the gardens of one or two Spaniards. Their gardens are generally surrounded by high stone walls, the north side of which afforded a suitable environment for the growth of this horticultural prize. So long as the wall was kept cool by frequent syringings, these precious plants thrive. I have never met them except in shady ravines, that were kept cool by the fall of cascades of water. In such places the temperature will be but 65° F., and rise to 80° F. in the drier shade of the woods one hundred yards away. It is most likely that conditions suitable for *Lapageria* would fit them fairly well. The difficulties of cultivation are not so great as is the procuring of seed. Lucky, indeed, is the collector who revisits a plant which has been a perfect sea of bloom if he finds the single pod which contains its single seed.

It is probably on this account that the seed is not listed in catalogues, nor has the plant, so far as I know, found its way into greenhouse cultivation. *Wm. S. Lyon, Horticulturist, Bureau of Agriculture, Manila.*

FIG. 96.—CROSS SECTION OF OAK TRUNK HAVING A CIRCUMFERENCE OF 21 FEET.

this country. With regard to the *Pestalozzia* on the leaves of the Rubber plant, Mr. Petch points out that while it is comparatively harmless on the leaves it kills the seedlings when it attacks the stem at the collar. Several new species of parasitic and semi-parasitic fungi are referred to in the report, e.g., *Diplodia zebrina*, *Nectria diversispora*, *Sphaeronaema album*, *Glæosporium brunneum*, *Colletotrichum heveæ*, *Asterina tenuissima*, *Ceratoporus productum*, *Botryodiplodia elasticae*, *Sphaerella crotalarizæ*, &c. C. B. P.

FOREIGN CORRESPONDENCE.

THE GARDENS OF MANILA.

THE Filipino has an inborn love for house-plants. It is within conservative limits to say that the homes of the well-to-do *all* contain pot-plants; that in the slums of the big cities, among those whose daily family expenditures for existence does not exceed sixpence, 40 per cent. of the houses contain one or more house or window-plants. In all, quite 60 per cent. or more of the dwellings are so decorated; a condition that probably will not be found in any other large city in the world.

Their taste in plants is quite another matter.

It becomes a more or less conical heap that effectually sheds all water. During the continuous rains of the wet season the soil, of course, gets wet through, but for the other five or six months, one half-inch beneath the surface the soil is dust dry.

Actinorrhizis Calapparia (Palmaceæ) seems to withstand this astonishing treatment for three or four years before it finally succumbs.

In so calling this plant, I am following existing descriptions, but have lately been informed that the author has decided it to belong to a new species and genus. This charming Pinanga-like Palm is one of the most attractive medium-sized representatives of the family which occurs in the Philippine Islands. Its abundant fruits, the size of a Gooseberry, and of brilliant vermilion-red, make it truly spectacular. The maximum height of the plant is about 20 feet, and it flowers and fruits in about the sixth year. Ours is the world-wide story of the prophet without honour in his own country. *Quisqualis indica* is only found in one garden of Manila. In the suburbs, about four miles out, a single plant or sheet of it occurs that has taken possession of a rocky escarpment on the banks of the Pasig, and has fallen in billowy cascades to the water's edge. It covers an area of approximately 900 square feet, and, when in flower, is a never-to-be-forgotten sight.

OAKS IN BEDFORDSHIRE, &c.

TREES, like animals, may be infinitely little or infinitely huge, and those of the latter description often astonish us by their colossal proportions, while the former sometimes escape our notice, unless revealed by the aid of the microscope. To study the development of plants their mere size presents to us some curious contrasts. The giant Oak depicted in the illustration at fig. 96 shows one of those colossal giants which Bedfordshire has for many years been noted. The Oak, as exhibited on the carriage, is from 9 to 10 feet in length, with a circumference of 21 feet 4 feet from the ground, and is a fair representation of those fine old Oaks which are to be seen in Ampthill Park, Woburn Park, Wrest Park, &c., &c., in this and adjoining counties.

The ages of these ponderous Oaks are very doubtful. But that fine, gigantic old Oak in Panshanger Park, Hertfordshire, which has a girth of 21 feet 8 inches at 4 feet from the ground, and which, I understand, from good authority, was, a hundred years ago, an enormous tree, is still growing luxuriantly. But when we read of giant Oaks on the Continent, our British Oaks appear insignificant in comparison with them. Ray mentions an Oak existing in his time in Germany which was of such dimensions that it had been transformed into a citadel. Another of our most illustrious and philosophic botanists, Ray, measured the trunk of this celebrated Oak, and found that it was 30 feet in circumference near the ground. Evelyn and Loudon, in their works, represent several other trees with openings through which a knight completely equipped could pass freely. *George Mackinlay, Wrest Park, Bedfordshire.*

ODONTOGLOSSUM CRISPUM ROSEMARY.

THE beautiful variety of true *Odontoglossum crispum* type, shown at fig. 97, was exhibited by Major G. L. Holford, C.I.E. (gardener Mr. H. Alexander), at the meeting of the Royal Horticultural Society on March 19, when it was given an Award of Merit by the Orchid Committee. The flower, as is shown in our figure, is very broad in both the sepals and the petals, which measured nearly 5 inches across in their broadest part. The flowers are white, with a slight suffusion of rose. The inflorescence exhibited was carrying nine flowers.

TREES AND SHRUBS.

RETINOSPORAS.

THE Retinosporas include some of our best hardy evergreen shrubs. They are youth-forms of several species of Conifers, either Juniperus, Thuya, or Cupressus, but are, in the majority of gardens, still found and referred to as Retinosporas. That they are eminently suited for the embellishment of our lawns and pleasure grounds few persons will deny; their Fern-like foliage, symmetrical growth, and beautiful tints of the many varieties claim from the planter more than passing notice. They thrive best in a good sandy loam, yet grand specimens are to be found growing in retentive soils with a porous substratum that enables the water to drain from about their roots. Autumn planting is preferable on most soils, particularly where it is of a light or sandy nature, for planted at this time the roots have a much better chance of laying

yards. Planted in the best of ground, few of the varieties reach 40 feet in height in the same number of years, with the exception, perhaps, of *R. obtusa* (*Cupressus obtusa*). [A true species.—ED.] This tree forms a beautiful specimen, and is much admired for its bright shining foliage. There are several varieties of *R. obtusa*: *R. aurea* forms a neat shrub of small dimensions, with deep golden-coloured foliage during the growing season, and changing to a dark green shade the following year. We have two good specimens of this form about 25 feet high and 15 feet through at their base, the lower branches sweeping the turf. There is also *R. obtusa compacta*, a robust yet dwarf-growing variety of much excellence. *R. filicoides* is another dwarf, dense-growing shrub, with deep green foliage, while *R. filicoides aurea*, sometimes met with under the name of *R. tetragona aurea*, is similar in growth, but has rich golden foliage, as its name implies. *R.*

being a golden yellow colour that changes to a deep green as the season advances. Last, but not least, is the lovely *R. squarrosa* [a form of *Cupressus pisifera*]. This Retinospora is remarkably distinct from all the others; it is a real gem; the bluish-grey tint of its foliage is remarkably handsome. *J. Mayne, Bicton.*

ERICA LUSITANICA.

ALTHOUGH in the neighbourhood of London this species does not assume the proportions it does in Devonshire, Cornwall and other places, where the climatic conditions are eminently suitable for shrubs from semi-tropical regions, the succession of mild winters that have been experienced since 1895, has resulted in the production of fairly good specimens. At Kew a number of plants are now nicely in bloom, and will remain in good condition for some time to come. It is a native of Spain and Portugal, and is known in many gardens under the name of *E. codonodes*, which is really a synonym. The principal characteristics of the species are its many upright branches, clothed thickly with tiny, dark green leaves, and its innumerable small, white blossoms, which, contrasted with the dainty foliage, forms a charming picture. Mature specimens rise to a considerable height, but smaller examples, 2 to 4 feet high and as much through, are very effective. Planted firmly in sweet, sandy soil, containing a little peat, it grows rapidly, and in three or four years, from cuttings, good-sized plants are formed. For a cool greenhouse, a few specimens, placed in pots in autumn, form an acceptable addition. *W. D.* [For a good figure see our number for February 6, 1904, fig. 41.]

THE WESTERN CATALPA

(*C. cordifolia* alias *C. speciosa*).

MR. BEAN contributes to the *Kew Bulletin* (No. 2, 1897, p. 43), a note on this tree, the timber of which is remarkable for its power of resisting decay in damp places. It is a native of moist, fertile situations in Illinois, Kentucky, and other parts of the United States. Mr. Bean points out the distinctive characters between this species and the common Catalpa, which is of little value as a timber tree, whereas the Western Catalpa is in large demand for railway sleepers, gate-posts, telegraph poles, &c. The tree has so far proved hardy at Kew, but it is not recommended for planting on an extensive scale in Britain owing to its slow growth.

CONIFERS AT DURRIS, ABERDEENSHIRE.

PICEA OMORICA seems to find here a congenial home, but whether it will ever produce a bulk of timber sufficient to warrant its inclusion in our list of timber trees remains to be seen. *Athrotaxis laxifolia* makes a striking specimen tree, and lately has begun to produce fertile seed. I have raised a number of varieties of the Douglas Fir. One of these at present seems as if it might be a cross with some other species, whilst amongst the others there are a number of forms and colours. I have at present over a million of seedlings, and no doubt there will be a plentiful crop of seed-sports amongst them. No other tree with which I am acquainted seems to be endowed with such a tendency to reproduce freaks, and this will no doubt militate against its value as a timber tree. I am convinced that the line of division between the two species *Abies magnifica* and *A. nobilis* is a very thin one. Since having it, I have examined a number of leaves of what I know to be true *nobilis*, and find in all of them the groove from base to point. Taking into consideration the form of the tree, the size of the seed, the difference in cone and in leaf, I am inclined to think "if we hear in the voice of Jacob we also discern the hands of Esau." The foliage, and especially in the older branches, is very much lighter on *magnifica* than in *nobilis*, and I believe if you saw the trees as they grow you would detect a marked contrast in them. *C.*

FIG. 97.—ODONTOGLOSSUM CRISPUM ROSEMARY: FLOWER WHITE, WITH SLIGHT SUFFUSION OF ROSE AND SPOTTED LIP, NATURAL SIZE.

hold of the soil, and are thus better enabled to withstand a spell of drought the following summer. A great mistake was made in years gone by in planting Conifers too closely, but the planter was not entirely to blame, especially when dealing with plants newly introduced, for he was not aware of the dimensions of the adult tree. It is sometimes advisable to plant closely for immediate effect, but the "riders," or super-numeraries, should be removed as soon as crowding is apparent. Retinosporas do not develop into large trees, consequently they are more suited for planting in small or medium-sized pleasure grounds than in large parks. The varieties of Retinosporas are rather numerous, but most of them deserve a place in our gardens, while many are most serviceable for standing on verandahs, unheated conservatories, or in court-

ericoides forms a conical bush, bright green foliage, with a ruddy tint in winter. *R. pisifera* (*Cupressus pisifera*) [A true species.—ED.] forms a pleasing specimen, but it is much smaller than *R. obtusa*, and also of more slender growth. It is a quick-growing species, with long, leathery foliage, the variety *aurea* being similar in growth, but with terminal shoots of a rich golden hue. *R. pisifera filifera*, *R. p. f. aurea*, and *R. p. f. gracilis*, are all low, prostrate-growing shrubs, suitable for planting in quite small gardens. The beautiful *R. plumosa* is a young state of *R. pisifera*, of dwarf habit, and should be included in the smallest collection of Conifers. There are also other forms known as *plumosa argentea* and *p. alba picta*: these both have creamy-white foliage. *R. plumosa aurea* is very ornamental, the foliage

PILLAR PLANTS.

MUCH may be done to add to the interest and beauty of the ordinary shrubbery by the introduction of suitable pillar plants, evergreen, as well as the ordinary deciduous flowering subjects, of which Honeysuckles and Clematis are fair examples. Evergreen climbing plants are most useful during the winter months in adding a variety of colour to an otherwise dull part of the garden.

For instance, a pillar 12 feet high, perfectly clothed with Golden Ivy, cannot fail to be an object of interest at all seasons. As a rule, the ordinary shrubbery is none too interesting, and the main object of many shrubberies is to hide from view some objectionable feature.

Shrubbery borders can be made especially interesting when a due proportion of choice flowering subjects are chosen to accompany the ordinary evergreens, and the inclusion of pillar plants must not be neglected.

Poles for supporting the various pillar plants in narrow borders or small shrubberies should not be less than 12 feet in height and 4 inches in diameter at the base.

In the case of shrubberies on a large scale, the pillars should be in proportion, and a height of 14 feet high, with a diameter of 6 inches at the base, will not be out of place. The poles should be made quite secure, as nothing is more annoying than to see a perfect pillar plant blown down during the summer owing to faulty construction. The kind of pole employed must be considered, and those that are not durable, such as Scotch Fir or Spruce, must be avoided. Poles made from Larch trees are suitable. The pole should be charred and tarred at its base, when it will last a long time before rotting in the ground: the bark should be left intact, in order to add a rustic appearance. With attention in planting and care afterwards in the matters of watering, keeping the plants free from insect pests, and training the shoots, the clothing of the pillar is soon effected. It is surprising what little attention is needed afterwards to keep the pillars in order. I append a select list of suitable subjects for training on pillars, naming first those that are evergreen.

Amongst Ivies, there are several desirable kinds, both golden and variegated; the varieties dentata and atropurpurea are suitable, and the latter assumes an especially dark hue during the winter months. *Lonicera flexuosa*, *Cotoneaster Simonsii*, *Euonymus radicans variegata*, and *Crataegus pyracantha* are all suitable.

Amongst deciduous plants there is an abundance of choice subjects. Any of the rambling Roses are suitable, and especially so are those of the Wichuraiana section and also the Penzance Briars; the latter are beautiful both in blossom and when covered with their brilliant pips. The large leaved Vines such as *Vitis Thunbergii*, *V. Coignetiae*, *V. purpurea*; *Ampelopsis hederacea*—this in the early autumn gives a touch of colour that is always appreciated; *Jasminum nudiflorum*, with its golden-yellow blossoms in February and onwards; and Honeysuckles in great variety are recommended.

Mention must also be made of the free-flowering *Polygonum Baldschuanicum* and *Pyrus japonica* in its many coloured forms. No list would be complete without it contained *Clematis montana*, a plant highly desirable for effect in early spring; *C. Jackmanii*, blooming in early autumn, and the sweetly perfumed *C. flammula*, flowering in September and onwards. Nor must the *C. coccinea* hybrids, such as *Duchess of Albany* (bright pink), *Grace Darling* (rose-carmine), and *Sir Trevor Lawrence* with its campanulate bright crimson blossoms, be omitted. The richly-coloured and quick-growing *Actinidia arguta* should also be included in a representative collection of pillar plants. E. M.

The Week's Work.

PLANTS UNDER GLASS.

By J. G. WESTON, Gardener to H. J. KING, Esq.,
Eastwell Park, Kent.

Border Carnations for flowering in pots.—Where a batch of these has been wintered in cool frames, and the plants have not already been shifted into 7 or 8-inch pots, let this be done without delay, using a similar compost to that recommended in a previous calendar (see p. 155) for Malmesbury Carnations. Pot firmly, and after making the plants secure to stakes, place them on a bed of ashes in a sheltered position out-of-doors. Though border Carnations are usually grown quite successfully in the open border, it is a good plan to have a batch in pots for greenhouse or conservatory decoration. Especially is this advisable if blooms of extra size and quality are wanted for exhibition, or for testing the newer varieties, or for any other special purpose. By removing them into a house just before the buds are likely to burst, they may be sheltered from the weather, but on no account place them under glass before the plants have reached this stage. Such plants can be much more easily shaded, thus prolonging the blooming period.

Hibiscus.—The warm-house varieties of the *H. rosa-sinensis* type, of which brilliantissimus and the double-flowered miniatus are good examples, are worth growing for their free-blooming qualities, although the flowers are of a fleeting character. If the plants are in pots, they were probably pruned back a few weeks ago, and are now breaking strongly into growth, being therefore in a suitable condition for re-potting or for receiving a rich top-dressing, whichever treatment is deemed to be most called for. These plants succeed well in good loam, but extra good drainage should be provided, as they need large quantities of water when in full growth. They should be syringed twice daily to keep down red spider, to attacks of which they are very liable, especially if allowed to become too dry when growing rapidly. Cuttings of the young shoots, if taken with a small heel, will readily make roots if inserted in sandy soil and placed in the propagating frame in the stove.

Marantas.—Examine these handsome stove plants and divide any that are getting too large for the purpose for which they are required. The smaller plants should be potted on, using soil of a rich and porous description. Let the plants be placed in the warmest part of the stove, and shaded from bright sunshine, syringing them frequently all through the growing season. Amongst the many beautiful varieties, *M. arundinacea variegata* (*Phrynium variegatum*) is generally admired when well grown, and if towards the end of the summer more air and less heat are given these plants, they may then be used with safety for decorative purposes in comparatively cool places.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower to Sir TREVOR LAWRENCE,
Bart., Burford, Surrey.

Heating and ventilation.—The month of April is generally a troublesome period for those who have the management of Orchids; the sudden changes between sunshine, shade, heat, and cold are so numerous, that it is almost impossible to keep the atmosphere of the Orchid houses at anything like a regular temperature, although careful shading and ventilation oftentimes serve to prevent violent fluctuations. The heating apparatus must also be attended to with unusual care. Even in the hottest divisions the water pipes should be kept moderately warm during the middle hours of the day, so that when the sun becomes unexpectedly obscured by heavy clouds, the grower can, by closing the ventilators, avoid any extreme or sudden fall in the temperatures.

Shading.—At this particular time of the year the sun is often so powerful that it is dangerous, especially in a mixed collection, to expose the plants to its full glare, even the foliage of some tender plants being liable to receive injury in a very short space of time. To counteract this, we stipple the glass outside very thinly with a mixture of ordinary flour and water, choosing a fine bright day, so that the

mixture will dry quickly on the glass. The glass is first thoroughly cleansed, and allowed to dry. By adopting this plan, the blinds do not require so much looking after, and there is no need to keep working them up and down at every trifling change in the weather. It is not necessary to let them down nearly so early in the morning, and they may be drawn up again several hours earlier in the afternoon, the plants thus receiving far more natural sun-heat than when the blinds are employed exclusively. The permanent shading also assists the cultivator to preserve a steady degree of heat in the various departments. During the very hot weather experienced last summer we found this shading, in addition to the lattice-wood blinds, very useful for the *Odontoglossum* and intermediate houses.

Temperatures.—Owing to the increase of sun-heat, the atmospheric temperatures during day and night in the various divisions should be considerably raised. In the providing of more heat see that the atmosphere in the houses does not get too dry, otherwise thrips and red spider will quickly appear. Damp well between the pots two or three times each day during bright sunshine, and remember that most of the plants will be greatly benefited by light sprayings overhead. Whether insect pests be present or not, we periodically vaporise the houses with the XL-All compound, and we close the house rather earlier than usual for this purpose. Keep the blinds down if there be sunshine, and obtain a moist atmosphere in the house as the fumes from the compound are more effectual in a damp, than dry atmosphere. Scale insects are also easily kept in check by the same means.

THE HARDY FRUIT GARDEN.

By J. MAYNE, Gardener to the Hon. MARK ROLLE,
Bicton, East Devon.

Apricot trees are in bloom here, and although 8° and 9° of frost are registered on most nights, the atmosphere is very dry, and no injury has yet been caused to the flowers. The variety Breda was the first to open its flowers, and the tiny embryo fruits now show in plenty; it may be hoped that other varieties will set as good a crop. As soon as the leaves unfold, make a diligent search for the tiny maggot every few days. It is too early to write about disbudding of shoots or thinning of the fruit, but care may be recommended in respect to the roots, which should not be allowed to suffer in the least degree from drought. Snails are often a pest on wall fruit trees, quickly spoiling many tiny fruits. Apply lime at the base of the wall, and search the trees with a lamp at night.

Peach trees being very subject to attacks of aphid, the cultivator should be watchful from the time the blossoms open until quite late into the summer, notwithstanding that the trees were properly washed in winter. Ants are a true guide to the presence of aphid, for they are always busy where this pest abounds. Carefully examine each tree at frequent intervals, and dust a little tobacco powder over leaf and flower wherever this troublesome pest can be seen. In bad cases the powder should be rubbed in with the fingers; this will kill many of them, and the powder can be easily washed off with the syringe when the weather and the state of the trees will allow this to be done.

Hoing, &c.—Although weeds are not so much in evidence as when showery weather prevails, the hoe should not be laid aside entirely. The condition of the ground is improved, and the roots are benefited when the surface soil is kept frequently stirred during drought. Those who, like the present writer, plant out their forced plants of Strawberries should well manure and trench or double-dig the quarter for their reception. If this work has been done already, so much the better. Late Strawberry plants fruited in unheated structures are the best for this purpose, and such plants need not be set out for another month at least, by which time warmer nights may be looked for. We consider we gain quite a year by this method over planting runners, one plant being capable of producing as many fruits as half a dozen runners planted in the August of the same year, but it must be conceded that the latter, when planted on warm, sunny borders, usually ripen their fruit a week or 10 days earlier, which is an important matter to many gardeners.

THE FLOWER GARDEN.

By A. C. BARTLETT, Gardener to Mrs. Ford, Pencarrow, Cornwall.

Herbaceous perennials.—Where the soil is of a heavy and retentive nature, the present time is suitable for planting new subjects in the mixed borders. The vacant places, which were dug during the winter and left rough, should now be levelled, breaking up the clods before the planting is done.

Spring bedding.—While the spring display is at its best, notes should be taken of the successes and failures, and plans made for next autumn's planting, so that the necessary stocks of plants may be grown, and the correct quantities of bulbs procured. The arrangements will, of course, depend entirely on the personal taste of the owner of the garden. Retinosporas, variegated Hollies, and many other evergreen shrubs are planted in large beds in the spring garden with good effect, but a more extended use of spring-flowering shrubs might, with advantage, be made, not only in the larger beds, but also in the smaller ones. Shapely bushes, ranging from one to four or five feet in height (or even taller), according to the size and nature of the bed, of such shrubs as the flowering Currant (*Ribes sanguineum*), *Berberis Darwinii*, *Jasminum nudiflorum*, tied up into pillar-form, the double-flowered Peaches, and *Magnolia stellata*, when discreetly associated with the conventional spring bedding plants, would add greatly to the interest of this phase of gardening, and improve the effect by relieving the appearance of flatness which too often prevails.

Violas.—At the first suitable opportunity, these plants should be placed in their flowering quarters. The Viola thrives best in a deeply-worked rich soil. Partial shade during the middle of the day is beneficial, and plenty of moisture throughout the season is essential.

Amaryllis Belladonna.—Apply an occasional dose of artificial manure while growth is in progress, because the quality and quantity of the flowers next autumn will depend largely on the character of the growth made this season. As these beautiful bulbous plants are usually grown in borders against walls, copious waterings may be necessary for them if the present dry conditions continue.

FRUITS UNDER GLASS.

By ALEXANDER KIRK, Gardener to J. THOMSON PATON, Esq., Norwood, Alloa, Clackmannanshire.

Late Vines.—The buds on late Vines are now swelling fast, as the natural growing season has commenced. Test the inside borders at once, and if it is necessary, make a thorough application of tepid water. This watering will be sufficient until after the fruit has set. Keep the house rather close, and maintain a moist atmosphere by damping down the paths and borders twice each day. Admit air when the weather is favourable only, closing the ventilators early in the afternoon or as soon as the atmospheric temperature of the house falls to 78°. The temperature during the night should be at about 50° to 55°. Close the hot-water valves in the morning, opening them again in the evening. Great care must be exercised in the application of artificial heat at this stage, as the roots are not yet active. As soon as the buds are 1 inch long, commence to disbud, leaving one bud only on each spur, taking care to choose the best bud. When disbudding young canes, leave the buds at 18 in. apart on each side of the rod alternately. These will form the permanent spurs.

Newly-planted Vines now swelling their buds will require special attention. If the canes were not cut down at planting time to within 2½ feet of the ground level, all the buds will now have to be removed down to that distance, as to prune the canes at this time would cause them to bleed. A leader must be taken up, and the bare part of the cane can be cut back in winter. As soon as the leading shoot has made a growth 4 or 5 feet in length, pinch out the point, and afterwards let the growth run to the length of the roof.

Early Melons.—Plants which were set out in a house or pit, as previously directed, should ripen their fruit by the 1st of June. A second crop may be ripened in the same house in

September. Keep the temperature in the pit at about 65° or 70° at night. Admit air during favourable weather, closing the ventilators each day whilst the sun-heat is at 90°. Damp the paths frequently in order to keep the atmosphere moist. When watering the plants, use water in a tepid condition. Pinch and rub out the young growths at the base of the plants. Train the Melon plants on the single cordon system. Pinch the laterals at one leaf beyond the fruit. When there are three or four fully-expanded female flowers on a plant, select as many male flowers at mid-day, and, having removed the petals, place the flowers on the female flowers. At such a stage keep the atmosphere of the house much drier than usual. Be careful not to apply too much water at the roots until the fruit is set. Do not wet the plants close to the stem, but leave a space of 6 inches around each, which will help to prevent canker at the neck, but this condition can also be caused by a lack of sufficient bottom heat. As soon as the fruits are about the same size as Plums, thin them out, leaving two or three fruits on each plant. This will be a sufficient crop for single cordons planted at 18 inches apart. Sow seeds for succession.

Orchard house trees in pots or borders are now coming into flower. Keep the house cool, and do not apply fire heat except on frosty nights, just to keep the atmosphere above the freezing point. Pollinate the flowers with the camel's-hair brush at midday. Be careful not to injure the tender parts of the flowers. Always take the pollen from the most forward trees first. Repeat this operation daily until the petals commence to drop, when the young fruit will then be seen to be swelling. Just at that stage Plum trees are almost sure to be attacked with aphids. Fumigate as recommended for Peaches, and use the syringe freely against this pest.

THE KITCHEN GARDEN.

By WILLIAM H. HONESS, Gardener to C. COMBE, Esq., Cobham Park, Surrey.

The sowing of seeds.—The bright, sunny weather and winds that have prevailed recently have had a most beneficial effect on all kinds of soil, particularly on such as were well tilled during autumn and winter. The ground has therefore been in splendid condition for seed-sowing, but if this work has been delayed through any cause, it should now be pushed forward as much as possible. Make further plantings of early and second early Potatoes, and further sowings of Turnips and Turnip-rooted Beet. If seeds of Salsafy, Chicory, and Scorzonera have not already been sown, let this be done without delay, employing shallow drills drawn at 15 inches apart. When the plants are through the soil, they may be thinned out to about 12 inches apart, with the exception of the Salsafy, which may be left at distances of 9 inches. In most soils a liberal application of manure is necessary for these crops, and it should be deeply buried, or forked, and inferior roots will be the result. If, however, such crops can be afforded ground which was cropped with Celery last season, no further manure will be necessary, and under such treatment the yield of roots is generally satisfactory.

Celery and Celeriac.—If an early sowing was made last month, as previously advised, the seedlings will now be ready for pricking off. They should always be kept on the move; never by any chance allow them to get in a starved condition, or to suffer a check in any way. As soon as the plants begin to grow again after this shift, gradually accustom them to receiving more ventilation, that they may be thoroughly hardened, and perfectly fit for removal to their permanent quarters as soon as they are large enough.

Carrots and Turnips.—Early batches that have been raised from seeds sown in frames will now require thinning. Afford them frequent waterings, and gradually admit more air to the frames.

Maize or Sugar Corn.—For raising the earliest batch, sow seeds of the varieties Early Dwarf and Quarantain in a gentle heat. The seedlings should be encouraged to grow freely, and as sturdily as possible, that they may be hardened

and of considerable size for planting out in the open garden at about the end of May, or when danger from frost is past.

Early crops of vegetables, such as Peas, Cauliflowers, &c., that have been planted out on warm borders, especially if the soil is of a light nature, will require occasional waterings and overhead syringings, but these should be applied sufficiently early in the day to allow the plants to become dry again before night, for recently there have been in this district from 6 to 9 degrees of frost on most nights.

Frames on hot-beds that have been used for forcing Asparagus might now be planted with Lettuce, or with Marrows. If Marrows are planted, they should be covered up with mats at night, for some considerable time to come.

THE APIARY.

By CHLORIS.

Making a start with bees.—The following remarks apply to those who are about to start either in a small way, or with an idea of making it a business when knowledge and experience have been acquired.

What to purchase.—It is a very good time to purchase a skep, because there is very little honey stored, and, therefore, there is less likelihood of the combs breaking down when the colony is removed. A would-be purchaser should secure the advice and assistance of one who can tell him whether the colony is strong enough, and, above all, whether there is a clean bill of health. Unfortunately, many sell bees suffering from "foul brood," sometimes in ignorance, but often wilfully. If the buyer cannot have the aid of a skilled bee-keeper, then he must insist on having a written guarantee, if the seller be a total stranger. Having bought the bees, give them a puff of smoke and wait about two minutes, then overturn and give them another. This will drive the bees down, and then a cheese-cloth may be securely tied over the mouth, and the hive carried home, mouth upwards and with as little jarring as possible. Place the stock on a stand as near as possible to the bar-framed hive which they will occupy, for no person commencing would dream of keeping the bees in skeps.

Variety of bees.—Those commonly kept in this country are the English black, or German brown bee as it is sometimes termed. They are easily handled, being of even temper, they seal up the honey with beautiful white capping, but their proboscides are not so long as those of some races, therefore many sources of supply are closed to the race. To improve the breed they have been crossed with the yellow-banded Holylands, Syrian, Ligurian or Cyprian, or with the silver-banded Carniolans.

Holylands.—These are very irritable, and are seldom used in this country, or, indeed, in Western Europe.

Syrians are much the same in temper as the Holylands.

Ligurians are Italian bees with three bright, yellow bands round the upper part of the abdomen. These were the first foreign bees imported to this country about the year 1859 or 1860. They have a long tongue, and can easily reach nectar which is beyond the reach of the native bee; they are also very prolific, raising much brood and given to swarming. When extracted honey only is needed they seem to give good results, but when sections are required they are to be avoided, for they fill the cells so full that the cappings look quite watery. They are very difficult to manipulate when crossed with the native bees.

Cyprians were first introduced in Europe and America about 20 years later. They are well known for their keen desire to sting everyone and everything when handled, and, therefore, only the skilled bee-keeper can manage this race.

Carniolans.—These come from the south-west of Austria, and are noted for good tempers, but they are given to excessive swarming. They fill sections splendidly; and, probably, if a judicious selection were made of queens from colonies not given to excessive swarming and crossed with the best of native stocks, they would produce a good race of bees.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Special Notice to Correspondents.—The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.

Illustrations.—The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but he cannot be responsible for loss or injury.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY, APRIL 6—
Soc. Franc d'Hort. de Londres meet.
German Gard. Soc. meet.

TUESDAY, APRIL 9—
Devon Daffodil & Spring Fl. Sh. at Plymouth (3 days).
Brighton Spring Fl. Sh. (2 days).

WEDNESDAY, APRIL 10—
Liverpool Spring Fl. Sh. (2 days).

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich—45°7'.

ACTUAL TEMPERATURES:
LONDON.—Tuesday, April 2 (6 P.M.): Max. 50°;
Min. 47°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—Wednesday, April 3 (10 A.M.): Bar., 29·8; Temp., 51°; Weather—Overcast.

PROVINCES.—Tuesday, April 2 (6 P.M.): Max. 49°; Cornwall; Min. 43°; Ireland, N.

SALES FOR THE ENSUING WEEK.

MONDAY—
Herbaceous and Border Plants, Lilies, Roses, Azaleas, &c., at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.

TUESDAY TO FRIDAY—
The New Hall Hey collection of Orchids at New Hall Hey, Rawtenstall, near Manchester, by Protheroe & Morris, at 1.

WEDNESDAY—
Hardy Plants and Bulbs, Lilies, Palms, Azaleas, Ferns, &c., at 11; 4,000 Roses, also Fruit Trees at 1 and 3, at 67 & 68, Cheapside, E.C., by Protheroe & Morris.
Roses, Azaleas, Palms, and Bay Trees, at Steven's Rooms, King Street, Covent Garden, W.C., at 12.30.

FRIDAY—
200 cases Japanese Lilliums received direct; also Gladiolus, Palm Seeds, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 1.

Professor Henslow, as in the case of M. Jourdain and his *Ecology*,* prose, has, as he tells us, been studying, speaking, lecturing, writing on "Ecology" during the whole of his working career without knowing it. Most botanists and practical gardeners have, to a greater or lesser extent, been doing the same thing without being aware of it. Linnæus, to go no further back, frequently drew attention to it, and his "Amœnitates" furnish ample evidence that the relation of plants to their surroundings was by no means overlooked by him and his pupils. Alexander von Humboldt gave a great impetus to the study. In 1827 John Barton published an interesting lecture on the subject—now almost forgotten. Alphonse de Candolle devoted a very large portion of his "Géographie Botanique" to it, Meyen, whose treatise was translated under the auspices of the Roy. Societf, Thurmman, Watson, Lecoq all dealt with the subject, and in countless "Floras" it is treated with more or less fulness.

* Introduction to "Plant Ecology," by Rev. Prof. Henslow. Edward Stanford.

The word, then, only is new; the subject goes back to the time when men began to realise that the vegetation of a salt-marsh was different from that of a mountain moorland, and so on. Gardeners, of necessity, have always had their attention directed to the subject. It is their business to grow plants from all sorts of different localities and habitats as well as they can. As facts have accumulated, a rational grouping of them has become a necessity. Theories have been invented to account for the phenomena that are witnessed, theories worthless if not founded on facts, theories, if based on well co-ordinated facts, most fruitful in furnishing explanations of what is, in revealing what has been and what is to come. And so a new subdivision of botanical science has arisen, to which the name "Ecology" or "Ecology" is now generally given for convenience sake. A new terminology has also sprung up—plants which are found in dry climates are called "xerophytes," moisture-loving species are grouped as "hygrophytes," aquatic plants as "hydrophytes" and so forth. The plants are in outward conformation and inward structure so modified as to be adapted to the conditions in which they are found. The conformation and structure are evidently connected with the conditions under which the plants are placed, and have little to do with their family relationships. A visit to the succulent house at Kew will show Euphorbias, Stapelias, and Cactuses having the same general appearance, though, as shown in their flowers, widely separated in their family descent. Like conditions produce like effects, and so it is that the gardener is often able by the mere cursory inspection of a plant or its roots to determine the system of cultivation that is most appropriate for the plant's needs. It is soon found, however, that plants differ widely as to their power of adapting themselves to circumstances. There is no difficulty in growing Cabbages inland, for instance, though the wild plant grows on Dover cliffs under very widely different circumstances from those which encircle it in a London market garden. In fact, the great majority of plants are "mesophytes," that is, they have a much wider power of adaptation than others, which perish unless they are placed exactly under certain conditions of soil, light, moisture, temperature, or what not. This faculty of adaptation is, of course, the greatest possible boon to the cultivator. His difficulties arise with those "miffy" subjects whose requirements are more exacting and not recognisable on the surface.

Again, it must never be forgotten that plants growing wild in any particular locality do so, not necessarily because that locality is the best suited to their requirements, but because, owing to the competition with more powerful rivals, it is the only available place in which they can grow. And so it often happens that when this rivalry is neutralised and the plant is grown in gardens where enemies and rivals are kept at bay and where every facility is given to the plant to develop itself in its own way without let or hindrance, it manifests a vigour and a development to which it cannot attain under natural conditions. Mr. Henslow sees in all these matters the response of the living plant to varying conditions.

An instance of this kind was brought under our notice two or three years ago by Professor Massart. He was engaged in a minute investigation of the flora of the Belgian sand-dunes, and had instituted many experimental cultures to see what would grow and what would not thrive in that inhospitable district—experiments which had as their object not only the discovery of facts, but of the causes governing those facts. The interest attaching to these cultures was absorbing and destined no doubt to be of great value from a practical point of view. Some indication of their nature was given in our columns on November 19th, 1904, p. 345. Here we need only refer to one very striking illustration which was pointed out to us. The dunes border the sea coast; inland at a distance of not more than half a mile or a mile is the rich, fertile polder-land. Among the dunes and in the polders are numerous pools of water of various sizes, but the inhabitants of these pools, near together as they are, are different. The plants taken from the polder-pools will not grow in the wet places amid the dunes, doubtless owing to some difference in the chemical constitution of the water.

No doubt the author is right in many, perhaps in most, of his conclusions, but there are some difficulties to be overcome yet. Take the case of the Sweet Pea. We all know what that was like ten or twenty years ago. It has leapt into fashion suddenly, and see what has happened: colour, form, size, number of flowers have all been enhanced. Inferior varieties are eliminated, improved varieties are constantly selected, but the conditions remain practically the same, the details of cultivation do not materially differ, there has been no hybridisation, but, at the most, only crossing between varieties. The variation has no obvious or direct relation to the conditions of growth. Here, then, are changes of form which arise independently of any changes of condition. Other instances, especially among bud-sports, might be adduced where the variation occurs, so far as we can see, without any corresponding change of conditions.

Professor Henslow's book is modestly styled "An Introduction to Plant Ecology," but it contains also summary records of his own personal observations in Egypt, Malta, the Cape, as well as at home. In his pages he takes a supposititious pupil into the fields or woods or marshes, and, as it were, induces the pupil to cross-question the plants he meets with. Like Charles Kingsley, he asks the plant what it is, where it came from, what is the meaning and significance of its diversities of structure, what is favouring its growth, what are the obstacles it has to fight against? The search for answers to these and similar questions becomes almost exciting, certainly fascinating. We cannot conceive any more valuable training for a young gardener entering on his career than afforded by the acquisition in this manner of a knowledge of the way in which a plant lives and fulfils its duties. Space will not allow us to follow Mr. Henslow in all his chapters. The reader will possibly not agree with him in all his conclusions, but he will certainly recognise that he has produced a book of great value and suggestiveness to teachers, and one which will show the general reader that botany does not consist merely in col-

CEANOTIUS THYRSIFLORUS IN FLOWER AT KEW.

Photo by E. J. Willis.

lecting wild plants, giving them barbarous names, arranging them, and preserving them in herbaria, nor are its requirements satisfied by the examination in the laboratory of a few plants by means of scalpel, microscope, stain, or test-tube. All these are valuable aids, but they do not give that wider and deeper insight into the mysteries of plant-life that is afforded by the study of Ecology—the exhaustive investigation of plants in relation to the conditions in which they are living.

OUR SUPPLEMENTARY ILLUSTRATION.—

Whilst there are several of the Californian species of *Ceanothus* which will, in this country, grow 15 to 20 feet high against a wall, *C. thyrsiflorus* is the only one hardy enough to reach that height in the open garden near London. The species from Eastern North America—*C. americanus*—and its variety *opacus* are hardy enough, but they do not get to be more than 4 or 6 feet in height. The supplementary illustration represents a group of *C. thyrsiflorus* near the Broad Walk at Kew, the plants in which are about 15 feet high. I do not think, writes Mr. W. J. BEAN, it is generally known that there is a *Ceanothus* that is at once as hardy and as tall as this. These plants flower profusely every June. *C. thyrsiflorus* is an evergreen, with ovate leaves averaging $\frac{3}{4}$ inch in length; they vary in size, however, being frequently larger than this, and the various forms differ also in the amount of pubescence on the lower surface. The upper surface is dark green and glossy. The flowers are of a pale shade of blue, small individually like those of all *Ceanothuses*, but borne in such abundance as to make a fine display. They are arranged in a cluster of racemes, terminal and axillary, at the end of the previous year's shoots. Except that this shrub does not transplant well, it is easily cultivated. Any well-drained soil will suit it, and it can be readily propagated by cuttings made when the wood is becoming firm and put in a mild bottom heat. The species, which, as already intimated, varies in regard to its foliage in a wild state, is widely spread in California. It is commonly known as Californian Lilac. In some localities it forms a tree 35 feet high, as, for instance, in Mendocino County, where, according to SARGENT, it is associated with the Redwood and Douglas Fir. It was introduced to Britain in 1837, in which year seeds were sent to the Royal Horticultural Society. Our illustration was taken from a photograph by Mr. E. J. WALLIS.

LINNEAN SOCIETY.—The next general meeting of the society will be held at 8 p.m. on Thursday, April 18, 1907. Papers:—1, Mr. J. C. SHENSTONE, F.L.S., on "The Ecologic Functions of Stolons and Cleistogamous Flowers"; 2, Mr. A. O. WALKER, F.L.S., on "The Ecologic Aspect of Constitutional Variation in Fruit-culture"; 3, Mr. HUGH SCOTT, on "An Aberrant Form of *Coccidæ*" (communicated by Mr. J. J. LISTER, F.R.S., F.L.S.); 4, Prof. W. B. BOTTOMLEY, F.L.S., "Some Results of Inoculation of Leguminous Plants." Exhibitions:—1, Dr. GEORGE HENDERSON, F.L.S., Nepal Barley and other cereals cultivated at high altitudes in Tibet; 2, Mr. J. A. WEALE, photographs of sections of woods; 3, Mr. J. SAUNDERS, A.L.S., lantern-slides of "Witches' Rooms."

NEW BULLETIN.—The number lately issued (No. 3, 1907) contains interesting accounts of the culture of Ginseng (*Aralia quinquefolia*) in Corea; an enumeration of the plants collected in Labrador by Sir WILLIAM MACGREGOR. One main object of the collection was to ascertain

whether Lichens existed in sufficient quantities to serve as food for the reindeer. Mr. COTTON, who was entrusted with the task of identifying the species, gives a systematic enumeration of the same, from which it appears that the supply of food would be adequate for the reindeer if those animals were introduced into Labrador. Mr. BURKILL contributes an interesting note on the vegetation of Sikkim. A note is added on the use of certain fungi as decorative plants, among which are mentioned the candle-snuff fungus (*Xylaria hypoxylon*), with its jet-black, velvety stem and snow-white lip; the "crimson cup" *Dasyscypha coccinea*. Miss HARVEY HART, of Kew, has succeeded in growing this beautiful fungus from year to year by keeping the branches on which the fungus grows partly buried in moss kept constantly damp.

NATIONAL FRUIT GROWERS' FEDERATION.—

A meeting of the council will be held on Monday, April 8, at 2.30 p.m., at the Royal Horticultural Hall, Vincent Square, Westminster.

VICTORIAN ERA FUND.—Among the most useful departments of the Gardeners' Royal Benevolent Institution is the fund just named. It was instituted some years ago for the benefit of subscribers to the institution who may have been unsuccessful candidates for the full benefit of the pension at any election. The total amount granted this year to 22 such candidates amounts to £192 12s. The sums given to individual candidates have varied from £1 16s. to £12, according to the duration of life-membership or the number of annual subscriptions paid. It may be assumed that all these candidates will eventually be admitted to the full benefits of the institution. In the meantime it is our duty to see that this period of waiting shall be shortened as much as possible. Mr. G. J. INGRAM, 175, Victoria Street, is the secretary. He will gladly say how this desirable result can be attained.

DESTRUCTIVE INSECTS AND PESTS.—The following is the text of a Bill intitled an Act to extend the Destructive Insects Act, 1877, to all Pests destructive to Crops, Trees or Bushes.

"1.—(1) The Board of Agriculture and Fisheries may for the purpose of preventing the introduction into Great Britain of any insect, fungus, or other pest destructive to agricultural or horticultural crops or to trees or bushes, and for preventing the spreading in Great Britain of any such insect, fungus, or other pest, exercise all such powers as may be exercised by the Board in relation to the Colorado beetle under the Destructive Insects Act, 1877; and that Act shall apply accordingly as if in that Act the expression "insect" included all such insects, fungi and other pests, and the expression "crop" included all such crops, trees, and bushes:

Provided that the Board shall not make an order directing the payment of compensation by any local authority for the removal or destruction of any crop or any trees or bushes unless the local authority consent to make the payment.

(2) Section one of the Rules Publication Act, 1893, shall not apply to any order made under the Destructive Insects Act, 1877, or this Act.

(3) This Act shall apply to Ireland with the substitution of the Department of Agriculture and Technical Instruction for Ireland for the Board of Agriculture and Fisheries.

2.—This Act may be cited as the Destructive Insects and Pests Act, 1907, and the Destructive Insects Act, 1877, and this Act may be cited together as the Destructive Insects and Pests Acts, 1877 and 1907."

It will be noted that the Bill proposes to give to the Board of Agriculture power to act in case of need, in the same manner as was enacted in the case of the Colorado beetle. It is well that the Board should have the powers sought for, but we have not much confidence in the discretion of local authorities in such matters.

THE SWANLEY HORTICULTURAL COLLEGE.—

This institution, which has for some time past admitted women students only, forwards an encouraging report of the work of the past year. Some 68 students joined the courses of instruction, and the total number of past pupils engaged now elsewhere in gardening or in teaching gardening is 138. Various awards were won during the year, and, owing to the receipt of generous donations, the college is free from debt, and the governors consider themselves justified in planning certain improvements. It should be mentioned that there is a Colonial branch of the college, in connection with which trained students have been sent to South Africa, Nova Scotia, and Vancouver, and are doing well.

THE BLACK CURRANT MITE.—

The Board of Agriculture and Fisheries announce that a new edition of their leaflet on the Black Currant mite has been published, in which information on the treatment of this pest with lime and sulphur has been incorporated. Fruit-growers whose bushes have been attacked with the mite are advised to experiment with this process. Copies of the leaflet may be obtained gratis and post free on application to the Secretary of the Board of Agriculture and Fisheries, 4, Whitehall Place, London, S.W. Letters so addressed need not be stamped.

FORESTRY AT THE ROYAL AGRICULTURAL SHOW.—

An interesting feature of the Royal Agricultural Society's forthcoming show, to be held at Lincoln, from June 25 to 29 next, will be the Forestry Exhibition. It has been decided to offer for competition special medals in silver and bronze in 14 different sections, including classes for specimen boards of various sorts of timber, specimens showing the damage done by insect pests, the comparative quality of timber grown on different soils, and the respective ages at which it reaches marketable size, the beneficial effects of pruning when well done, and the injurious effects when badly done. There will also be classes for different descriptions of gates for farm or estate use. In addition to the above, plots of open ground space will be allotted to firms of nurserymen for the exhibition of forest trees and shrubs, and owners of forests and woodlands, and others interested are invited to send specimens for exhibition only. Forms of entry are now ready, and can be obtained on application to the Secretary of the Royal Agricultural Society, at 16, Bedford Square, London, W.C.

COLTSFOOT.—

We always welcome the first appearance of this brilliant little flower on the railway banks near London. This year we noticed it for the first time on March 3. In 1900 it was not observed till March 9, but in 1901 we saw it as early as January 21. The farmer does not look upon it with such gratification as the suburban resident. It is generally found on heavy clay land and on gault, which contains much lime. Prof. PERCEVAL, in the *Journal of the Board of Agriculture*, March, 1907, recommends farmers to hoe the plant out when in flower, so as to prevent its seeding, and to continue the work of spudding it out early in the season. The importance of ample draining need not be dwelt upon. In the meantime, we have this year, for the first time, seen the local florists availing themselves of the Coltsfoot as a pot-plant or for use in spring in window boxes. If this practice were generally adopted in our large towns, what is generally regarded as a nuisance might be esteemed as a source of profit. The fact that the flowers close at night, to re-open when the sun shines, adds to their interest. Growers always like to see evidences of life in what they cultivate.

TRANSPLANTING LARGE TREES.—We are informed that the directors of the Old Keuchenberg Botanical Gardens in Frankfurt-on-Main, Germany, having to remove their quarters, have requisitioned the services of Mr. WILLIAM BARRON, of the firm of WILLIAM BARRON & SON (of Derby) to superintend the transplanting of a Yew tree about 300 years old. The tree being about 50 feet high and 40 feet through, with a trunk 8 feet in circumference, necessitating the transport of a block of earth with the roots, about 15 feet square and 8 feet deep, the task is not an easy one, especially as this huge tree has to be taken through the town in an upright position. Amongst other ancient trees successfully transplanted are the celebrated "John Knox" Yew at Finlaystone, near Glasgow, moved by Mr. BARRON's father in 1900, and the "Buckland" Yew near Dover by his grandfather in 1880. The latter tree is over 1,100 years old, and mentioned in *Doomsday Book*.

THE MUSSEL SCALE.—In an article in the *Journal of the Board of Agriculture* for March, Mr. THEOBALD enumerates the principal insect-pests which attacked fruit plantations in 1906. Numerous insects are mentioned, but "by far the worst insect on fruit trees is the mussel scale (*Mytilaspis pomorum*), which has been sent to me no fewer than 50 times during the past summer. It has undoubtedly increased enormously during the last four years, and may be found in all parts of Great Britain. One young tree was seen in Worcestershire in which it was almost impossible to find a piece of the bark, so thickly had the 'scales' encrusted it. Needless to say, the tree was dead. One note has been sent me, saying that Chalcid parasites had materially checked it, but in the majority of specimens sent no signs of these insects could be found. So far, the only treatment seems a heavy spraying with strong paraffin emulsion, or with Mr. SPENCER PICKERING's wash of paraffin with caustic soda in winter, or dilute paraffin emulsion when the eggs are hatching out in June. Mr. COLLINGE wrote to me in June last that he was destroying it in millions with caustic alkali wash. In Kent, and also at Woburn, this was found to have no effect, thus showing how different washes have diverse effects in separate localities."

FARMING FOR LADIES, by EDITH PARK.—The writer has the invaluable recommendation of having practical experience of her subject. She wisely prepares her possible followers for a life of constant toil and uncertain profits. "Few," says the writer, "have worked as hard as I have at farming, but were I to begin life over again I should still do the same, as its pleasures far outweigh its disappointments." Miss PARK treats of the live-stock, not fully of the crops of a farm; even the subject of the garden is despatched with a short paragraph. Her publishers are Messrs. VINTON & Co., 8, Bream's Buildings, Chancery Lane, E.C.

PLANT DISEASES.—A third edition of Mr. MASSEE's *Text Book of Plant Diseases* caused by cryptogamic parasites has been published by Messrs. DUCKWORTH & Co. The third edition does not greatly differ from the second, but, in any case, it is a valuable book, which should be in every garden library. The American Gooseberry-mildew comes under notice, and whilst its dangerous character is not overlooked, it is shown that prompt and decisive action will suffice to check it. The difficulty we see is that whilst some will take all the necessary steps, others, from ignorance or carelessness, will omit to do so, and so the disease may spread. Legislative measures to prevent its introduction from abroad would be futile, and would cause much unnecessary inconvenience.

BANK HOLIDAYS AND SHOW ARRANGEMENTS.—We have often considered that the holding of Royal Horticultural Society's shows on Tuesdays following upon a Bank Holiday must necessarily impose upon exhibitors and the committees a serious amount of inconvenience. Large exhibits have to be prepared for transit, and some are even conveyed to the hall on the day before the show is held, when the time occupied in travelling is very much greater than usual. The matter was discussed at the hall on Tuesday last, and the Floral Committee sent an unanimous recommendation to the Council on the subject.

HARDY HEATHS AT KEW.—The soil of Kew, being of light quality and quite free from calcareous substances, proves to be admirably adapted for many members of the Ericaceae family. The Rhododendron Dell, the Azalea Garden, and, in a less degree, the botanical collection near King William's Temple and the groups in the sunk garden west of the Palm House, have long been popular features of the garden. Several species of Erica itself thrive particularly well, especially those that blossom in the spring. During the past few years advantage has been taken of this fact to plant a few large groups in various parts of the garden. Two more have been added during the winter, one on a portion of the railed-in wild garden near the Berberis Dell, the other on a mound south-west of the Palm House. In the former more than a thousand plants were put out. Erica mediterranea enters largely into the composition of the spring-flowering groups. It is a beautiful Heath, of which several varieties are in cultivation, one—hibernica—being found wild in the West of Ireland. Associated with it are E. lusitanica, E. arborea, E. Veitchii, and E. carnea. It is believed these groups will become permanent and effective features. The plants commence to flower in February and early March, and provide ample breadths of charming colour for three months. All that is done by way of preparation is to trench the ground and add a little peat. This is also found to provide an admirable medium for growing choice, delicate-rooted plants like Stewartia and Styrax; they not only thrive in the soil, but rejoice in the root shelter the undergrowth of Heath affords. *Kew Bulletin*.

THE BOOK OF THE OPEN AIR.—This publication is to consist of 12 parts, and Mr. EDWARD THOMAS, the editor, describes it as being a "delightful and stimulating book for every lover of nature, with coloured pictures by famous nature-artists of the day and (letterpress) by the most famous nature-writers of the day." At any rate the first part contains some very pretty pictures, reproduced from photographs and water-colour drawings, and these are detachable so can be extracted and framed. The letterpress will be appreciated by the public with whom, at present, "nature study" is a popular subject. The book is handsomely printed and got up, and the publishers are Messrs. HODDER & STOUGHTON, London.

CINERARIA.—Messrs. SUTTON showed at a recent meeting of the Royal Horticultural Society a strain of Cinerarias of a remarkable character. Both ray florets and disc florets were strap-shaped, the disc florets much shorter than those of the ray, deep violet in colour and flattish; the ray florets were twice as long, revolute, white, with only the tips violet.

THE LINDLEY MEDAL.—It was announced at the meeting of the Floral Committee of the R.H.S., on Tuesday last, that the council had determined that in future this medal shall be awarded by this committee in cases where it is desirable to express the committee's appreciation of exhibits showing superior cultivation, as was the original intention.

LAW NOTE.

A SECRET COMMISSION.

At the Greenwich County Court on March 28, the plaintiff sued a firm of horticultural builders to recover £5 10s., said to be the amount of secret commission paid by them to his gardener in connection with the building, by defendants, of a greenhouse for the plaintiff, for which he paid them £67. A letter was produced in which the gardener wrote to the firm to the effect that his master was very well pleased with the plans and the price. The letter went on to say that his master would try to get a little discount, but he [the gardener] advised them to stick to their estimate and to tell his employer that it was the lowest possible. Judgment was given for plaintiff.

THE WEATHER IN WEST HERTS.

Week ending March 27.

Warm days and cold nights. All the days of the week were decidedly warm for the time of year, and on the last three of them the temperature in the thermometer screen rose respectively to 80°, 81°, and 82°, which are very high, but not exceptionally high, readings for the latter end of March. On the three coldest nights the exposed thermometer showed from 10° to 11° of frost. Consequently, the difference each day between the lowest and highest temperatures, even in the thermometer screen, has been very great. Indeed, on two days the daily range amounted to as much as 33°, which is the highest, with three exceptions, that I have ever recorded here in March. Owing to the cold nights the ground temperatures have not risen as they otherwise would have done, and are now only 1° warmer at 2 feet deep, and 2° warmer at 1 foot deep than is seasonable. No rain fell during the week, and for the last four days only a few drops of rainwater have each day trickled through the two percolation gauges. The duration of bright sunshine was very remarkable, averaging, as it did, 8 hours 10 minutes a day, or more than double the average for the time of year. On three days the sun shone for over nine hours a day. Light airs and calms alone prevailed, and on no day was the direction of the air current from any easterly point of the compass. The mean amount of moisture in the air at 4 o'clock in the afternoon fell short of a seasonable quantity for that hour by as much as 13 per cent. On the other hand, during a thick fog on the morning of the 27th a garden wall at 8 a.m. became invisible at a distance of 10 yards. An Early River's Peach growing on a south wall in my garden came first into blossom on the 22nd, which is one day earlier than its average date in the previous 21 years, but 16 days later than last year. *E. M., Berkhamsted, March 27, 1907.*

Week ending April 3.

Remarkably warm and sunny. The present warm period has now lasted exactly three weeks, but the past week was much the warmest of the three. On five consecutive days the highest temperature in the thermometer screen ranged between 85° and 89°, which is from 14° to 18° higher than is usual at this season. The last two days in March were the warmest I have ever recorded here in that month. On the contrary, the nights were almost all cold, and on the coldest of these the exposed thermometer registered 12° of frost. The range in temperature was again exceptionally large. In fact, on one day the difference between the lowest and highest readings in the thermometer screen amounted to 37°, which is the greatest daily range in March of which I have here any record. Notwithstanding the cold nights, the ground is now 4° warmer at 2 feet deep and 5° warmer at 1 foot deep than is seasonable. After a fortnight of rainless weather there occurred a slight fall of rain during the night of the 2nd inst. No measurable quantity of rainwater has come through either percolation gauge for 10 days. The sun shone on an average for as much as nine hours a day, which is more than twice the average daily record for the time of year. Calms and light airs again prevailed. The mean amount of moisture in the air at 8 o'clock in the afternoon was as much as 19 per cent. less than a seasonable quantity for that hour.

MARCH.

Warm, dry, and exceptionally sunny.—Taken as a whole this was only a moderately warm month. The average day temperatures were, however, exceptionally high, and more especially so during the last fortnight. On the contrary the nights were, as a rule, rather cold. On the two warmest days the temperature in the thermometer screen rose respectively to 67° and 68°, both of which readings are higher than any previously recorded here in March during the last 21 years. On the coldest night the thermometer exposed on the lawn showed 15° of frost, which is rather a high extreme minimum for the month. Only once before has the average daily range in temperature in the thermometer screen been as high, and on one day the difference between the lowest and highest readings amounted to 37°, which is the greatest daily range as yet recorded here in the first spring month. Rain fell on 18 days, to the total depth of 1½ inch, which is ½ inch below the average—making this the driest March for seven years. Snow fell on only one day. The fall on that occasion was very light and melted as soon as it reached the ground. The sun shone on an average for six hours a day, or for 3 hours 20 minutes a day longer than is usual. In the last 21 years there has been only one other March as sunny. The winds varied greatly in strength. On the calmest day the rate of movement was only about half a mile an hour, whereas in the windiest hour the mean velocity was 23 miles. The most noteworthy feature as regards the wind was the almost total absence of easterly winds. In fact, for only 72 hours altogether was the direction any point between north and east. The atmosphere was singularly dry, indeed, at 3 p.m. the average amount of moisture in the air was as much as nine per cent below the March average for that hour.

OUR UNDERGROUND WATER SUPPLY.

With March came to an end the winter half of the present drainage year. The total rainfall for those six months exceeded the average quantity by 1½ inch, which is equivalent to an excess of 29,860 gallons on each acre in this district, whereas at the same time last year there was a deficiency of 16,060 gallons per acre. *E. M., Berkhamsted, April 3, 1907.*

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

JASMINUM PRIMULINUM.—A fine batch of plants of this excellent, yellow, winter-flowering plant is in bloom at Gunnersbury Park, and Mr. Geo. Reynolds, the gardener there, calls attention to its uses as a decorative plant for house or conservatory use when flowers are most needed. The plants are grown both as bushes and standards, and they are said to have bloomed continuously during the whole of the winter. Mr. Reynolds also points out the tendency of the plant under cultivation to become what is called double-flowered, most of the flowers having extra petals, while many are distinctly semi-double. This character seems to add to the durability of the blooms. A full account of the history and cultivation of *Jasminum primulinum* was given in the *Gardeners' Chronicle*, July 21, 1906, p. 44. J. O'B.

OPEN-AIR FLOWERS AT ARD CAIRN, CORK.—This has been a most extraordinary season. In my long experience and observation of bloom, I do not remember one that was so backward. All sorts of Daffodils are a month late. *Prunus pissardii*, which generally flowers after Christmas here, is only now in flower, and the bloom is very scattered on the trees. I remember in 1889 gathering a quantity of the white "Swan's Neck" Daffodil (Bishop Mann) on the 16th of February for the present Countess of Aberdeen, in order that Her Excellency should wear them at one of the late Queen's Drawing-rooms at Buckingham Palace—flowers from the open from the Green Isle. W. Baylor Harland, Ard Cairn, Cork, March 25, 1907.

CEDAR AT CHILDRICK.—In a review in the *Athenaeum* for March 23, mention is made of "Childrick, where the memory of Dr. Pocock, the first Laudian professor of Arabic, is kept green by a noble Cedar on the Rectory lawn raised by a cone he brought from Lebanon in 1646." It would be interesting to know the dimensions of this Cedar, and what claims to authenticity the above cited statement possesses. Cedrus.

THE APPLE STORE.—I read with interest Mr. Mayne's remarks on this subject on p. 208. I think with him that several of our English grown Apples compare very favourably with the foreign and colonial produce. Blenheim Pippin and Newton Wonder are, to my mind, far superior in flavour to many of the foreign varieties. Coronation is a grand keeping Apple, and gardeners would do well in planting this variety in the orchard. Apples are keeping exceptionally well this season. I have still fine, firm fruits of Blenheim Pippin, Newton Wonder, Bramley's Seedling, Beauty of Kent, Mère de Menage, Lane's Prince Albert, Annie Elizabeth, and a few others. A good fruit room is absolutely necessary in order to keep fruit so late. Some gardeners cannot possibly keep their fruit in good condition so long because they have not a suitable store. Ladies and gentlemen who grow Apples largely should always see to it that they provide a good fruit room. Then with careful gathering and handling the fruit will keep well. W. H. Collett, Huntsham Court Gardens. [Mr. Mayne sent us fresh-looking, firm fruits of all the varieties he mentioned.—ED.]

THE WEATHER IN CORNWALL.—During the month of March we experienced both extremes, having, at one time wild, stormy, unsettled weather; and at another, clear sunshine by day, and one or two degrees of frost at night. Our maximum was 57° Fahr., minimum, 27° Fahr., rain fell on 13 days, the total rainfall being 1 inch, which amount is 11 inches lower than that of last year. Everything is very dry and already we have to water established shrubs. If a heavy fall of rain does not occur very shortly, it will be serious for many plants, and especially for Rhododendrons and other surface rooting plants. H. W., Trevince.

THE MAHWA, OR MOHWA, TREE OF INDIA.—Referring to the notes on this tree (*Gardeners' Chronicle*, March 30, p. 207), it may be of some additional interest to state that the fleshy corollas are not unknown in this country. In 1877 a quantity arrived in England for trial, both for feeding pigs and for the purpose of distillation. The flesh of pigs fed upon them was said to be remarkably good, while for distilling purposes they were reported to have yielded as much as 6.16 gallons of proof spirit per cwt., the flavour of which was described as being very similar to that of Irish whiskey, but by careful rectifica-

tion it might be made exceedingly pure and free from flavour. At one time large quantities of the flowers were sent from Bombay to France, chiefly for the distillation of the spirit, but as it was found that this spirit was being used as an adulterant of French brandy, the French Government prohibited their importation. This fact gave rise to the statement that the flowers were originally exported from Bombay to France, where they were distilled, the spirit being put into French bottles, labelled as French brandy, and re-exported to Bombay in the ordinary course of trade as French brandy. This is a case on all fours with the oil from the seeds being expressed in France and contributing to the world's supply of genuine olive oil. John R. Jackson, Claremont, Lymington, Devon.

PHOTINIA SERRULATA.—In the *Gardeners' Chronicle*, March 17, 1906, p. 173, is a record of a plant which is larger than the one referred to by Mr. Cook, p. 209, although his plant is interesting seeing that it has attained to such a size and in a county which is less favourable to its growth than Cornwall. It would be very interesting to know how the young growths and the flowers have fared this spring, for, starting into growth so early, it is more than likely that they suffered injury. H. W., Trevince.

MAGNOLIAS AT LEONARDSLEE.—Magnolia Campbelli is showing for the first time several prominent flower-buds on a tree 15 to 20 feet high. The other Magnolias are also promising well, and bid fair to produce a wealth of blossoms during the spring months. The following sorts, with the exception of M. Campbelli, all flower well at Leonardslee: M. hypoleuca, creamy white. M. Lennei x; this is later than many varieties and more frequently escapes the effects of frost. M. Soulangeana x is a very pretty early flowering variety, and is a little later in flowering than M. conspicua. The variety M. S. nigra has darker flowers than the type. M. stellata is liable to be cut by frost on account of flowering very early. M. conspicua should receive protection, especially in cold districts, where it should be grown on a wall, and be protected by a blind, as in the case of fruit trees on walls. M. Fraseri also needs a sheltered position; it has sweet scented flowers, which are not showy, but the plant has very handsome foliage. M. glauca (the Swamp Bay or Laurel Magnolia) has a season of flowering extending over several months; it is a fine shrub for a damp position. M. parviflora; this species is rather tender. M. Norbertii is very free in growth. M. Watsonii requires shelter from cold winds. M. tripetala, a sheltered spot or a wind screen; it does not flower until July and August. Magnolia grandiflora, an evergreen species; succeeds best on a wall with a warm aspect. This tree should be pruned annually, cutting away all the weaker or non-flowering growths, for if this be not done, the tree is apt to become thick and too feeble in growth to produce flowers of the best quality. Magnolia kobus, of which M. gracilis is a synonym, has white flowers 5 to 6 inches in diameter. M. Thompsoniana; is really an improved form of glauca. M. conspicua (Yulan) var. Alexandrina, is an improvement on the old form of this plant. M. Van Houttei is often in bloom through nearly the whole of the summer. The present is a suitable time to give a top-dressing of a little good soil and manure to these plants. Remove some of the old soil around the roots with a fork, and then apply the new loam with some well-rotted cow manure, one-year-old leaf-soil, a little soot, and bone meal. If large shrubs or trees are growing in close proximity to the Magnolias, see that their roots are kept clear of the Magnolias. W. A. Cook, Leonardslee Gardens, March 20.

FRUIT-TREE PRUNING.—Perhaps you will allow me to correct one error in your remarks on the seventh Woburn report. Your reviewer says that "the hard-pruned tree [of Bramley, illustrated on p. 14], though less in size, has much the thicker wood, and would probably be much the best tree in another year's time." This is an excellent illustration of the way in which erroneous conclusions as to the result of pruning have arisen, through allowing ourselves to be guided by impressions, instead of by actual measurements; for, as a matter of fact, the unpruned trees are, judging by the girth of stem, about 13 per cent. thicker in the wood than the hard-

pruned ones, and in other experiments, where the thickening of the branches was matured, the adverse effect of hard pruning amounted to 29 per cent. (5th Rep., p. 114; 7th Rep. p. 18). Possibly, as we have already suggested, the hard-pruned tree may be the better of the two in 10 years' time; but this is speculation. What is fact is, that during the first 15 years of its life it has borne only one-quarter of the crop of its unpruned fellows, and it seems to be falling still more behind as time goes on. Remembering that we are dealing with dwarf trees in cultivated ground, it can scarcely be suggested that the sacrifice of so much money and labour would be justified by the bare possibility of a hard-pruned tree becoming the better one at the age of 25. The varieties selected for the main body of our experiments—Bramley, Cox, Potts, Stirling Castle—differ widely in their habits of growth, and are varieties which are much cultivated. As the cost of illustration precluded depicting them all, we, naturally, selected for the purpose those which differed most widely—Bramley and Stirling Castle. It seems scarcely reasonable to take exception to this. But it is the numerical data, and not the illustrations, which should be studied by those wishing to arrive at the truth, and these data dispose of your reviewer's suggestion that absence of pruning would be more inimical to growth with weak than with strong growers, like Bramley, for the tree-weights given on p. 7 show that it is the two weakest growers—Cox's and Stirling Castle—which show the greatest growth of any under the no-pruning treatment. Ribston Pippin and Margil, suggested by your reviewer, would scarcely be good instances to choose for experiments of general applicability, but, as a matter of fact, they were included in the 117 varieties which were investigated to a more limited extent (p. 117), and they yielded results differing but little from the mean. Your reviewer characterises as a "sweeping statement" which "will hardly be accepted," our remark that, "when there is no pruning, the crops are twice as great as where moderate pruning is adopted, and four times as great as where hard pruning is practised." But there is nothing sweeping about this statement, nor is it one to which acceptance can well be denied, for it simply refers to the results actually obtained at Woburn with certain plots during 12 years. What we wrote was: "The results when set out in this way cannot fail to be very striking, for, when there is no pruning, &c." Spencer Pickering.

The conclusions on this subject arrived at in the Woburn Experimental Fruit Farm Report are so entirely discordant with those derived from common garden practice that we are led to ask whether the conclusions in question are such as were desired, or really resulted from experiments. All experience, extending over generations of gardeners, and the world over, has shown that to secure good fruit crops pruning is essential. Trees as dense as Holly bushes is an inevitable condition if not pruned or thinned, which, of course, is pruning. Unpruned trees may produce a quantity of fruit, but how worthless! Possibly such trees may be longer lived than are pruned trees, but of what value is the long life of a worthless tree? If experiments on the practice of pruning, in Apples, for instance, are to have value, there should be planted as standards and as bush trees at least six trees of at least a dozen varieties of Apples, some strong growers, some medium, and some of weak growth. Of these trees three of each variety should be annually pruned, as is customary with each class of tree, and three left unpruned over a period of some 10 or 12 years. The real test of merit of each method being found in the fruit produce, and its market value. Could such a trial be carried out at Wisley and under the direction and observation of the Fruit Committee, something very trustworthy could be secured. Possibly many of your readers, men of lifelong experience in fruit-tree culture and pruning, may ask [in regard to such a trial] whether, in the face of that experience, the game is worth the candle, and with much justice. The fruit-grower knows that he is planting trees to produce fruit and not merely wood, hence to obtain his object he finds it is absolutely needful to prune and thin tree-heads, and very often even the roots, and he thus secures really grand fruits. A. D.

WITHERING OF PLANE LEAVES.—I noticed last year at many places in different parts of England that the London Plane, *Platanus acerifolia* (often written and spoken of as *Platanus occidentalis*, of which to my knowledge there are no large trees now in England, if, indeed, there ever were any) were invariably attacked by a fungus, which, I believe, is *Glaeosporium nervisequum*, whilst the leaves of the true Oriental Plane growing in the same places were never so attacked. I can find no reference to this distinction in print. Some good observers have supposed the withering of the young shoots of the common Plane to be due to frost and wind, but I believe that the fungus named is the sole cause. If the Oriental Plane is immune, as it seems to be, the fact points to a physiological difference between the two forms; but the origin of the London Plane is, so far as I am aware, unknown. I shall be glad if readers of the *Gardeners' Chronicle* will notice and report to me in the coming spring on this subject. *H. J. Elwes, Colesborne, Glos.*

MISTLETO ON LIME.—When visiting Essex last week I saw mistletoe growing in great luxuriance and abundance on Lime trees, and noticed that these trees had on their branches burr-like swellings, which in some cases assumed an elongate gourd-like form such as I have never observed on Lime elsewhere. It struck me that this might be wholly or partially due to the arrested growth of the branch where the mistletoe had taken root on it, though no mistletoe was now present on many of the branches so malformed. Can any reader throw any light on this? *H. J. Elwes.*

LACHENALIA NELSONI.—I was glad to see on p. 194 in the issue for March 23, the notice of *Lachenalia Nelsoni*, exhibited by Mr. Doig at Vincent Square. This lovely plant ought to be widely grown. When visiting Lord Downes' garden at Dingley, Market Harboro', recently, I saw a magnificent batch in upwards of 30 4½-inch pots. On an average there were 18 spikes of bloom to a pot, and, in addition, six hanging baskets contained about six dozen bulbs in each basket. Associated with well-grown plants of *Coleus thyrsoides*, carrying many fine spikes, they produced a most charming effect, and have been greatly admired. Mr. Clipstone, the head gardener, evidently fully understands the requirements of *Lachenalias*, as he told me his stock has been worked up in five years from only two pots of bulbs. All flower-lovers should obtain a stock of this little gem amongst greenhouse bulbous plants. *W.*

CONDY'S FLUID DOES NOT CONTAIN PERMANGANATE OF POTASH.—A subscriber to your journal has directed our attention to a misstatement respecting "Condy's Fluid," which appears in "Answers to Correspondents," page 196, in your issue dated March 23 last, subject "Palm Leaves Diseased." We have now obtained a copy, and find that permanganate of potash is bracketed with Condy's Fluid, obviously inferring that it is one and the same article. It will be entirely to the point to quote from our correspondent's letter. He says:—"I take it from the advt. [?] that Condy's contains permanganate of potash." Certainly any reader would receive the same impression. Condy's Fluid does not contain any permanganate of potash. The *Lancet* has directed attention to and corrected a similar error, and has reported cases of death caused by permanganate of potash (see enclosed bill). Condy's Fluid being non-poisonous and innocuous is perfectly safe for all the uses for which we recommend it, and our interests are seriously affected by the damaging nature of this erroneous statement. We must therefore request you to correct the error in your next issue, and regret that the information did not reach us in time for the correction to appear in your last week's issue. *For Condy & Mitchell, Ltd., M. Locke.*

SCHEDULES RECEIVED.

CARDIFF AND DISTRICT CHRYSANTHEMUM SOCIETY'S 21st annual exhibition to be held in Park Hall, Cardiff, on Wednesday and Thursday, November 6, 7.

TONBRIDGE GARDENERS' AND AMATEURS' SOCIETY'S 84th annual Chrysanthemum and Fruit show, to be held on Wednesday and Thursday, November 13, 14, 1907, in the Public and Drill Halls, Tonbridge.

SOCIETIES.

ROYAL HORTICULTURAL Scientific Committee.

MARCH 19.—*Present:* Dr. M. T. Masters, F.R.S. (in the chair); Messrs. G. Massee, E. M. Holmes, A. Worsley, C. A. Hooper, G. Gordon, A. E. Bowles, J. T. Bennett-Poë, J. Douglas, G. S. Saunders, W. C. Worsdell, H. Güssow, and F. J. Chittenden (hon. sec.). Visitors: Messrs. J. Buritt-Davy and B. James, of British Guiana.

Diseased Violets.—Mr. MASSEE reported that the Violets sent to the last meeting were attacked by the fungus *Phyllosticta violæ*. "This and the disease due to *Cercospora violæ* are indistinguishable in their mode of attack, and can only be identified under the microscope. The primary cause of both diseases is excess of moisture and lack of proper ventilation during cultivation."

Gall on Oak.—Mr. HOLMES showed a gall from the common Oak, which Mr. SAUNDERS reported to be formed by the grubs of one of the Hymenopterous gall flies, probably by *Aphilotrix globuli*, one of the gall flies with alternating generations; these galls would produce *Andricus inflator*, whose grubs would form green globular galls surrounded at their base by the scales of the buds. *Aphilotrix globuli* is the sexual generation.

Curious Swelling on Stem.—THOS. SHARP, Esq., F.R.H.S., of Westbury, Wilts, sent a stem of Sloe (?) having at its upper end a curious knob-like swelling about 3½ inches in length and over 2 inches in diameter, marked very similarly to "bird's-eye Maple." This was evidently formed as the result of a wound, the healing tissue having given rise to a large number of adventitious buds, the small shoots from which had disappeared.

Cotyledon macrantha.—Dr. MASTERS reported that he had examined this plant shown at the last meeting, and found that it had been described and figured some time since, and showed no remarkable deviations from other plants of its genus. The proposal to award it a Botanical Certificate therefore fell through.

Agapetes speciosa.—A remarkable shrub with large red tubular flowers was shown by Mr. J. T. BENNETT-POE, which appeared to be a hitherto undescribed species of *Thibaudia*. Its native home was not known, as the plant had been found by Mr. POE in the greenhouse, and there was no record of its original source. The question of awarding it a Botanical Certificate was deferred until the plant should be named. [This has since been determined to be a new species of *Agapetes*, and a Botanical Certificate was awarded the plant on the ground of novelty and interest at a meeting of this committee held on April 2, a report of which will be printed in our next issue.—ED.]

Malformed Cyclamen.—Mr. WORSDELL reported that he had examined the *Cyclamen* shown at the last meeting, and had found small adventitious flower buds in the axils of the sepals with their parts greatly aborted. Mr. CHITTENDEN had sent him one showing similarly malformed growths, but in that the adventitious flowers had become well developed, although stamens were missing from some of them and so on. Although the buds were probably really axillary to the sepals, they had become laterally displaced owing to lack of room, so that they stood between the sepals. The whole presented the appearance of a large double flower.

Hybrid Orchid.—Mr. JAMES DOUGLAS showed an interesting hybrid raised by crossing the hybrid *Cymbidium eburneum* × *Lowianum* with *C. eburneum*. The resulting plant had flowers closely approaching *C. eburneum* in appearance and colour, but showing traces of *C. Lowianum*, particularly in the tinting of the column, the suffusion of yellow on the labellum, and the form of the double crest which runs down the labellum.

Asparagus Kale Dying.—Mr. S. T. WRIGHT sent specimens of *Asparagus Kale* from Wisley, which showed, on cutting sections across the stem, lattice-like openings in the woody tissue. These had been destroyed by the attacks of the bacterium, *Pseudomonas campestris*, well known on some parts of the Continent and in America. It is reported that the spores may be carried with the seed and the disease so propagated.

MEETING OF COMMITTEES ON APRIL 2.

APRIL 2.—Although the show on Tuesday last was held immediately after Bank Holiday, there was a good display of exhibits in the Hall. *Pæonies*, *Cinerarias*, *Hyacinths*, forced shrubs, early *Daffodils*, *Carnations*, and *Orchids* had a most brilliant effect. Novelties appeared fewer than usual.

The ORCHID COMMITTEE recommended one First-Class Certificate and four Awards of Merit; the FLORAL COMMITTEE one First-Class Certificate and two Awards of Merit; and the NARCISSESS COMMITTEE one Award of Merit.

THE FRUIT AND VEGETABLE COMMITTEE found little to do, one or two seedling Apples and a dozen varieties of late-keeping Apples, staged by Mr. W. STRUGNELL, Rood Ashton Gardens, representing all that was brought to their notice.

At the meeting of the FLORAL COMMITTEE, attention was directed to the trouble and inconvenience suffered by exhibitors, members of committees, and others by the holding of a meeting on a day following upon a Bank Holiday, and it was unanimously resolved to urge upon the Council the necessity for avoiding the selection of such a date in the future whenever it is possible to do so.

At the afternoon meeting nearly 50 new Fellows were elected, and Mr. H. J. Chapman exhibited about 100 lantern-slides, prepared from photographs taken by himself, showing *Orchid* species and their hybrids.

Floral Committee.

Present: W. Marshall, Esq. (chairman), and Messrs. George Nicholson, J. Green, R. Hooper Pearson, W. Howe, C. Bick, George Gordon, H. J. Cutbush, Chas. Dixon, C. E. Pearson, George Paul, W. Cuthbertson, E. H. Jenkins, W. P. Thomson, and Walter Ware.

A fine group of tree *Pæonies* (*Pæonia Moutan*) was shown by W. JAMES, Esq., West Dean Park, Chichester (gr. Mr. W. H. Smith). The plants were in 8-inch pots, and many of them had three, four, and even five very large flowers, which in some instances were 8 and 10 inches in diameter. In colour the flowers were of delightful shades of red, rose, purple, and white. They were extremely variable in form, being in some instances of quite the florist's type, with broad, rounded segments, but others were of more stellate appearance, and very attractive. The plants were received direct from Japan, and are unnamed. The exhibit was of unusual character, and exhibited first-class cultivation. (Silver-Gilt Flora Medal.)

Messrs. HUGH LOW & CO., Bush Hill Park, Enfield, exhibited a miscellaneous collection of greenhouse flowering plants and Ferns, some good vases of *Carnations*, an assortment of *Acacias*, a batch of the graceful *Phoenix Roebelinii* and pretty coloured *Cyclamen*. (Silver-Gilt Banksian Medal.)

Messrs. H. CANNELL & SONS, Swanley, Kent, made another very brilliant display with bunches of Zonal *Pelargoniums*, amongst which were interspersed bunches of Violets. One of the best scarlet-coloured *Pelargoniums* is *The Sirdar*, and a shade darker is *Duke of Bedford*. Mrs. Geo. Cadbury is a fine salmon shade. Adjacent to the *Pelargoniums* the same firm displayed a batch of the lax flowering or "stellata" *Cineraria*; the plants were well flowered, and representative of a very desirable strain. (Silver-Gilt Banksian Medal.)

Mr. H. B. MAY, Dyson's Lane Nurseries, Upper Edmonton, showed hardy Ferns in many choice plumose and crested forms, some neat plants of *Gardenias*, a few *Auriculas* and *Pansies*, and a large batch of the dwarf free-flowering *Roses White Pet* and *Mad. N. Levassieur*. As a separate group, Mr. MAY exhibited a semi-circular group of *Cinerarias* of the large-flowered type known as the giant strain. (Silver Flora Medal.)

Carnations displayed by Messrs. WM. CUTBUSH & SONS, Highgate, London, N., formed a very bright exhibit, popular varieties in the first-class quality being exhibited in excellent taste. Messrs. CUTBUSH also displayed an extensive array of rock-garden plants, with dwarf shrubs suitable for this style of gardening, and many varieties of *Tulips* in pots. (Silver-Gilt Flora Medal.)

Messrs. JAMES VEITCH & SONS, King's Road, Chelsea, S.W., showed greenhouse *Rhododendrons* of such choice kinds as *Lady Alice Fitzwilliam* and *Veitchianum*, a dozen large plants

of *Magnolia Soulangeana* (all heavily flowered), forced Lilacs, *Andromeda japonica*, *Hydrangeas*, and other flowering subjects, intermingled with which were pretty Maples and Ferns. As a table exhibit, the same firm displayed plants of *Azalea indica* that were pyramids of flowers; a fine batch of *Crowea angustifolia*, a group of *Primula kewensis* X, *Rhododendron Earl Gem*, &c. (Silver-Gilt Flora Medal.)

Messrs. R. & G. CUTBERT, Southgate, London, N., staged Hyacinths in circular batches of self colours, all grown in small 60-size pots, but nevertheless flowering in heavy trusses. The exhibit required almost the whole of two large tables for its accommodation. Gertrude (pink), King of Blues, and Schotel (pale blue) were among the best noticed. (Silver-Gilt Flora Medal.)

Mr. FRANK CANT, Colchester, showed Roses in boxes and vases, the most conspicuous being the orange-yellow coloured variety named after Lady Roberts. This was shown in really grand form, and other good flowers were Mrs. W. J. Grant and Mrs. Ed. Mawley. (Silver Banksian Medal.)

Mr. W. E. WALLACE, Eaton Bray Nurseries, Dunstable, again displayed the new American-raised Rose Richmond.

Miss DODGE, Guildford (gr. Mr. R. Stoward), showed 17 varieties of Violets that exhibited first-class culture. (Bronze Flora Medal.)

Messrs. RICHARD SMITH & Co., Worcester, showed balloon-trained plants of Clematis in many varieties and a few miscellaneous plants—Hepaticas, Saxifragas, Jasminum, *Azalea amœna*, Maples, &c.—interspersed among the Clematis. (Silver Flora Medal.)

Mr. L. R. RUSSELL, Richmond, Surrey, staged a large number of Clematis in pots, all well flowered, a number of showy *Rhododendrons*, and several forced flowering shrubs. (Silver Banksian Medal.)

Messrs. PAUL & SON, Cheshunt, Herts, displayed greenhouse varieties of *Rhododendrons* in small, compact, well-flowered specimens, also *Deutzia gracilis*, *Cytisus incarnatus*, and *Wistaria sinensis*. Two good *Rhododendrons* are Duke of York and Helen Paul, the latter a very pale, rose-blush variety. H. M. Arderne has large flowers of a rose-pink shade.

Mr. GEO. REUTHE, Keston, Kent, brought many interesting hardy flowers and trusses of handsome *Rhododendrons*. The charming little *Calypso borealis*, a terrestrial Orchid, was represented in the group, the specimen having two well-developed flowers. (Silver Banksian Medal.)

The Misses HOPKINS, Barming, Kent, exhibited some good-coloured Primroses, the pretty Daisy Alice, *Anemone Pulsatilla*, and other spring flowers, as well as tubers of *Tropæolum tuberosum*.

Messrs. BARR & SONS, King Street, Covent Garden, staged a group of Alpine and rock-garden plants, with several choice varieties of Daffodils and Hyacinths. *Anemone blanda* was a feature in the exhibit.

Mr. ROBERT SYDENHAM, Tenby Street, Birmingham, displayed bowls of Lily-of-the-Valley and bulbous flowers grown in moss-fibre without drainage to the pots.

THE HORTICULTURAL COLLEGE, Swanley, Kent (gr. Mr. Lawson), staged a batch of the yellow-flowered *Primula verticillata*.

Messrs. DOBBIE & Co., Rothesay and Marks Tey, showed Pansies, Violas, and Violets. The Pansies and Violas represented the very best of these old-fashioned flowers, the newest being Nancy Marsh, a variety of the richest colouring—a satiny blue-black, blotched with mauve. The Violets included 20 distinct varieties.

Messrs. JOHN PEED & SON, West Norwood, London, exhibited Alpine plants; and a small exhibit of these miniature plants was displayed by Messrs. J. CHEAL & SONS, Crawley, Sussex.

Several interesting plants were displayed by various exhibitors, the most interesting being a grand specimen in flower of *Doryanthes excelsa* shown by Lord ROTHSCHILD. The inflorescence, reared on a stout peduncle 12 feet or more in height, bore a corymbose head of dark-red flowers, and large green-coloured anthers. (Silver Banksian Medal.) A specimen of the yellow *Calla Elliottiana*, with a spatheous leaf at the back of the ordinary spathe, was shown by W. COBB, Esq., Normanhurst, Horsham (gr. Mr. C. Salter). Blooms of the rare flowering *Magnolia Campbellii* were shown from Sir

EDMUND LODER's rich gardens at Leonardslee (gr. Mr. W. A. Cook), together with a basket of the handsome *Rhododendron Fosterianum*. The *Magnolia* blooms were very large and cup-shaped; the colouring is a suffusion of vinous red on white—a most handsome species. (Silver Banksian Medal.)

FIRST-CLASS CERTIFICATE.

Rhododendron nigro-punctatum.—This is a species from China, having been collected there by Mr. E. H. Wilson. The plants are perfectly hardy, and, growing only a few inches high, are suitable for cultivation on the rockery. The flowers are about $\frac{1}{2}$ -inch in diameter, and they open almost flat. In colour they are a shade of Lilac. The leaves are of oval form, almost, or quite smooth on both surfaces, and not more than $\frac{1}{2}$ -inch in length. Shown by Messrs. JAMES VEITCH & SONS, Ltd.

AWARDS OF MERIT.

Hippeastrum "Vulcan".—This is a self-coloured flower of deepest maroon crimson, with a splendid "sheen" towards the centre. In form the variety is not so regular as some others.

Hippeastrum "Lady Howick".—In this variety we have a flower of the very best form, judged from the florist's point of view. The colour is rose-lake, but it is prettily mottled with white, and a broad white band extends along the centre of each segment. These varieties of *Hippeastrum* are among the choicest. Both were shown by Major HOLFORD, Westonbirt.

Narcissus Committee.

Present: Henry B. May, Esq. (chairman); Miss E. Willmott, and Messrs. J. T. Bennett Pöe, Joseph Jacob, W. F. M. Copeland, S. Eugene Bourne, P. Rudolph Barr, K. W. Wallace, W. T. Ware, P. D. Williams, A. Kingsmill, E. A. Bowles, W. W. Fowler, G. Reuthe, G. W. Leak, R. Sydenham, G. H. Engleheart, E. M. Crossfield, Chas. T. Digby, W. A. Milner, Chas. Dawson, John Pope, W. Poupert, James Walker, Chas. H. Curtis (Hon. Secretary).

Mr. CHAS. DAWSON, Rosemoran, Gulval, Penzance, showed the most interesting group of Daffodils; in fact, it may be described as a collection of novelties, and most of them were good things. A prominent plant was Marsh Light, with a fine orange-scarlet corona, and near by was one of pure white named Icicle, with hanging head. Merganser is a notable flower with large white segments and a cream-coloured trumpet. Chiquita has a white perianth and a beautiful sulphur-yellow trumpet. Open Face is of exquisite shape, and has an almost flattened corona of deep yellow, with a green "eye." Horace is a beautiful Poet's Daffodil, very rich in colour in its disc. Then there were Miss Mary, the large King Alfred, Gold-seeker, with perianth and trumpet of the deepest yellow, Phantom, Kittiwake, Sparkler, Pilgrim, Estelle, &c. (Silver Flora Medal.)

Sir JOSELYN GORE-BOOTH, Bart., Lissadell, Sligo, Ireland, showed a collection of many of the best of the standard varieties of Narcissi, including C. J. Backhouse, one of the finest of the incomparabilis type, Colleen Bawn, Incognita, Golden Bell (with beautiful yellow trumpet), Seagull (of the Leedsii type), M. J. Berkeley, Cernuus, and others of equal merit. (Silver Flora Medal.)

Messrs. POPE & SON, King's Norton, Birmingham, showed a small selection of popular varieties, such as Giant Waverin, King's Norton, Glory of Leiden, Southern Star, &c.

Messrs. CUTBUSH & SONS, Highgate, London, N., displayed a very large number of Tulips in pots.

AWARD OF MERIT.

Homespun.—A flower of exceptionally fine form, approaching the incomparabilis type. The perianth is pale lemon colour, with a deeper coloured cup. Shown by Mr. CHAS. DAWSON, Penzance.

Orchid Committee.

Present: W. Thompson, Esq. (in the chair), and Messrs. Jas. O'Brien (hon. sec.), De B. Crawshaw, Fred. J. Hanbury, H. Little, H. G. Alexander, W. H. Young, W. H. White, J. Charlesworth, W. Cobb, A. Dye, A. A. McBean, F. M. Ogilvie, W. Boxall, H. J. Chapman, H. Ballantine, H. A. Tracy, and C. J. Lucas.

NORMAN C. COOKSON, Esq., Oakwood, Wylam (gr. Mr. H. J. Chapman), staged a superb group, for which a Silver-Gilt Flora Medal was

awarded, and which contained some very remarkable varieties of *Odontoglossum crispum*. Two new unnamed blotched forms were generally admitted to be in advance of any yet shown in their respective classes. The one inflorescence carried a spike of five flowers, each of perfect form, and so heavily blotched with a peculiar-blended tint of purple, rose, and orange that the margins and some few intersecting lines only showed the silver-white ground colour; the other, with two very large and handsome blooms, was equally finely marked, but the heavy blotching was of a deep claret-purple, the area around the crest in each case being yellow. Among other fine *Odontoglossums* were the beautiful *O. Pescatorei Thompsonianum* (F.C.C., April 23, 1889), and still one of the best spotted *O. Pescatorei*; a very dark *O. Vuylstekei*, good *O. loochristense*, *O. Adriense*, &c. A feature in the group was the collection of *Oakwood Phaius*, one of the finest of which is P. Clive, which has in its composition three-fourths of *P. tuberosus*, the remaining fourth *P. Sanderianus*. The specimen of *P. Cooksonii*, which secured the Lindley Medal last year, was shown with nineteen spikes. The group also contained a very varied selection of *P. Norman*. Also a fine specimen of the rich magenta-tinted *Dendrobium Sibyl superbum* and other showy kinds.

J. BRADSHAW, Esq., The Grange, Southgate (gr. Mr. Whitelegge) was awarded a Silver-Gilt Flora Medal for a very fine group rich in rare varieties of *Cattleya Trianae*, specimens of the white forms which occupied the centre bearing collectively 39 flowers. The best of these were the varieties alba, Fairy Queen, Oberon, Vesta, and Osiris, the last-named having 10 fine blooms. The coloured varieties were also good: the best—C. T. Mooreana—is described under Awards. At the back of the group was *Cymbidium Lowianum* and good examples of the bright yellow *Oncidium concolor*; and in front was a fine selection of *Lycaste Skinneri*, including about 20 flowers of the white form. Of the *Cattleya Schroderae*, the variety W. Duckham had fine and unusually dark colour.

Messrs. ARMSTRONG & BROWN, Orchardhurst, Tunbridge Wells, secured a Silver-Gilt Flora Medal for a very remarkable group composed entirely of about 150 compact plants of the white *Dendrobium nobile virginale*, all raised from one seed capsule, and now developed into very pretty plants. As a variety for cut flowers it is of great merit.

Messrs. SANDER & SONS, St. Albans and Bruges, were awarded a Silver Flora Medal for a select group, in which noteworthy plants were *Odontoglossum ardentissimum inversum* Butterfly—a finely-formed flower thicker in substance and better in shape than the ordinary form, and of a clear silver-white, with light, purplish-rose blotching; *O. Wilckeanum* J. Gurney Fowler, a grand variety, with finely-formed, well-proportioned flowers about 5 inches across, and of a pale yellow tint, richly blotched with dark chestnut-brown; *Cattleya Schroderae* Gloire de Bruges, with pale, lavender-tinted sepals and petals, and a fine labellum that in front was of the rich, reddish-violet tint seen in some forms of *C. Percivaliana*; and *C. Trianae* Rex, the labellum of which was of a deep purple colour. The group also contained *Cœlogyne Lawrenceana*, a species introduced by Messrs. Sander from Annam, and which proves to be a fine new plant; *Zygopetalum Gottianum*, with purple sepals and petals, and a violet lip; *Schomburgkia undulata*, *Arpophyllum giganteum*, *Lycaste Skinneri* alba, and some pretty hybrid *Lælio-Cattleyas*.

Messrs. CHARLESWORTH & Co., Heaton, Bradford, received a Silver Flora Medal for an effective group, in which hybrid *Odontoglossums* were prominent. They included varieties of *O. Ossulstonii*, variable in tint, but always beautiful; *O. Rolfeae*, *O. amabile*, *O. Wilckeanum*, &c. Two forms of *O. Sylvia* (cirrosum X Rolfeae) were specially interesting as showing the great variation to be had from the same cross. The one had a cream-coloured ground spotted with claret colour; the other a bright yellow ground marked with purple—and how the yellow becomes so pronounced from such parentage is not easy to determine. Other plants noted were the bright scarlet *Sophræ-Lælia Psyche*, good *Odontoglossum crispum*, a dark *Lælio-Cattleya* *Dominiana*, *Brasso-Cattleya* *Digbyano-Mendelii*, *Miltonia Bleuana*, &c.

Messrs. JAS. VEITCH & SONS, King's Road, Chelsea, secured a Silver Banksian Medal for an interesting group, in which was their new hybrid *Cypripedium* Countess of Carnarvon (*villosum giganteum* x *Euryades*), a finely-formed and richly-coloured flower larger than *C. Euryades*, the broad dorsal sepal being rose-purple, with a broad, white margin; also *C. aureum* Hyeaum and other *Cypripediums*; *Cattleya Schroderae*, *Laelio-Cattleya highburyensis*, *Cattleya Trianae alba*, and, amongst others of its class, a singular hybrid, *Epi-Laelia Eva* (*E. aurantiaca* x *L. cinnabarina*). The plant shown had one narrow-petalled scarlet flower.

Messrs. MOORE, LTD., Rawdon, Leeds, showed a small group of *Dendrobium* nobile varieties, *D. Ainsworthii*, and other *Dendrobiums*, including a plant of the singular *D. Ruckeri*, *Angracum*, *Leonis*, *Dendrobium Wardianum*, &c. (Silver Banksian Medal.)

Major G. L. HOLFORD, C.I.E., G.V.O., Westonbirt (gr. Mr. H. G. Alexander), sent a cut example of the fine *Dendrobium fimbriatum* oculatum, Westonbirt variety, to which an Award of Merit was given in 1905; and *Laelio-Cattleya Baroness Schroder*, Westonbirt variety (see Awards).

C. J. LUCAS, Esq., Warnham Court, Horsham (gr. Mr. Duncan), showed a selection of *Laelio-Cattleya Lawrie* (*L.-C. Warnhamensis* x *C. Lawrenceana*) varying in colour from bronzy-orange to intense rose-purple, the best of which was selected for an Award of Merit.

Baron Sir H. SCHRODER, The Dell, Egham (gr. Mr. Ballantine), showed the fine and brightly-coloured *Odontoglossum Wilckeanum Schroderianum*.

J. GURNEY FOWLER, Esq., Glebelands, South Woodford, showed a brightly-coloured hybrid near to *Odontoglossum Hallio-crispum*. The flower is a bright yellow, blotched with chocolate colour, the lip being white with brown blotches.

The Rev. D. J. STATHER HUNT, Tunbridge Wells (gr. Mr. Baker), showed several plants of *Laelia Statherae* (*purpurata* x *flava*) varying from cream colour to primrose, with purple markings on the lip.

W. WATERS BUTLER, Esq., Southfield, Norfolk Road, Edgbaston, Birmingham, sent a fine example of *Cymbidium insigne* (Sanderi). One spike had 10 flowers, which were all good, although they had been open for a month; also *Odontoglossum Wilckeanum* "King of Spain," a very fine form of bright colour.

Messrs. LINDEN & Co., Brussels, sent two varieties of *Odontoglossum exultans* (excellens x *crispum bellatulum*), both good, yellow flowers finely blotched with reddish purple; *O. Jorisianum* (*luteo-purpureum regali* x *triumphans*); and a fine *O. crispum* (see Awards).

F. MENTEITH OGILVIE, Esq., The Shrubbery, Oxford (gr. Mr. Balmforth), showed a small promising plant of *Odontoglossum crispum Fergus*, with flowers of good form and having a considerable part of each segment of a light purplish-rose colour. Also *Cypripedium niveum Ajax* and *Cymbidium eburneo-Lowianum*, Shrubbery variety, with four spikes.

AWARDS.

FIRST-CLASS CERTIFICATE.

Laelio-Cattleya Baroness Schroder, Westonbirt variety (*L. Jongheana* x *C. Trianae*), from Major G. L. HOLFORD, C.I.E., G.V.O. (gr. Mr. H. G. Alexander). A very beautiful flower equal in size to the largest *C. Trianae*, and of fine substance. The sepals and broadly ovate petals are rose-pink, veined with a darker shade of the same colour, the whole surface glistening in the sunlight. The central portion of the lip is deep orange.

AWARD OF MERIT.

Laelio-Cattleya Lawrie (*L.-C. Warnhamensis* x *C. Lawrenceana*), from C. J. LUCAS, Esq. (gr. Mr. Duncan). A very brightly-coloured hybrid, with mauve-purple flowers and a maroon lip.

Odontoglossum Roi d'Angleterre, from Messrs. LINDEN, Brussels. A grand, blotched variety raised from seeds of finely-blotched *O. crispum*. The greater part of the surface of the well-formed flower was marked with large blotches of a light purple colour with an underlying orange shade.

Odontoglossum crispum album, "Orchid Villa" variety, from M. THEODORE PAUWELS MEIRELBEKE, Ghent. A charming variety of fine shape,

and snow-white, with a few orange-yellow blotches on the lip similar in tint to those seen in the variety *Xanthotes*.

Cattleya Trianae Mooreana, from J. BRADSHAW, Esq., The Grange, Southgate. A very handsome and distinct variety, with light, rosy-lilac sepals and petals, the latter bearing a claret-coloured "feather" at the tip. The lip is a deep, ruby-claret colour, with orange at the base. *Cattleya Trianae* is one of the most plentiful in gardens, but the leading fine varieties must always be rare.

THE LECTURE.

Mr. H. J. CHAPMAN, at 3 p.m., delivered a lecture on "Hybrid Orchids and their Parents," the remarks being illustrated by the aid of 100 coloured lantern slides, photographed from nature, and prepared by the lecturer. The lecturer's opening remarks concerned the species of *Phaius* of the Madagascar section, and he instanced the remarkable influence produced from the intercrossing of these with the Himalayan species. Among the different crosses of *Cypripedium*, perhaps the most interesting are those derived from the influence of the long-lost, but recently-re-discovered *C. Fairieanum*. *C. insigne Sanderæ*, when fertilised by its own pollen, produces itself true to its characteristics, but when crossed with some other kind, reversion takes place and the normal characteristics of the type species are produced. By continuation of inbreeding in this sport, taking a light-coloured offspring on each occasion and crossing it with the original *C. i. Sanderæ*, an albino is produced, in the third generation of inbreeding. White *Cattleyas* were also shown to illustrate reversion. Sometimes hybrid albinos have been produced from the influence of the albino species used in their parentage. Various other genera, including *Dendrobium*, *Odontoglossum*, *Cymbidium*, *Calanthe*, &c., were alluded to, and several slides showing crosses from them displayed on the screen. The advantages of home-raised hybrids from a cultivator's point of view is that owing to their greater vigour they can be kept in cultivation far longer than is found to be the case with imported species.

LINNEAN SOCIETY.

MARCH 21.—Prof. W. A. Herdman, F.R.S., President, in the chair.

Mr. W. Carruthers, F.R.S., F.L.S., exhibited on behalf of Mrs. Helen Ward, of Slough, a series of 19 drawings of Alpine flowers, grouped according to their time of flowering, and intended to illustrate a forthcoming volume.

Mr. J. Burt-Davy, F.L.S., showed 50 lantern-slides illustrative of the tree and bush vegetation of the Transvaal.

Mr. E. A. Newell Arber, F.L.S., then gave a summary of a paper, of which the following is an abstract:—

"On the Origin of Angiosperms." By E. A. Newell Arber, M.A., F.L.S., Trinity College, Cambridge, University Demonstrator in Palaeobotany; and John Parkin, M.A., F.L.S., Trinity College, Cambridge.

In attempting to trace the ancestry of this group, the authors commence by a survey of living Angiosperms with a view to determining which among them present primitive features, and also with the hope of arriving at some hypothesis as to the type of fructification possessed by the earliest members of the group. They dissent emphatically from the view generally held, and especially advocated by Engler, that the most primitive Angiosperms to-day are those with unisexual flowers, and without perianth, e.g., *Piperaleae*, *Pandanaleae*, &c. On the contrary, they urge the acceptance of a strobiloid theory of the Angiospermous fructification on the grounds that it is typically and primitively a diplosporangiate (hermaphrodite) cone with a well-marked perianth, and one in which all the organs were originally numerous, spirally arranged, and hypogynous. It is pointed out that some of these primitive features are still retained among members of the *Magnoliaceae*, *Ranunculaceae*, *Alismaceae*, &c. From such a cone, the authors would derive by reduction the apetalous, unisexual flowers.

The view is expressed that the "motive force," which called the Angiosperms into existence, was a radical change in the method of

pollination. The anemophily of the Mesozoic ancestors was replaced by entomophily (the latter being regarded as the primitive Angiospermous habit), and this resulted in a shifting of the pollen-collecting mechanism from the megaspore itself to the megasporophyll.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

MARCH 21.—Committee present: Messrs. E. Ashworth (Chairman); Thorp, Sander, Walmsley, Warburton, Williamson, Upjohn, Keeling, Leemann, Shill, Cowan, Cypher, Parker, Ashton, P. Smith.

There was a very good display of plants, and Silver-Gilt Medals were awarded to Messrs. A. WARBURTON, Esq., W. THOMPSON, Esq., and Messrs. J. CYPHER & SONS for meritorious groups. Messrs. CHARLESWORTH & Co., Bradford, were awarded a Silver Medal for a group.

Mr. W. BOLTON also exhibited a display of plants.

First-Class Certificates were awarded *Cattleya* x *Empress Frederick*, shown by Messrs. CHARLESWORTH & Co.; *Odontoglossum* x *Lambeauium* var. *Franz Masareel*, and *O. L. var. augustum*, both from the gardens of A. WARBURTON, Esq.

Awards of Merit were conferred on *Odontoglossum crispum* var. *grandiflorum* and *O. Rolfeae* var. "Empress Marie," shown by W. THOMPSON, Esq.; *O. Warnhamense* var. *Ebor*, *O. amabile* var. *purpurascens*, and *O. Cremona*, all exhibited by Messrs. CHARLESWORTH & Co.; *O. crispum* var. *Orion* and *O. c. Bertie*, both shown by A. WARBURTON, Esq.; *O. c. Arthurianum*, exhibited by Messrs. H. Low & Co.; *Laelio-Cattleya* x *Baroness Schroder*, from Messrs. CYPHER & SONS; and *Odontoglossum* x *Wilckeanum* var. *Urania*, shown by Messrs. J. W. MOORE, Ltd. P. W.

ROYAL BOTANIC.

MARCH 27.—The exhibition held by this society on the above-mentioned date was favoured by spring-like weather, and the attendance of the public was above the average at these shows. The great conservatory was gay with spring bulbous plants, and other seasonable flowers, such as *Clivias*, *Genistas*, *Camellias*, *Callas*, *Rhododendrons*, *Dicentra* (*Dielytra*) *spectabilis*, &c., whilst the gardens outside were bright with patches of *Crocuses*, *Scillas*, and other early-flowering plants. The corridor was filled with exhibits, the society itself contributing freely, and especially interesting was a large group of Economic plants from the collection at the gardens.

A very handsome group of forced flowering trees and shrubs was staged by Messrs. W. CUTBUSH & SONS, Highgate, London, N. The exhibit occupied the whole of the end of the conservatory adjacent to the corridor, and it was staged in excellent taste. A waved border of dwarf plants of *Azalea mollis* in various colours, with a band of *Pteris cretica*, formed a pleasing finish, the main subjects being *Lilacs*, *Viburnums*, *Rhododendrons*, *Spiraeas*, *Ribes*, ornamental Apples and Peaches, *Laburnums*, *Staphylea colchica*, and similar plants. As a separate exhibit the same firm displayed a very large number of *Narcissi* and *Tulips* in pots. (Gold Medal.)

Messrs. R. & G. CUTHBERT, Southgate, London, N., also staged a beautiful group of flowering shrubs and trees, intermingled with Ferns, Maples, and Palms. Bright patches of colours were furnished by plants of *Azaleas* of good culture, and above these were standard plants of *Lilacs*, *Cytisus præcox*, *Laburnums*, *Wistaria*, the dark-coloured *Weigelia Eva Rathke*, *Cerasus J. H. Veitch*, *Pyrus Malus floribunda*, &c. Amongst the *Azaleas* was a magnificent plant of the variety *Dr. Reichenbach*, and another interesting plant shown well was *Wistaria multi-juga*. Many hardy *Ericas* found a place in the front of the display. (Gold Medal.)

E. A. HAMBRO, Esq., Hayes Place, Kent (gr. Mr. Grandfield), staged a very large assortment of early garden flowers, with many Alpine and rockery subjects, similar to the display put up by the same exhibitor at the Horticultural Hall on March 19. *Auriculas*, *Primulas*, *Kalmias*, *Tulips*, *Daffodils*, *Scillas*,

and many others were in flower, and there were so pans of rare and choice Alpines not in bloom. Well-flowered plants of Rhododendrons *præcox* and Countess of Haddington are utilised as a background to the dwarfier objects. (Gold Medal.)

Messrs. BARR & SONS, King Street, Covent Garden, were awarded a large Silver Medal for display of bulbous and other spring flowers. The Narcissi were interesting, and the varieties included the famous white (or rather deep cream) Peter Barr, and the newer Mrs. G. H. Barr, with a slender trumpet, pale yellow in young flowers, but creamy white in those later. Hepaticas, Anemones, Hellebores, Fritillarias, and Scillas were also noticed.

Messrs. JOHN PEED & SON, West Norwood, London, exhibited pans of Alpine and rock-garden plants, of which the interesting *Saxifraga umbellata*, *Millia uniflora*, *Narcissus cyclaneus*, and a few others were in flower. (Silver Medal.)

C. DU CHAPPIN, Esq., Cape Colony, sent succulent plants which figured at the late Garden Exhibition, and Mr. BAYLOR HARTLAND, of Cairn, Co. Cork, showed a new Daffodil—*S. W. Baylor Hartland*—which was given an award. It is a yellow-trumpet variety, somewhat resembling, but scarcely equal to, Lord Nelson.

Messrs. HUGH LOW & Co.'s new Fern, *Nephrolepis Whitmani*, gained a similar distinction.

MARKETS.

COVENT GARDEN, April 3.

We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—Ed.]

REMARKS.—The first consignment of Australian Apples for the season arrived this week, and sold for satisfactory prices. Doubtless these will affect the sale of the Oregon Newtowns, which have been the principal dessert Apple in the market throughout the winter. There has been a good demand for vegetables of the choicer kinds for the Easter season. Cucumbers are now arriving in large quantities, and the finest samples can be bought at 4s. per dozen. Good Denia and Valencia Oranges are very scarce, although there is an abundance of the common ones, which are very cheap. Trade is much quieter this week. P. L., Covent Garden, Wednesday, April 3, 1907.

POTATOES.

Bedfords, 75s. to 90s.; Blacklands, 75s. to 80s.; Lincolns, 80s. to 95s.; Yorks, 80s. to 100s.; Dunbars, 90s. to 120s.; Scotch, 80s. to 90s.; Teneriffe, 10s. to 14s. cwt. Stocks are very diminished in many districts, and arrivals in the market for the past week have been small. Prices all round show an upward tendency. W. J. C. & S., Covent Garden, April 3, 1907.

COVENT GARDEN FLOWER MARKET.

The Easter trade, especially in cut bloom, was fairly satisfactory, but no exceptional prices were made, and even the value of *Lilium longiflorum*, which was expected to be scarce, fell rather than rose on Saturday morning. Callas realised a little more than I anticipated, but there were many unsold at closing time. Roses were down to very low figures, and Daffodils made only normal prices. Tulips were abundant, the value of "whites" advanced a little, but though a very large trade was done on Saturday, there was a large surplus of material at closing time. An unusual large number of private buyers were seen, and as few salesmen refuse to serve them it considerably interferes with the ordinary florists' sales. Business in cut flowers this week is very slow, and this morning (Wednesday) very large supplies were left unsold. The recent bright, sunny weather has hastened everything: there is a glut of Daffodils, and splendid quality Roses are offered at quite nominal prices. Lily of the Valley can be purchased in the streets at 3d. per bunch of 12 spikes, Lilliums, of which some good Candidums are seen, are down to very low prices, Gardenias are cheaper, whilst *Azalea Fielderi*, *Camellias*, and other short-stemmed flowers can be had in plenty.

POT PLANTS.

The market is now open every morning for the sale of pot plants, but not many growers are seen on the odd days. Spring flower roots are a leading feature. Pansies are very good, also *Violas*, *Daisies*, *Primroses*, *Polyanthus*, &c. Other hardy subjects are now growing out of their rough winter condition. Hardy shrubs, *Roses*, and *Climbers* of all sorts are well supplied. In flowering plants are now seen some very fine *Azalea mollis*; varieties of *A. indica* are also plentiful in all shades of colour, and the plants are quoted at low prices. White *Lilacs* are seen in well-flowered plants, also *Rhododendrons*, *Intermediate Stocks* are to be had in flower. *Mignonette* is very good from several growers. I find the best quality is making 12s. per dozen pots. *Erica Cavendishii* in well-flowered plants is seen, but I think this is not likely to be over plentiful this season. Some very good *Lilium Harrisii* were seen this morning, but the flowers were not exceptionally forward. *Spiræas*, *Cinerarias*, *Marguerites*, and *Zonal Pelargoniums* are all plentiful in well-flowered plants. In foliage plants there is not much variation; Ferns are improving in quality, but there are still some with soft fronds. Variegated *Funkias* are very pretty. Summer bedding plants in store boxes are now arriving from many sources; *Marguerites*, *Lobelia*, *Calceolarias*, *Verbenas*, *Fuchsias*, and dwarf *Marigolds* (*Tagetes*) are already seen in flower. A. H., Covent Garden, Wednesday, April 3, 1907.

DEBATING SOCIETIES.

GROYDON & DISTRICT HORTICULTURAL.—Mr. P. F. Bunyard, Kidderminster Road, Groydon, lectured before the members of this society, on Tuesday March 19, the title of his address being "Wild Nature in the Garden." The discourse was well illustrated with lantern views, and as each subject was shown Mr. Bunyard discussed on its merits and demerits, and in many instances described its life history.

WARGRAVE & DISTRICT GARDENERS.—On Wednesday March 20, Mr. W. J. Townsend, gardener to Sir Wm. Farrer, Sandhurst Lodge, delivered a lecture entitled "How to obtain a display of flowers in the open air from February to May," to the members of the above association. The lecturer's remarks were illustrated by a series of lantern slides of views in Sandhurst Lodge Gardens.

REDHILL & REIGATE GARDENERS.—Considerably over one hundred members of the above society were present at the meeting held on Tuesday, March 19, under the chairmanship of Mr. W. P. Bound. Mr. C. J. Salter gave a paper on "The Cultivation of the Chrysanthemum for Exhibition." The lecturer advised inserting the cuttings in December. Early October he considered the best time to house the plants, and they should then be placed in a temperature of about 50° to 52° Fahr. The lecturer gave a list of 24 selected Japanese, and 24 selected incurved varieties for exhibition. A good discussion followed the reading of the paper.

CATALOGUES RECEIVED.

ENGLISH.

S. MORTIMER, Swiss Nursery, Rowledge, Farnham, Surrey—Carnations, Dahlias, &c.
 E. P. DIXON & SONS, Ltd., Hull—Farm Seeds.
 Wm. CURTISH & SONS, Highgate Nurseries, London, N.—Hardy Plants, Dahlias, Roses, Verbenas, &c.
 W. WATSON & SONS, Clontarf Nurseries, Dublin—Garden Plants.
 HUGH LOW & CO., Bush Hill Park, Enfield, Middlesex—Carnations.

FOREIGN.

C. SPRENGER, Naples-Vomero, Italy—Interesting from its descriptions of new and rare plants.
 J. FRED WUSTENHOFF, Sassenheim, Holland—Dutch Bulbs and Flower Roots.
 V. LEMOINE & SONS, Nancy, France. Among the new plants are figured a Clematis-hybrid from C. Davidiana, Deutzia Vilmoriniana, Deutzia myriantha. A very interesting catalogue.
 SOUPERT & NOTTING, Luxemburg (Grand Duchy)—Roses.
 PETER LAMBERT, Trier, Germany—New Roses.
 LEVQUE & FILS, Ivry-sur-Seine pres Paris—Novelties in Fruits and Plants.

ANSWERS TO CORRESPONDENTS.

CAMELLIA: N. F. E. As you have not given any particulars as to the conditions in which your plant has been cultivated it is difficult to advise you. Assuming that the plant has suddenly become unhealthy it is probable that the roots have suffered from want of water or from the poverty of the soil, especially under the strain of flowering so freely as you have described. A large Camellia bush in a healthy condition requires copious supplies of water, and if the pot or tub is filled with roots occasional supplies of manure water are also necessary. If, on the contrary, your plant has gradually sickened, we should suppose the roots are dying from being water-logged or from the soil having become sour. Turn the plant out for examination, and if such is the case wash away all the sour soil, cutting away any roots that are found to show decay. For retubbing the plant use a mixture of turfy loam and peat, with plenty of sand and charcoal added. Cut away all unhealthy top-growth and place the plant in a warm plant-house, the better to induce it to make fresh growth.

CROQUET LAWN: A. R. The following is taken from the *Calendar of Garden Operations*, which can be had from our publishing department, price 7d., post free:—"For the purpose of playing the game of Croquet, a well-rolled level grass-plot or lawn not less than thirty yards long by twenty yards wide is required. A full-sized Croquet ground measures forty yards long by thirty yards wide. The following diagram will show what is needed:—

In the line through the centre of the ground, eight yards from the boundary at either end, put the Croquet pegs, and at sixteen yards from either end a hoop. Let the corner hoops be placed in a line with the pegs, and seven yards from the pegs.

CRICKETS: T. A. C. Place some Steiner's beetle paste about their haunts, spreading it on pieces of broken crocks. Crickets may also be trapped in garden mats, rolled and placed on the hot-water pipes.

CYCLAMEN: B. L. The name *C. latifolium* under which the plant was illustrated in the last issue is the correct appellation for *C. persicum*, which is not a native of Persia.

EMPLOYMENT AT KEW: H. D. Write to the Curator, Royal Gardens, Kew, Surrey, for a form of application, which you must fill up and return to him. Candidates must be more than 20 but under 25 years of age, and are required

to show that they have had five years practical gardening experience before entering Kew. The present wages are 21s. per week, sub-foremen receiving 27s. per week.

HYACINTH: H. S. The Hyacinths are gumming, caused by *Bacillus hyacinthi*. There is no known cure. All diseased plants should be burned and the soil in which they have grown should be disinfected with gas-lime.

LAUREL DYING: Mrs. K. The plant is affected with a fungus—*Fumago*. Grub up and burn the diseased plant to prevent the spread of the complaint.

MUSHROOMS: Reigate Mushroom Company. The Mushrooms are attacked by insects belonging to the family Poduridae and the genus Podura. These insects are commonly known by the name of "spring tails" owing to their habit of jumping away when disturbed. They were probably introduced with the spawn from Paris. It is doubtful whether they can be destroyed without destroying the bed. The Mushrooms would all, even the smallest, have to be collected and burnt and the beds soaked with some insecticide as paraffin emulsion, or the extract from 1 lb. of Quassia boiled for two or three hours in water and then diluted to make 10 gallons; or water at a temperature of 125° Fahr., or "Vaporite" might be mixed with the bed, but what effect these would have on the spawn we cannot say. The safest way would be to clear the whole bed out and thoroughly scald the interior of the house with boiling water so as to be certain to kill any of the pests which were left behind. The old bed should be burnt at once.

NAMES OF FLOWERS, FRUITS AND PLANTS.—We are anxious to oblige correspondents as far as we consistently can, but they must bear in mind that it is no part of our duty to our subscribers to name either flowers or fruits. Such work entails considerable outlay, both of time and money, and cannot be allowed to disorganise the preparations for the weekly issue, or to encroach upon time required for the conduct of the paper. Correspondents should never send more than six plants or fruits at one time: they should be very careful to pack and label them properly, to give every information as to the county the fruits are grown in, and to send ripe, or nearly ripe, specimens which show the character of the variety. By neglecting these precautions correspondents add greatly to our labour, and run the risk of delay and incorrect determinations. *Correspondents not answered in one issue are requested to be so good as to consult the following numbers.* **FRUITS: A. B.** The large Apple is London Pippin, and the small one should be sent us earlier another season.

PLANTS: F. I. *Ruellia Purdieana*. If you can spare a few cuttings for the Royal Gardens at Kew, they will be much appreciated, as the species is not in cultivation there.—*W. Notts.* Both varieties of *Odontoglossum Adrianae*.—*V. A. R.* 1, *Epidendrum ochraceum*; 2, *Trichopilia laxa*; 3, *Oncidium flexuosum*; 4, *Odontoglossum Lindleyanum*; 5, *Odontoglossum blandum*; 6, *Oncidium sphacelatum*.—*E. C.* 1, *Daphne Laureola* (Spurge Laurel); 2, *Kerria japonica* flore pleno; 3, *Narcissus moschat*.—*Orchid.* Both *Cattleya Schroderae*.—*G. A. B. & Co.* *Uniola paniculata*.—*A. B.* 8, *Erica hyemalis*.—*H. T. S.* 1, *Acer rubrum* or *dasyacarpum*; we cannot tell which without the leaves. 2, *Lonicera tatarica*. *S. R. A.* We cannot undertake to name varieties of Violets. 6, *Stauntonia latifolia*; 7, *Eriobotrya japonica*; 8, *Lonicera* species.—*N. F. B.* *Kennedya ovata*.

PELARGONIUMS: W. S. The Pelargonium roots are badly attacked by *Rhizoctinia*. The fungus lives in the soil, which should be thoroughly sterilised with gas-lime, as *Rhizoctinia* attacks all kinds of plants.

PLANTS SUITABLE FOR A CORRIDOR: J. H. K. The following plants are suitable for cultivation in a corridor in which the atmospheric temperature is never permitted to fall below 40°: *Fuchsias* in variety, *Daturas* (*Brugmansia*), with single and double white flowers, *Passifloras*, *Tacsonias*, *Begonia radicans* (scarlet), and other species, *Plumbago capensis* (blue), and *P. c. alba*, *Ipomaeas* in variety, *Cestrum* (*Habrothamnus*), *Lapagerias*, *White Jasmines*, *Abutilons*, *Clianthus Dampieri*, *Clematis indivisa lobata*, *Cobaeas*, *Kennedyas*, *Trachelospermum* (*Rhynchospermum*) *jasmynoides*, *Swinsonias*, *Hibbertia Cunninghamii*, *Psoralea bituminosa*, *Mandevilla suaveolens*, *Thibaudia acuminata*, *Solanum jasmynoides*, *Jasminum primulinum* (yellow),

Acacia Riceana, *Sollya heterophylla*, *Bougainvillea* and *Ivy-leaved* and *Zonal Pelargoniums*.

POTATOS: Eigob. The black patches on Potato leaves are not fungoid at all; there is no trace of mycelium and no evidence of Bacteria. It appears to be some purely physiological disease, possibly caused by local conditions which cannot be ascertained from inspection of the leaves alone.

SEWAGE WATER: E. L. We should not advise the continuous application of the undiluted sewage water to most plants, although it could be used in the case of coarse growing vegetables and Roses. Newly-planted trees and shrubs would be better watered with ordinary water, although they would benefit by applications of the sewage water at intervals, as indeed would most subjects, after they are established. Expose the fluid fully to the air in order that the harmful subjects present may be converted into food available for the plants.

SPANISH IRIS DISEASED: G. W. M. The plants are attacked by a fungoid disease. Dig up and burn the affected plants.

STOPPING OF TREE CARNATION SHOOTS IN ORDER TO HAVE FLOWERS AS EARLY AS NOVEMBER 1: Inquirer. Most cultivators cease to stop the earliest plants at about July 1. An excellent cultivator informs us that for two years past he has not stopped his plants at all until they are established in 5-inch pots and have attained a height of 8 or 9 inches. Thus treated the plants produce a greater number of strong shoots than previously when stopping was commenced when they were 6 inches in height and growing in 3-inch pots. The strongest shoots are again stopped when they are 4 inches in length, but the earliest plants are not stopped after the last week in June, or at the very latest the first week in July.

VARIETIES OF DOUGLAS FIR: A. E. M., Ireland. (a) No. 1 is a close-growing form approaching *Pseudotsuga Douglasi* var. *brevisfolia*, of which it is probably a seedling. No. 2 is typical Douglas Fir. Nos. 3 and 4 are both *P. D.* var. *glauca* (the Colorado Douglas Fir), and, though differing somewhat in general appearance now, it will be difficult to detect any differences between them in two or three years' time. (b) What is the reason of the Douglas Fir remaining practically at a standstill for several years and then either dying or growing away fast? Several reasons have been assigned, but the primary cause is an unbroken subsoil that the roots cannot quickly penetrate. The subsoil may be of clay, gravel, chalk, &c., and the trees will grow satisfactorily until they reach it, but afterwards they become stunted and poor through being starved. If the upper soil is shallow and dry, a dry season may kill the trees, but if they survive until the subsoil has been penetrated the subsequent growth is rapid and strong. The Douglas Fir will not, as a rule, succeed on chalk, but if there is a good depth of soil above the chalk, and the latter is not too deep, the trees will thrive after the calcareous layer has been penetrated by the roots. On land which contains a considerable depth of chalk the Douglas Fir should be planted experimentally at first. (c) How can the Oregon and Colorado varieties be distinguished when in a young state? In the seedling stage it is difficult to give particulars of any distinction between the two, except in colour, the Colorado variety being of a grey or blue tint against the green of the other. When the plants have attained a foot or more in height the leaves of the Colorado variety are stiffer and harsher to the touch, of a pronounced grey to blue colour, and either point forward towards the growing point or curve somewhat. In the Oregon variety the leaves are green, soft to the touch, closely set together and nearly or quite at right angles to the stems. They are also more regularly arranged in the latter than in the former variety.

COMMUNICATIONS RECEIVED.—F. Street (many thanks for 8s. which has been placed in the R. G. O. F. box) G. W. D. Zomba, B. Central Africa—Sir D. Morris, Barbados—A. B. R.—A. H. S., Johannesburg—W. SUMMER IN BRITISH CENTRAL AFRICA.

IT is one's first Christmastide, 'neath Afric's sky. The rains are general and the sun is but a few degrees from the vertical at noon. The thermometers are registering over 90° Fahr. in the shade, dropping to 75° at night. The temperature in the sun is between 150° and 160°, and the atmosphere close and humid. Spending many hours daily in the open, directing clearing and planting operations by brainless natives, or worse, working in an iron-roofed crematorium-like office, does not tend to improve health or temper.

The rolling plains—only recently one vast blackened mass of vegetation, justifying the phrase, "Darkest Africa"—are now changed as by a wizard's wand: the trees have sprouted in all the vivid colours of early leaves, and are already assuming more sober shades of russet, red and green; and one instinctively longs to go forth and explore nature's display, especially as the eye rests on Mlanje's rugged mountain, nearly 50 miles away across the plains. Early in the morning the lower slopes are hidden by dense banks of cloud, the higher peaks only, rising to nearly 10,000 feet, being visible. As the sun ascends so does the vast bank of cloud, to remain over the range—perhaps enveloping the higher peaks—like a vast fleecy mantle, during the heat of the day.

The usual method of travelling is to be carried

by natives in a hammock. This is an extremely slow mode of progression, especially to one living a year ago on the outskirts of the vast city of motors, tubes, and trams; and it is decided to proceed on a bicycle, the road or path being tolerably good in most places. A start is made at 5.30 a.m., in order to be well on the way ere the sun gets high. The air is fresh and cool, the grass delightfully bedewed: a general mist is spread over the plains, and, momentarily forgetting modern discoveries, which show that mosquitoes and malaria are as cause and effect, we look on it as the "white-death mist," or malarial miasma.

The country through which the road passes is one of countless trees. Leguminous species predominate, and the majority are small trees, rarely more than 30 feet high, or over 1 foot in diameter, never thick enough to shade the ground to a great extent. There are hundreds of *Pterocarpus melliferus*, a noble tree 50 to 80 or even 100 feet high, heavily loaded with Laburnum-like flowers. Cassias of all sizes from the dwarf annual stemmed *C. Tora* to the tall *C. abbreviata* add to the displays of yellow. Extremely beautiful is *Bauhinia Petersiana*, a small tree with broadly bifid leaves, and terminal corymbs of numerous flowers, with linear-lanceolate, fringed petals, which are pure white, and arranged in a spreading manner—in every way a most ornamental subject.

In every patch of damp, shaded soil, cobalt-blue, yellow, and white *Commelinas* are ever ready to cheer the early traveller, and him only, their delicate flowers being withered long before noon. Delightful to the eye are countless *Crinums*, probably *C. subcernuum*, displaying their large delicate pink flowers in marshy soils, but almost intoxicating one with the superabundance of their perfume. Specimens of *Hæmanthus multiflorus*, carrying over 100 crimson flowers in a head, are seen from time to time, and *Hypoxis villosa* spreads its yellow stars everywhere in the grass, whether in the plains or on the mountain. The poisonous *Buphane disticha* has ripened its seeds, and one notes a possible reason for its numerous long-pedicelled flowers being so disposed as to form a perfectly globular umbel. The breeze detaches the dry umbel from its support, and it goes rolling along a bare part of the plain for perhaps 200 yards ere it becomes entangled in a spinous *Acacia*, having meanwhile distributed the bulk of its seed in its path.

Here, under a denser forest growth, the ground is studded with what looks like terrestrial *Cattleyas*. One large purple-red flower turns out to be *Kæmpferia æthiopica*, with single blooms produced close to the ground in advance of the leaves. Another producing several smaller rosy-pink flowers on one stem is *K. rosea*. Most beautiful of all, however, is the allied *Cadalvena* (*Kæmpferia*) *spectabilis*, with enormous golden yellow flowers, suggesting in both shape and size some of the finer large-lipped hybrids obtained from *Brassavola Digbyana* and the larger *Cattleyas*. They are generally produced in twos and threes, contemporaneously with, or subsequent to, the four leaves, which, when developed, lie close along the ground.

Gloriosa superba is very common—its flowers are of every shade from yellow to crimson, according to their age. This plant rarely takes on the climbing, twining habit so familiar to gardeners, its stems being generally only 3 or 4 feet high, and quite erect. Few terrestrial *Orchids* are plentiful enough to make their presence noteworthy: exceptions occur in the case of *Lissochilus Wakefieldii*, with tall spikes of numerous yellow flowers, and *L. arenarius*, with fewer, but larger purple flowers, both species being met with all over the Shire Highlands. The showy *L. Horsfallii*, with purple, pink, and green, and *L.*

Sandersonii, with nearly white flowers, are fairly common.

Wherever a large ant-hill occurs, it is sure to be monopolised by huge, weird, candelabra-like *Euphorbias*. Occasionally a specimen of *Hyphaene crinita* is passed. This tall fan-leaved palm, not unlike *Borassus flabelliformis* in appearance, is, however, much more common away on the brackish shore of Lake Shirwa. Our prevailing palms a species of *Raphia* found in abundance along the banks of most of the smaller streams. It is most graceful, remaining stemless during the greater portion of its life, the numerous pinnate leaves, the mid-ribs of which are bright orange, reaching a height of 30 or more feet. When a trunk develops, the plant produces seeds in abundance, and rapidly decays. The seeds in appearance are not unlike some conifer cones, being covered with glossy, bronzy, extremely hard scales. The mid-ribs of the leaves are very useful, being light, strong, and of fairly uniform girth. They are especially used as rafters for houses, and for making ladders, scaffolding, &c.

A river, large and deep, is reached, which a month ago was waterless: the journey is more than half completed, and a long halt is made for rest and refreshment. The banks are heavily timbered with fine specimens of the valuable African mahogany, *Khaya senegalensis*, *Albizia anthelmintica*, and countless lesser trees and shrubs. *Gardenia Thunbergia*, a tree 15 feet high, is covered with its creamy white, salver-shaped flowers, at least 3 inches in diameter. *Landolphia Kirkii* and *Strophanthus Courmontii* are clambering from tree to tree, both in fruit, the former large, lemon-shaped, containing a quantity of delightfully cooling acid pulp, and the latter displaying its feathery, poisonous seeds, enormous quantities of which, belonging to another species (*S. Kombe*), are annually exported to the drug markets from this Protectorate. *Acacias*, *Cassias*, *Caesalpinias*, and *Mimosas* are striving to gain a footing among the dense vegetation, and the lower sunny branches are smothered with showy *Momordicas*, *Cucumbers*, *Lagenarias*, *Luffas*, and other *Cucurbits*, a variety of gay orange *Thunbergias*, and a bewildering variety of *Ipomœas*. High up in the forks of the trees there are clumps of an *Ansellia*, exposed to full sunshine; and much lower a profusion of the mistletoe cactus (*Rhipsalis Cassytha*), the only known Cactaceous plant not confined to the American continent (in an indigenous state); *Opuntias*, now a pest in many tropical countries, having in every known case, been introduced by man. Growing near the river is a fine specimen of *Kigelia pinnata*, the "sausage tree," at present covered with its racemes of large, blackish crimson *Bignoniaceous* flowers, the fruit which succeeds them being shaped like a *Luffa lufa*, but considerably larger: often as thick as a man's thigh.

Farther on, one crosses a marshy swamp that stretches for miles to right and left, dotted with many clumps of a tall, graceful, dark green *Phoenix* sp. (*reclinata*) (?); acres of *Phragmites communis*, now devoid of the snowy plumes; patches of *Cyperus papyrus*; and in deep pools a show of *Nymphæa stellata*, such as no brush or pen could justly describe; innumerable in quantity, in size varying from tiny 3-inch "stars" to huge 12-inch "planets," of every shade of colour from white to pink, and white to deepest azure blue. Many other interesting and showy things are there, but it is impossible to pay any attention to them after once having seen the *Nymphæas*, and one reluctantly passes on.

At last the only European's house between Zomba and Mlanje is reached, at the base of the mountain. The occupier is a lonely and most hospitable planter, whose nearest neigh-

bour lives 20 miles farther on. His trials are many. The labour supply is getting worse than ever; he has only a few boys and old women to work an estate of 700 acres. Things meteorological were never so badly arranged as this season (they have never been good); during all the rainy season he has not had one dull, showery day to enable him to transplant his coffee, tobacco, &c.; all rain having come at night in 3-inch instalments, followed by days of bright, blazing sunshine. A stroll is taken around the well-laid-out plantation. Cotton is the chief crop, and, owing to being planted early, the occurrence of warm weather, and no lack of rain, American, Egyptian, and Sea Island varieties all look very promising. Coffee is backward, having been badly crippled by the rains ceasing two months earlier than usual last season, followed by a severely dry season. A small plantation of Mauritius hemp (*Furcraea gigantea*) could not possibly be more thriving, and planters in general are beginning to recognise that fibres of this type are a sound investment in British Central Africa. Small areas of sugar cane, Ceara rubber; a well-kept kitchen garden, in which most European vegetables are successfully grown; Oranges, Peaches, Papaws; a magnificent avenue of Lemons over 500 yards long, always in fruit; a very heavy crop of Mangos, and a herd of over 300 high-class cattle are other interesting features. Mention might also be made of two "baby baobabs" (*Adansonia digitata*), only a few years old, yet already "swellin' wisely," and the pride of their owner.

ASCENT OF THE MOUNTAIN.

Starting in the morning, ere the sun is risen, to climb the rugged mountain, one travels along a gradually rising path for two miles, passing through large belts of Bamboo thicket, now delightfully fresh and green. Frequent in these thickets is *Cussonia Kirkii*, a tall shrub or tree, with Aralia-like leaves; also large trees of *Erythrina tomentosa*, whose thousands of bright crimson flowers are produced on the leafless trees in the dry season. The path is overgrown, and one has to walk warily to avoid being tripped up by the disagreeable *Mucuna pruriens*. This twining leguminous plant is quaintly pretty when in flower, but later its velvety fruits become covered with short, silky hairs, detachable by the least shaking, and woe unto him who is unfortunate enough to come into contact with it. A painful irritation is set up, and one instinctively flies to the nearest stream for relief. Occasionally one steps on the stems of *Paederia foetida*, whose disagreeable perfume can only be "appreciated" by those who have become acquainted with it in the Kew Palm-house.

Here the path runs alongside a rushing, tearing mounting stream that, rising 3,000 feet above, has torn madly on its downward course, in a series of cascades and cataracts, over erect cliffs and among enormous boulders. Along the banks many Eucalyptus-like trees of *Eugenia cordata* are in full bloom, *Dracæna fragrans* and screw Pines are scattered here and there along with the stately *Cyathea zambesiaca*, and luxuriant plants of *Marattia fraxinea*, from 6 to 15 feet in diameter. Now and then one finds, half-hidden behind huge boulders, a fine large *Encephalartos*, that for regularity of outline might almost have been designed and made on geometrical principles. *Osmunda regalis* occurs in every nook of damp, black soil, reminding one of the enormous clumps to be found even now in the wild valleys of North Cornwall. The overhanging banks are profusely clad with various other Ferns including numerous *Aspleniums*, *Nephrolepis cordifolia*, *Adiantums caudatum*, *æthiopicum*, and *lunulatum*, *Gleichenia dichotoma*, *Actinopteris radiata*, &c. Interspersed among these are numerous *Streptocarpus*, including *S. caulescens*, *Cooperii*, and probably *S. Galpinii*, all throwing up plenty of bright blue flowers, the leaves being closely adpressed to the vertical rocks, reminding one of

the position *Ramondia pyrenica* assumes in its favourite haunts. Farther on, some *Vitis* species are at the flowering stage: it will be interesting to determine them later on, and to ascertain their suitability or otherwise, as stocks for grafting with varieties of *V. vinifera*, which, upon their own roots, are not at present a success. A patch of *Orobanchæ cernua* is remarkable, not only for the size of the spikes of light-blue flowers, but for their number, there being over 100 in a space less than one square yard, the host plant is a species of *Tephrosia*. Showy, large, purple-red *Dissotis* are beginning to flower, and will be found at all elevations for the next six months, the principal species being *eximia*, *incana*, *Johnstonii*, and *Mellerii*. Their flowers closely resemble the closely allied and more familiar *Tibouchinas* of gardens.

Now an almost vertical wall of rock is reached; no path is possible, the only support provided being tussocks of grass collected here and there in the crevices, forming a scanty support for hand and foot. Progress is slow, but one is compensated by the leisure one has for studying the interesting occupants of every crevice, nook and cranny, and by the climate gradually becoming more bracing. Aloes, if poor in variety, are plentiful, the two common species being *A. Buchananii* and *A. abyssinica*, both now out of flower; also flowering specimens of the peculiar *A. cryptopoda*, a species that is here deciduous, the long spotted leaves not unlike those of *A. Cooperii* dropping off in the dry season, when it is impossible to find it, there being no visible stem. *Kalanchoe coccinea* is in full bloom, also *Bryophyllum calycinum*, several species of *Crassula*, and in small pools and rivulets a *Tillæa*, apparently *T. aquatica*. *Selaginella Kraussiana* is once more displaying its delicate traceries; showy *Moschomas*, *Plectranthus*, and *Lobelias* of the deepest blue make bright every accumulation of moist soil. Reminiscent of happy botanising rambles over the chalk downs of Surrey is the frequently-occurring *Scabiosa columbaria*. Gay species of *Coleus*, *Salvia*, and *Senecio*, *Kalanchoe platysepala*, *Gomphocarpus racemosus*, *Habenaria Wellerii*, *Adiantum Capillus-Veneris*, *Gleichenia dichotoma*, *Pellæa consobrina*, dwarf succulent *Euphorbias*, *Asparagus plumosus*, *Drimis robusta*, *Bulbine asphodeloides*, *Ornithogalum Ecklonii*, *Cyrtanthus Welwitschii*, *Urginea altissima*, and many other bulbs have their little nooks to fill. At last the summit of the cliff is reached, and one pauses in a delightful health-giving atmosphere at an elevation of 5,000 feet. *E. W. Davy, Agricultural, Forestry, and Botanical Department, Zomba, British Central Africa.*

(To be continued.)

ORCHID NOTES AND GLEANINGS.

ODONTOGLOSSUM MULUS.

A VERY pretty form of this natural hybrid is in bloom in the gardens of Leopold de Rothschild, Esq., Gunnersbury Park (gr. Mr. Geo. Reynolds). The specimen bears two branched spikes of many flowers. The variety was illustrated in the *Gardeners' Chronicle*, January 2, 1886, but it has never been plentiful, as in the case of *O. Andersonianum*, and some others. The form at Gunnersbury Park seems to bear out the suggestion that it is a natural hybrid between *O. gloriosum* and *O. luteo-purpureum*, for it has the odour and the markings on the petals as in *O. gloriosum*, although the broader expansion of the lip and its crest indicate the influence of *O. luteo-purpureum*. The sepals are pale yellow, with from three to four large sepia-brown blotches; the petals are also pale yellow, with reddish-brown markings at the base, and one large irregular sepia-brown blotch in the middle. The lip is white, with a brown blotch in front of the light yellow crest.

The *Odontoglossums* generally are in excellent condition, and some *O. crispum*, *O. Andersonianum*, *O. cirrosum*, *O. Pescatorei*, *O. Coradinei*, a very fine *O. Adrianæ*, and others are in bloom, together with a number of good specimens of the best scarlet *Sophronis grandiflora*, some of them bearing over 20 flowers each. *J. O'B.*

DENDROBIUM NOBILE.

I AM enclosing a photograph [not reproduced—Ed.] of a plant of *Dendrobium nobile* in these gardens, bearing over 200 flowers. It has been grown in the same pot (size 24) for the past 14 years without once having been re-potted, and it is now some 10 years since it was even top-dressed.

During all these years it has been placed in a small lean-to stove, close to the wall. After it has fully developed its growths, water sufficient only to prevent the pseudo-bulbs from shrivelling is given at the roots. I remove the old flowering growths every year after they have finished flowering. I do not know whether the length of time this plant has been grown without re-potting constitutes a record, but it certainly proves that an Orchid can be kept for a great number of years in good health without being pulled to pieces. *H. E. Hatto, Walsingham Gardens, Chislehurst.*

NEW OR NOTEWORTHY PLANTS.

AGAPETES SPECIOSA, HEMSLEY.*

(See fig. 101, p. 237.)

At the meeting of the Royal Horticultural Society on March 19, Mr. Bennett-Poë exhibited a specimen of a very handsome crimson-flowered *Agapetes* from his garden at Cheshunt, where he has had it growing about ten years. Two years ago it flowered, but it was not identified. The specimen was given to Kew for figuring in the *Botanical Magazine*, but as the figure cannot appear for some months, it was held to be desirable to publish the description at once, especially as the plant attracted much attention at the show, and a name was wanted for it. [A Botanical Certificate was awarded to Mr. Poë for this plant at the meeting of the Scientific Committee of the R.H.S. on April 2 on the ground of novelty and interest.]

The native country is unknown, but it is probably from Burma. There is, however, nothing quite like it in the Kew Herbarium. The nearest is a specimen named *A. setigera* var. *Roylei*, by the late C. B. Clarke, but that has leaves with a wedge-shaped base, smaller flowers and oblong calyx-lobes. The flowers are much more like those of the old *A. macrantha* in shape, but deep crimson, and the corolla-lobes are much less recurved, and the leaves differ also in the auricled or subcordate base. The leaves of *A. speciosa* are clustered at the end of each year's shoot, and the flowers are clustered in their axils. *W. Botting Hemsley.*

* *AGAPETES SPECIOSA, Hemsl.*—Species nova, inter affines *A. setigera* var. *Roylei*, C. B. Clarke, proxima, a qua foliis majoribus basi auriculatis, floribus majoribus et calycis lobis deltoideis brevioribus differt. *Frutex* paucipedalis, omnino glaberrimus. *Folia* alterna, pseudoveriticillata, brevissima crasseque petiolata, crassa, coriacea, fere horizontalia, ovato-oblonga, 8-10 cm. longa, 3-5 cm. lata, basi subcordata, bullata, obscure callosodenticulata, denticulis inter se circiter 5 cm. distantibus, supra saturate viridia, subtus pallidiora, utrinque subnitida; costa crassa, subtus elevata; venæ immersæ, inconspicuæ. *Flores* carnosæ, speciosæ, saturate rubro-sanguineæ, nitidæ, in foliorum axillis fasciculatæ; pedunculi breves, crassissimi, 3-6 flori; pedicelli carnosæ, 2-5-4 cm. longi, bracteæ bracteolisque minutis caducissimis. *Calyx* cum pedicello apice incrassato articulatus, persistens, circiter 5 cm. longus; lobi deltoidei, erecti, acuti, quam tubus breviores. *Corolla* tubulata, medio ventricosa, cum lobis 3-5-4 cm. longa, medio 1-5 cm. diametro, conspicue 5-costata; lobi lanceolati, obtusiusculi, erecti vel demum recurvi, circiter 1 cm. longi. *Stamina* 10, inclusa, filamentis brevissimis puberulis; antheræ biloculares, basi calcaratæ, loculis in tubulos elongatos angustissimos conniventes rimis debicentes productis. *Ovarium* 10-loculare, stylo lobulato breviter exserto. *Fructus* mihi ignotus.—*Patria ignota.*

MARKET GARDENING.

TOMATOS.

TOMATO plants under glass, planted in rows from 22 to 24 inches asunder and at 1 foot from plant to plant in the row, should have plenty of fresh air admitted to the structure on all favourable occasions in order to promote a sturdy, short-jointed growth in the plants and the development of flower-trusses on the stems pretty close to the ground. To the Tomato grower—whether under glass or out of doors—who obtains the first truss of flowers close down to the ground on the individual plants, it is a matter of pounds sterling on the right side. The pinching out of all side shoots as soon as they appear on the stems of the several plants is essential in order that the entire strength of the plants shall be concentrated in developing the crop. With this object in view the leaves should be cut back to two leaflets before they become crowded. As soon as the plants have attained to a height of 12 or 15 inches they should be afforded support in the nature of string made from a soft substance and known in the trade by the name of Tomato string. This being tied loosely round the stems of the individual plants close to the ground line and fastened to the wires overhead, or where these are not provided to $\frac{1}{4}$ -inch tin tacks driven into the sides of the rafters at from 13 to 15 inches apart, according to the angle of the roof; twining the single-stemmed plants round the strings as they increase in upward growth is all that is required in this direction. The soil in which the plants are growing must be kept uniformly moist, and should a surface-dressing with half-rotted manure be laid on between the rows to the thickness of between 1 and 2 inches it will add considerably to the weight and quality of the crop. This mulch, however, should not be laid on until the plants have set a couple of trusses of fruit each, otherwise the effect would probably be the opposite of that desired. *H. W. Ward.*

TREES AND SHRUBS.

COTONEASTER ROTUNDIFOLIA.

By far the most effective species of Cotoneaster throughout winter in the Royal Gardens at Kew is this species, for while the berries of other species are taken by birds very soon after they ripen, the fruit of *C. rotundifolia* is left alone until well on into the late winter months. Why birds refuse this for so long a period is a mystery, but the same thing occurs each year. Like many of the most ornamental Cotoneasters, this is an Himalayan shrub, and thrives almost anywhere in this country. It grows to a height of 4 or 5 feet, and furnishes itself well, but never becomes such a dense thicket as *C. buxifolia* or *C. horizontalis*, consequently the fruits are seen to advantage. The leaves are roundish and semi-evergreen, being often retained until well on into February. The fruits are as large as a good-sized Pea, very freely produced, and bright red in colour. For a sunny position in light, loamy soil it will be found a capital plant, while it also thrives in less favoured aspects. Cuttings of half-ripe wood in summer root readily, and a stock of plants can soon be raised suitable for permanent positions. *W. D.*

PHOTINIA SERRULATA.

In reply to "H.W.," p. 223, I may state that no damage has been done by frost this season to the young growths of this shrub in our district, and I question whether this plant is really as tender as it is commonly believed to be. We have a large specimen in a somewhat exposed situation (although it is against a wall), and another smaller plant growing on a sloping bank. They are both doing well, and have young growths upwards of 6 inches in

length. We have had considerable frost this winter—the lowest temperature reached being 11° Fahr. on December 30, whilst on March 12 it was down to 21°; many plants have suffered more or less, but the Photinias look much the same as they usually do at this season of the year. I only remember these plants being damaged once in the past thirteen years, but they quickly recovered, that was in 1895, when a minimum temperature of 3° below zero was registered on February 8. This shrub is worthy of growing for its fine, bold foliage, and for the rich, brown tint of the young shoots, which always start into growth early; its flowers are not freely produced, and are of no great beauty. *W. H. Divers, Belvoir Castle Gardens, Leicester-shire.*

—This evergreen is flowering here in the open garden for, I believe, the first time, although it has been in its present position for over sixteen years. The terminal inflorescences began to unfold long before Christmas, and we quite expected the flowers to expand about the end of February, but even now (April 5) no expanded flowers are visible. This appears strange, after reading of its flowering in Surrey so early in the year. *J. Mayne, Bilton.*

NOTICES OF BOOKS.

INDIAN TREES, &c., by Dietrich Brandis, K.C.I.E. London: Archibald Constable. 8vo., pp. 767, figs 201.

IN the title page to this volume Sir Dietrich Brandis briefly indicates the nature of its contents by stating that it is "an account of trees, shrubs, woody climbers, Bamboos and Palms indigenous to or commonly cultivated in the British Indian Empire." When we consider the vast extent of the Indian dominions, their varied elevations and climate from the Arctic snows of the Himalayas, the saturated Khasya Hills, the dry regions of Sind and Rajputanah, the swamps of the Sunderbunds, the mangrove thickets along the coast, and tidal rivers, we can form some idea of the magnitude of the task undertaken by the author. Sir Dietrich had, nevertheless, special facilities for the execution of his task. His lengthened service in various parts of India, his highly successful organisation of the forest-service, his relations with forest-officers in all parts of the Peninsula and Burma, have given him unrivalled opportunities. His personal endowments as an administrator and a botanist have enabled him to make the best use of these opportunities. He has had the willing assistance of his pupils and brother officers, whose aid he courteously acknowledges. Without the *Flora of British India*, edited and very largely composed by Sir Joseph Hooker, Sir Dietrich's task would have been even more laborious than it has been, and without the collections at Kew, the compilation of the volume would have been well-nigh impracticable.

It is, however, impossible to turn over the pages of this volume without a feeling of admiration for the skill and knowledge displayed by the author and of wonder at his long-continued, indefatigable powers of work and research. Over 4,400 species are described and classified in such a manner as to facilitate the work of forest-officers and others in the identification of the trees and shrubs they meet with. The internal structure of the timber and the details necessary to be known in order that the forests may be efficiently and economically managed are, relatively speaking, only lightly touched on in this volume. Many similar ones would be needed to contain all the details the practical forester and woodman requires. In the meantime Mr. Gamble's valuable *Manual of Indian Timbers* supplies much information on these points. The ambition of Sir Dietrich Brandis has been, he says, "to publish a pathfinder through the bewildering variety of trees, shrubs, climbers, Bamboos and Palms which constitute the forests in the different provinces

of India." The author, as we venture to think, very wisely, in a book of this character, takes a broad, comprehensive view of species. This is certainly more convenient for the practical forester who, with this guide before him, can divide and sub-divide on the spot according to the evidence and the conditions before him.

In a rather lengthy introduction, the author descants upon the climate and topography of the several provinces of India—an important summary, the value of which would have been enhanced by the use of side-headings or other devices to facilitate its consultation by the student. In the descriptive part of his volume, Sir Dietrich has, for the most part, followed the sequence of families adopted by Bentham and Hooker in their *Genera Plantarum*, with a few deviations, which will, we think, commend themselves to the botanical reader.

Comparatively few synonyms are given, but native names, such as the Indian forester is likely to hear, are freely quoted. The descriptions are brief but clear, and are followed by indications of the habitat and geographical distribution of each species. Occasionally anatomical details are given, which will be very serviceable, and will, it is to be hoped, lead forest officers largely to increase our knowledge in this direction. The three Cedars *Deodara*, *Libani*, and *Atlantica* are, for practical purposes, treated as distinct species, as are also the three Silver Firs *Abies Pindrow*, *Webbiana*, and *densa* of Griffith. *Cupressus lusitanica* (the Cedar of Goa) is found in a cultivated state in Western India, and is referred doubtfully to *C. torulosa* or to *C. sempervirens*.

The illustrations are helpful, and occupy in all some sixty pages. Considering the length of time required in dealing with such a mass of detail, the errata and misprints are very few, but numerous "addenda," which have accrued during the preparation of the book, have been added in a supplement. There is a copious list of vernacular names, and a detailed index to orders, genera and species. Bibliographical details and references to illustrations are somewhat scanty, but the necessity for compression is no doubt accountable for the omission of all except those which were absolutely necessary. The book is an example of energy, accuracy, and lucidity of treatment on the part of the author, who, by its publication, has conferred a benefit on Indian forestry which will be as lasting as it is valuable.

ICONES SELECTAE HORTI THENENSIS.—This publication, devoted to the illustration of plants growing in the garden of M. Van den Bossche, of Tirlmont, has now reached its sixth volume. The critical descriptions and notes are from the pen of M. de Wildeman, and are characterised by careful research and judicious comment, whilst the illustrations by M. d'Apresval are excellent. In the recent numbers are illustrations of *Rhus vernicifera*, tab. 201; *Echinocereus Salm-Dyckianus*, tab. 202, a species with cylindrical fluted stems and orange-coloured flowers; *Pisonia Brunonis*, tab. 203; *Agave deserti*, tab. 204, a species which flowers readily in cultivation. The spiny leaves of this plant greatly impeded the march of the soldiers in Lieut. Emory's Expedition in California in 1846; *Kniphofia Tysoni*, with reddish-yellow flowers, tab. 205; *Leucæna glauca*, tab. 206, a Brazilian Mimosa-like plant; *Tricholepis furcata*, a Thistle-like plant, tab. 207; *Teucrium fruticans*, tab. 208, a well-known old greenhouse plant, native of the Mediterranean region; *Grevillea asplenifolia*, tab. 209; *Lissochilus Krebsii*, tab. 210, a South African species extending to the Mozambique district, but treated as a cool greenhouse plant. In relation to this species, M. De Wildeman remarks that there is probably not a single species of plant of which we can certainly determine the limits of variation. How true this is is shown by the different opinions held by different botanists as to what constitutes a species and the consequent accumulation of synonyms.

THE ROSARY.

CULTURAL NOTES FOR APRIL.

STANDARD and dwarf Roses, despite the severe frosts of January and February, have, on the whole, a very healthy appearance. All manner of material used for protection, including the earthing around the stems, should now be removed, but the surface mulching should not be disturbed unless it be to renew it. All dead and decaying wood or any growths injured by frosts should be cut back to an outward bud on healthy wood. Standard and half-standard Briars with injured or decaying wood should also be cut down to firm, healthy growth, and afterwards sealed at their

generally, as it does its work quickly and answers for the general class of hardy trees and shrubs, but for Roses they are too crushing and bruising in their severing, and for that reason a cleaner cut with a sharp knife is better. Cuttings inserted in the open garden during last October should now have the soil about them well trodden, as they will probably have become loosened by the winter frosts. Renew and shake up the surface mulching about them, and if the weather is dry soak the ground well with water. An important matter during the early summer is the shading of the cuttings from strong sunshine, or there will be many losses. This can be done by sticking in the ground amongst the cuttings some leafy branches of evergreens that can be renewed when necessary.

the bud, except one, should be removed, together with any suckers that spring from the base of the stock. In the beds that were thinly planted during February with half-standard varieties room was left for planting, either now or early in May, Teas and Noisettes from pots, for the purpose of carpeting the ground with the long shoots that must be evenly and horizontally pegged down to 4 to 6 inches above the surface of the bed.

ROOTED CUTTINGS.

The most forward of the young plants on their own roots ready for removal from the hotbeds can now be re-potted into 4-inch pots and placed in a fresh hotbed that has been prepared in advance. The frames should be kept close for a

FIG. 98.—HELLEBORUS CORSICUS. COLOUR OF FLOWERS YELLOWISH-GREEN.

[Photo by E. J. Wallis.]

cut ends with a little grafting wax to prevent bleeding. Late spring-planted Roses and the more tender varieties of Teas should be sparingly pruned. Choice of proper stock is a great factor in successful Rose-growing. The climbing varieties of Teas and Noisettes with long growths succeed best when worked on the de la Grifferaie stock, and this especially applies to such varieties as Maréchal Niel, Mme. Berard, Aimée Vibert, Rêve d'Or, W. A. Richardson, Reine Marie Henriette, Cheshunt Hybrid, and Gloire de Dijon. The hybrid perpetual class flourish on either the Briar or the Manetti stocks, but they are stronger as dwarfs on the latter. Teas, Hybrid Teas, Hybrid Chinas, and some others succeed best on the Briar raised from cuttings or from seed. All these types of Roses and, in addition, standard Briars succeed best planted in a stiff loamy soil.

The secateur is a popular tool for pruning

RAISING STOCKS FROM SEEDS.

The seedling Briar is a good stock for the grafting of Tea, Hybrid Tea, and Noisette Roses, and the present is a suitable time to sow the seed. If the hips have been laid thickly together during the winter months they will now separate freely, and the seed will be found in a fit condition for sowing in shallow drills made a few inches in depth. Sometimes the seed will not all germinate in the first year. In the third year from the time of sowing most of the stocks will be of sufficient size to bud or graft upon, and in the third year it will be best to select those that are ready for working and to re-plant the smaller ones into nursery beds. By the end of the present month, or as soon as the sap becomes fairly active, the maiden budded shoots of standard and dwarf varieties should be cut back to within 2 inches of the bud, and after the latter has pushed a few inches, all the wild shoots above

few days, and be shaded when required, for the temperature should not exceed 65°, except with sun-heat. If the temperature exceeds this degree a little ventilation should be admitted at the back of the frame for a few hours daily. The plants when re-potted should be plunged 3 or 4 inches apart in the bed, and water should be sparingly given till the roots become active in the fresh soil. Pinch back the longer and more rambling growths to keep the plants compact and bushy. Ventilation can gradually be increased as the plants become established, and by the end of May or early in June the frames can be removed altogether. The new and old material of the hotbed should be incorporated and made quite firm to a depth of 3 feet. The plants can now be returned to the bed, plunged, and set far enough apart to allow for the season's growth. A good portion of them will probably require shifting again into 5-inch

or 5½-inch pots. The potting should be done without unduly disturbing the roots, and as a compost use yellow loam and decayed manure, with a dash of sharp river sand added to keep the mixture open. The last batch of the forced Roses should now be nicely in bloom, and the usual ventilating of the structure, watering, &c., will be all they require. The autumn and spring grafted Roses will now be making headway, and their potting should soon be brought to a close. All straggling growths should be stopped, and the plants be kept actively growing until the middle of May before placing them in the open air. Use the syringe mornings and evenings, and guard against attacks of aphids and mildew by the use of the vaporiser in the case of the former, and for the latter flowers of sulphur mixed with water and painted on the hot-water pipes. J. D. G.

FRAU KARL DRUSCHKI.

A RECENT number of *Le Jardin* contains a note by M. Cochet-Cochet concerning the origin of the name of this Rose from materials supplied by the raiser, M. Peter Lambert, of Trèves. In 1898 M. Lambert showed it at Stuttgart, unnamed. A schoolmaster who saw it at the exhibition said that it was a marvel and should be named "Schneekönigin," or Snow Queen. It was agreed that the name was good and suitable, so the Rose was thus spoken of at the time. In 1899, having increased the stock, it was shown again, still under its seedling number and without a name. In 1900, at an exhibition at Trèves, it was staged in competition for a prize of 1,000 marks offered on condition that the successful Rose should be named Otto von Bismarck. It did not gain the prize because the absence of colour was not approved. When the judging was over, and the jury saw the plant flowering in the nursery, they regretted their vote, but it was then too late. Naturally M. Lambert was vexed, and he then asked M. Druschki, the president of the society, if the Rose might take the name of his wife. The proposal was accepted, and that same evening the Rose received the appellation Frau Karl Druschki, by which it is now universally known.

THE WISLEY LABORATORY.

THE new laboratory buildings in the gardens of the Royal Horticultural Society, which we illustrate at fig. 100, are now completed. The buildings, which are of brick with a tiled roof, consist of three main rooms opening out of the entrance hall, together with one or two smaller ones. The front of the building faces west, and looks towards the range of glasshouses in the gardens. Entrance is gained through a glazed porch, which opens into an entrance hall. On the right of the entrance hall is the room designed for a research laboratory, where the laboratory investigations in connection with the experiments on various horticultural problems will be carried out. We understand that the subjects it is hoped to experiment upon in the near future include soil-sterilisation by steam as a means of destroying pests of plants which live in the soil; an investigation into the influence of sterilisation on the plants cultivated in the soil; study of the bacterial flora of the soil; etherisation of plants; and certain plant-diseases. Each of these subjects will entail a large amount of laboratory work, as well as experiments in the garden. Many other small problems are continually arising which will call for immediate investigation, and which can be settled in a short time in a well-equipped laboratory. Opening out of the research room at the back is a commodious and well-ventilated dark room for photographic purposes, while on the south side is a glasshouse for experimental work.

On the left of the entrance hall an office and storeroom are provided, while a loft, with a

boarded floor running over these rooms and the entrance hall, and reached by a trap-door in the ceiling of the latter, provides further accommodation for stores. The entrance to the main room or students' laboratory is in the hall, immediately opposite the main entrance. This is a large room, 36 feet long and 21 feet broad, where table accommodation for twenty-four students at one time will be afforded. The room is admirably lighted in all parts, so that microscopic work and dissections can be carried out under the most favourable conditions. Here the students in the gardens will be instructed

MR. F. J. CHITTENDEN.

in the scientific principles underlying the operations of horticulture, mainly by experimental and observational work carried out by themselves. The window frames are grooved so that light-tight blinds may be fitted, and the room thoroughly darkened at any time for lantern demonstrations. At the further end of the room a low platform is erected for the lecture and demonstration table, towards which the students' tables will face, and at the other end, on the right of the entrance, a fume chamber is built in which experiments with acids that give off fumes likely to be injurious to the instru-

Cupboards for books and apparatus are to be added, and round the wall, just below the windows, runs a range of lockers in which students will be able to keep their books and apparatus. Altogether, the building seems well fitted for the purposes for which it is intended.

The gentleman appointed to take charge of the laboratory is Mr. F. J. Chittenden, the Secretary of the Scientific Committee, whose experience as director of the laboratory at Chelmsford, and instructor in the theory of agriculture and horticulture will be of great service to him in his new appointment. His duties as a teacher will not be so engrossing as to prevent him from carrying on those scientific researches connected with horticulture, for which undertakings the laboratory is primarily intended. What precise direction his studies will take must, of course, be determined by circumstances. In the meantime, we may congratulate the society not only on the establishment of the laboratory, but also on having placed it under the direction of so competent a director.

HELLEBORUS CORSICUS.

THERE is a fine mass of this sturdy Hellebore in the rock-garden at Kew, where it receives partial shade from a Pine tree, and shelter from a belt of Rhododendrons. The photograph reproduced (at fig. 98) shows how happy the plant is in such a position. It has grown there for some years, and has flowered every February as freely as shown in the figure. The stems are 18 inches or more high, but either the weight of the leaves and flowers, or snow, has bent them over so that the stems are not shown. For the wild garden or shrub-border, this plant is just the sort of thing to grow in quantity. It is grown in some gardens as *H. lividus*; indeed, it used to be grown under that name at Kew, until the late Mr. Burbidge sent to Kew a plant of the true *H. lividus* brought by Miss Fanny Geoghegan from Majorca, where this species grows wild. This plant was figured in

FIG. 100.—VIEW OF THE LABORATORY IN THE WISLEY GARDENS.

ments in use, may be carried out. The rooms are heated by means of hot-water pipes and radiators, the water being supplied from the boilers, which heat the glass-houses. An abundant water supply is laid on in convenient places in the laboratories, and artificial lighting by means of acetylene gas, the generator for which is placed some distance from the main building, is provided. The gas will be laid on to every table for table lamps and heating purposes.

the *Botanical Magazine*, t. 7903 (1903), where Sir Joseph Hooker points out that although Lindley and others included *H. lividus* under *H. corsicus*, the species are quite distinct, horticulturally at any rate. The plant here figured has sharply-toothed, rather rigid leaflets and yellow-green flowers, whilst the leaves of the true *H. lividus* are obscurely toothed and softer in texture and the flowers are coloured a dull purplish grey. W. W.

The Week's Work.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower to Sir Trevor Lawrence, Bart., Burford, Surrey.

Dendrobiums.—In all large collections many plants, having been kept rather dry at the roots, and in a comparatively cool atmosphere since flowering, are making growths, and those plants that bloomed early have new shoots approaching to 1 foot in length. Such growths will soon produce roots from their base; the plants should therefore be examined without delay, in order that those which require larger pots, and others needing surfacing may be given suitable attention, after which they will require to be placed in their growing quarters. Later plants only now starting into growth may remain in the cooler house until the new shoots are sufficiently advanced to produce roots. Any old plants of special varieties that have deteriorated through loss of roots, or from overflowering, may be broken up, and those pseudo-bulbs that have not produced flowers should be cut off and laid upon some damp sphagnum-moss in the propagating case, or they may be cut up into short pieces and inserted as cuttings, in well-drained pots, using a mixture of sphagnum-moss and coarse sand. Young plants will soon appear from the nodes (leaf-axils), when they may be potted and grown on to take the place of the older examples next season. In re-potting the established plants, the roots should not be disturbed more than necessary. My practice is to carefully break the pot, and take away as much of it as is practicable, and, where possible, to pick out some of the old compost; then to place the whole into a pot of a larger size, placing crocks and bits of peat-rhizome up to the base of the compost, filling up and making the material moderately firm to just below the rim of the pot with equal parts of good fibrous peat and chopped sphagnum-moss, mixed together with sufficient small crocks and coarse sand to keep the materials porous.

Young seedlings that have started into growth may also be re-potted, and for these I use sphagnum-moss well mixed with small crocks and sand. For a few weeks following this operation, keep them rather on the dry side, but as soon as the young roots are seen pushing their way through the compost, afford water more frequently.

General treatment.—Nearly all *Dendrobiums* require a hot, moist atmosphere when growing, and an abundance of light, but they should be shielded from strong, direct sunshine until towards the completion of growth, when the plants will be greatly benefited by its influence. If an East Indian house is not available, the ordinary plant-stove will suit them admirably. As a guide to beginners, the following popular *Dendrobiums* may be mentioned: *D. nobile* and its allies, *D. Ainsworthii* × and its congeneric crosses, as *D. splendissimum grandiflorum*, &c., *D. Wiganianum*, *D. Wiganæ*, *D. Melpomene*, *D. Findlayanum*, *D. Clio*, *D. Dominianum*, *D. Burfordiense*, *D. Euterpe*, *D. Schneiderianum*, also all the *melanodiscus* and *chryso-discus* hybrids.

***D. Wardianum* and *D. crassinode*.**—Plants that were imported last January are also in need of fresh potting material, such as fibrous peat and sphagnum-moss to the depth of 1 or 2 inches. Fix the plants firmly in pots that may be suspended from the roof. The best position I have found for these difficult plants is in the Cattleya house, where they will be exposed to plenty of fresh air at all seasons.

PLANTS UNDER GLASS.

By J. G. WESTON, Gardener to H. J. KING, Esq., Eastwell Park, Kent.

The ventilation and shading of plant houses.—Having regard to the daily increasing power of the sun, the cultivator must be especially careful that both ventilation and shading are afforded as soon as necessary. A common mistake made by beginners in respect to ventilation is that they first allow the atmospheric temperature to rise far too high, and to remedy this, open the ventilators wide, thereby causing an inrush of cold air which, by decreasing the

heat in the house suddenly, causes the plants to suffer a check, which is generally followed by mildew and impaired health. If, from any cause, the house has been allowed to get too hot, the careful cultivator will open the ventilators to a safe degree only, and by lowering the blinds, damping the house thoroughly, and perhaps spraying the plants over, will soon reduce the atmospheric temperature without causing injury to the plants. The stove may now have an atmospheric temperature at night of 70°. On bright mornings it will soon rise to between 75° and 80°. At this stage admit a "chink" of air, if possible on the side of the house sheltered from cold winds. As the temperature continues to rise, let down the blinds, after which, when the glass stands at 85°, a little more air may be admitted, which will generally keep the house right until the afternoon, when it will need to be closed sufficiently early to allow the sun to raise the temperature of the house to a considerable degree. At shutting-up time, syringe the plants overhead, damping all stages, walls, and pathways. In hot weather this process may require to be repeated in the evening.

The intermediate house should have an atmospheric temperature at night of about 60°, according to the requirements of the plants at present occupying it. If some ventilation is not left open all night, it will be required early in the morning, probably on first entering the house.

The greenhouses which are filled with flowering plants should be kept as cool as possible, leaving some ventilators open all night and employing shade as soon as the sun shines directly on the house, because flowers under glass will soon fade if exposed to direct sunshine.

The Palm house.—A permanent shading will be preferable for the next six months in order to prevent the risk of the leaves becoming scalded or burned, as might happen from the slightest neglect in the use of blinds.

Winter-blooming plants.—Old plants of *Salvia splendens*, *Eupatoriums*, *Moschosma riparium*, *Coleus thyrsoides*, and similar plants, having been cut back and placed in a little warmth, have made shoots suitable for use as cuttings. All these plants make root readily if the young shoots are inserted in light, sandy soil and placed in a warm frame. After these are rooted, pot or box them up, keeping them growing steadily and pinching the tops of the shoots out as required to ensure a sturdy habit of growth.

THE HARDY FRUIT GARDEN.

By J. MAYNE, Gardener to the Hon. MARK ROLLE, Bickton, East Devon.

The watering of Wall Trees.—Some six weeks ago attention was called in this column to this important subject. At the present time there is at last a decided change in the weather, and it is hoped there will be a good fall of rain that will save the heavy labour of artificial watering. Should the fall be light, however, do not hesitate to add to it artificially while the surface is moist. March was drier here than in any year since 1899.

Grafting.—This operation is general, and the atmosphere being more moist now the bark will "run" easily. Examine trees that were grafted early, because the unusually hot weather experienced during the last fortnight in March may have caused the clay to crack. This must be syringed with clear water, smoothed over afresh with the hands, and a layer of moss tied over the clay, which may be moistened once a day in bright weather. Although most of the shoots that appear on the stocks of re-grafted trees require to be rubbed off, one here and there should be left to act as a sort of safety valve for the sap, which will accelerate the union of stock and scion.

Sweet Cherries.—These trees have an abundance of bloom, which will afford a shelter for aphids, and the Cherry is one of the first to suffer from their attack; a diligent search should be made every few days and the same remedy applied as advocated for aphids on Peach trees in last week's Calendar. One can quickly destroy the green fly; it is the black fly that is

capable of causing so much trouble and mischievous if allowed to get the upper hand. As soon as the fruits are visible and the nights become warmer, the trees may be syringed with Quassia Extract or with "Abol," a proprietary insecticide.

Plums.—It is many years since there was such a wealth of blossom on our wall trees, even the old Greengage variety presenting a picture of snowy whiteness, thanks to the insecticide syringed over the trees in February, which prevented the tits destroying the buds. The Plum tree is one of the worst offenders as regards pushing up sucker growths from the stock it is worked on. These should be destroyed early, tracing them to their origin and cutting them away with the knife. Whilst writing about "suckers," it may be cited that the Peach, Apricot, and Pear offend in this way, and require the same treatment.

A reminder.—Complete without delay all arrears in the matter of pruning and training of the Fig, late planted fruit trees, or bushes of any kind, as growth will be general even in northern districts by the time these notes are in print.

THE KITCHEN GARDEN.

By WILLIAM H. HONESS, Gardener to C. COMBE, Esq., Cobham Park, Surrey.

Tomatoes.—A batch of plants for planting against walls should be brought on a little in advance of those intended for the open ground, as these former may be planted out a fortnight at least earlier than the latter plants. Both batches should be kept in an atmosphere of intermediate temperature for a short time longer, but gradually hardening them and re-potting them as growth advances, until they are well established in pots measuring 6 inches in diameter. It should be so arranged that the plants will arrive at such a stage as just described by the end of the month of May or early in June, because it may reasonably be expected that the condition of the weather at that time will be favourable to the plants being removed to the open air. If the plants were ready for any appreciable length of time before it was possible to plant them out, they would get into a starved and excessively hardened condition, which would check growth for some time afterwards.

Carrots.—If small sowings of the early varieties were made in warm situations, as was previously advised, the seedlings will now be showing well through the soil. Make a further sowing of Early Gem or some similar variety in order to provide for a supply of roots at the time which will intervene between the earliest crops and the main crop. Seeds for the main crop may also be sown at the present time. In some districts Carrots are often a very difficult crop, and the sowing of seeds in April is attended with comparative failure, it being better in such cases to delay the sowing until about midsummer. The best remedy I can suggest for this state of affairs is that of deep digging and manuring, getting the preparation of the ground carried out earlier than such work is often done. The selection of varieties must be determined by consideration of the nature and depth of the soil. It would be useless attempting to grow good specimens of the Long Survey type in heavy, or shallow soil. In such conditions, varieties of the "intermediate" type should be chiefly depended upon for the supply.

Cabbages.—If this crop has been neglected, and the surface soil has not been frequently stirred with the hoe, there may be observed a tendency in the plants to run to seed, but where hoeings have been frequent and an application of nitrate of soda has been applied to the soil, the plants will now be making good progress. If the much needed rain would only descend, some early varieties such as Sutton's April would be fit for consumption by the time these lines are in print. This variety will be closely followed by Ellam's Early and Wheeler's Nonpareil, but although "Flower of Spring" is growing side by side with these, I cannot speak so highly of this variety, after a trial of three seasons, as some writers have done in the *Gardener's Chronicle*, excellent though it may be in some other districts.

FRUITS UNDER GLASS.

By ALEXANDER KIRK, Gardener to J. THOMSON PATON, Esq.,
Norwood, Alloa, Clackmannanshire.

The Muscat house.—The vines are now coming into flower, and will require a dry atmosphere and a night temperature of not lower than 70°, while the day temperature should not fall below 85°. Admit outside air by the top ventilators only, and close them early in the afternoon, when the thermometer registers 90° to 95°. Turn on the valves of the hot-water system at 6 p.m., and shut them again at 8 a.m. Open the ventilators in the morning, when the temperature of the house has risen 8° above the night minimum temperature, and gradually increase the amount of ventilation until midday, according to the aspect of the house; gradually diminishing it again from this time until 4 p.m., when the house should be quite shut, with a temperature of 90°. Go over the bunches at midday and dust them with a hare's tail or some other suitable brush, and at the same time give the rods a sharp rap with the hand to disperse the pollen. Tie the young growths to the wires and pinch out their points after they have developed three or four leaves beyond the bunch. Pinch the laterals at the first leaf, and rub out all other shoots as they appear.

Black Hamburg.—Vines in late houses are now showing their bunches; the night temperature should be increased to 65°, and that of the day to 80°. Give ventilation daily by the top openings if the weather is favourable, but close and damp the vinery early in the afternoon, using tepid water for the damping. At this stage do not hurry the vines which have little or no root action thus early. Turn on the valves at night time and shut them again in the morning if the weather is fine.

Early Tomato plants in pots are now showing their flowers. The temperature in which they are growing should not exceed 65° Fahr. at night time, and 75° to 80° by day. Admit outside air early in the morning, and keep the house drier than usual. Rub out all lateral growths as soon as they appear, and train the plants on a single stem, pinching them when they have reached the limits of their stakes or trellis on which they are trained. Give the trellis or stake a sharp tap at midday to distribute the pollen and thus assist the fruits to set. Afford tepid water to the roots as soon as the fruits commence to swell.

Tomatoes in 6-inch pots will now be ready for shifting into their fruiting pots (9-inch) or for planting into borders or boxes. The compost should consist of well-chopped, turfy loam with a liberal admixture of lime rubbish and wood ashes. To each barrow-load of the compost add a 6-inch potful of "vine and plant food." Before potting, see that the plants are not dry, and to any that require it give a good watering with tepid water. Pot and plant very firmly, and afford sufficient tepid water afterwards to settle the soil about the roots. After planting, stake and tie carefully—never tightly. Trim all on the single-rod system, rubbing out all lateral growths as they appear.

THE FLOWER GARDEN.

By A. C. BARTLETT, Gardener to Mrs. FORD, Pencarrow,
Cornwall.

Calceolarias.—If their flowering positions are ready for their reception, the bedding varieties may be planted out at the first suitable opportunity, for it is essential that these plants should become well rooted before hot, dry weather sets in. See that the plants are watered at the root before transplanting them, and after planting tread the beds evenly, finishing by hoeing the surface soil. It is assumed that the plants have been well hardened by leaving the frames open whenever possible—at night as well as by day. Such plants, even of the more tender species *C. amplexicaulis* are uninjured by slight frosts. Should more than 3° of frost occur we take the precaution of sprinkling the plants with cold water before the sun shines upon them. If the flowering quarters are occupied with spring-flowering plants, it will be well to transplant the *Calceolarias* into open pits, leaving ample room between each plant, and using a soil calculated to induce the formation of roots.

Violets.—As soon as the flowering is finished fresh plantings should be made. The single Violet will thrive in most soils, but the most suitable is a deeply-worked, fairly heavy, rich loam. Much fresh air is necessary for their well-being. When planting it should be remembered that the earliest flowers are obtained from a sunny bank, and the latest flowers are gathered from plants growing in cool positions, such as the north side of a hedge, where the shade is not too dense. Red spider being the Violet's greatest enemy, care should be taken to use only clean runners when planting fresh beds or borders. Of the many varieties, *Princess of Wales*, *Russian*, and *Wellsiana* yield the largest flowers, but many people prefer the perfume of the smaller-flowered *Czar*. The white variety *Comte de Brazza* is always acceptable.

Hardy aquatics.—Although hardy *Nymphaeas* may safely be disturbed at any time between the beginning of April and November, the best time for this to take place is just as growth commences, which is usually about the middle of April. Where the pond possesses a natural bottom, and there is a good annual deposit of humus, little need be done after the plants are properly sunk into position. In artificial ponds and Lily-basins, where there is no natural supply of food, it is necessary to give an annual top-dressing. Where it can be conveniently done, it is well to first drain off most of the water—choosing a dull day, for the leaves will quickly "scorch" when out of water. I have found the most expeditious method of applying the top-dressing is to place cakes of dried cow manure where they will best remain on the surface of the mound, or, if possible, pressing them into the soil, and afterwards lay on turves of loam with the grassy side downwards. A few sticks stuck through the turves will keep them in position.

PUBLIC PARKS AND GARDENS.

By W. W. PETTIGREW, Superintendent of the Parks and
Open Spaces in the City of Cardiff.

The provision of music in parks.—Many park-superintendents are not altogether enthusiastic in advocating the provision of music in public parks, as they are inclined to regard it somewhat in the same light as they do pyrotechnic displays and other forms of popular entertainment. When viewed strictly from the gardener's standpoint, there is little wonder at their taking up this attitude, as money spent on any form of amusement leaves nothing tangible behind to show for the expenditure, and there are few forms of entertainment upon which money can be so quickly and sometimes unprofitably spent, as music. One can hardly help sympathising with the superintendent, who may have had to curtail his expenditure on horticultural matters, standing by and seeing an expensive band playing on a wet day to only a few dozen visitors. If the sums of money expended annually in some towns for the provision of music in the parks were laid out on permanent work, such as the formation of lawns, plantations and flower borders, or the erection of conservatories, &c., a more lasting value would undoubtedly be obtained for the outlay.

A wider view.—It must, however, always be borne in mind that a parks department has to look beyond purely horticultural considerations, and has to do everything which is reasonable and within its power to make its parks and open spaces as interesting and attractive as possible to the greatest number of people. Music is one of the best means of attracting people to the parks, hence those in charge, instead of regarding it solely as an expensive luxury, should use it as a powerful means to an end. My own experience in this matter is that since the introduction of music into the parks here they have become exceedingly popular with every section of the community.

Methods of raising money.—The amount of money expended upon music and the methods of raising it vary considerably in different towns. In the larger cities sums varying from £1,000 to £10,000 are annually spent, while in the smaller ones it ranges from £25 to £500. By special Acts of Parliament several cities are permitted to charge the rates to the extent of ¼d. in the pound for the purposes of supplying

music; some towns are only allowed to spend such monies as may be derived from park property; many others have to depend upon voluntary subscriptions or on the free services of bands—a very unsatisfactory position for any town to be placed in.

A musical expert.—Where a large sum of money is annually expended upon music, it is always well to have a musical expert as adviser to the parks committee concerned, as the selection of bands and the class of music to be played are hardly matters upon which the ordinary parks-superintendent can be expected to give the best advice. Towards the end of May is usually considered early enough to commence evening band-performances in our parks. Prior to that date the evenings are usually so chilly that few visitors care to sit about to listen even to the best of bands playing in the open air. As this season is fast approaching, arrangements for engaging and allocating bands, if not already taken in hand, should be made without delay. When the amount of money available for the provision of music is definitely known, it is much the best plan to arrange the season's programme at the very beginning rather than engage and allocate bands as the season goes on.

Causes of extravagance.—Two matters which lead to the squandering of money on bands should be carefully guarded against by those who have to do with their selection and allocation. One is the favouring of local, inferior bands to the exclusion of better-class outside ones. The other is ward-jealousy. It is exceedingly bad policy to engage an inferior band, even at a lower fee than that paid to a good band, simply because its members are rate-payers, and it is equally bad policy to send a band to a small, open space in an out-of-the-way part of the town merely for the sake of satisfying the various wards and their representatives.

Provision of seats.—In parks situated in the better-class districts of towns, chairs should always be provided in the vicinity of bandstands, as by letting them during the performances at a penny each they become a source of considerable revenue. Last year in one of our parks a sum of £102 was secured by the letting of chairs. Printed programmes can also often be made a means of bringing in revenue, both by being sold to the public and as a medium by which tradesmen may advertise their wares.

Brass, reed and orchestral bands, and even male voice choirs have all, at one time or another, been employed here. The two last-mentioned proved the least satisfactory in the open air, yet they were appreciated as a change from ordinary band performances.

SUB-TROPICAL GARDENING.—Whilst agreeing in the main with *Puisne's* remarks respecting sub-tropical gardening in public parks (see p. 213), it appears to me he has omitted a very important point in connection with the subject of shelter. *Puisne* infers that it is unnecessary to introduce shelter on the S. and S.W. sides; but, in my opinion, shelter on these sides is quite as important as on any other. The sub-tropical garden at Battersea Park has earned for itself a world-wide reputation, and there it will be found that the S. and S.W. sides are protected, not only by the planting of tall-growing trees, but also by the raising of high mounds. In this we see the remarkable forethought of the man who planned this garden (J. Gibson), for the prevailing winds in the north temperate zone are the S. and S.W. anti-trades, therefore the importance of protection from such winds. *Puisne* realises the importance of protecting the tender foliage characteristic of most sub-tropical plants; he recommends protection from the cold N. and N.E. winds, but not from the winds that prevail, which, although perhaps not so cold, would prove equally disastrous by virtue of their force. It appears to me one should aim at selecting a site possessing these qualifications in the way of shelter where possible. Beds and borders should be at least 30 yards away from the tall-growing trees in the shelter belt for the benefit of those subjects that require full exposure to light and air. By careful and judicious planting, however, and a wise selection of plants, it will be possible to find suitable subjects for the shaded nooks as well as for the more fully exposed parts of the garden. S.T.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Special Notice to Correspondents.—The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.

Illustrations.—The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but he cannot be responsible for loss or injury.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY, APRIL 16—

Roy. Hort. Soc. Coms. meet.
British Gard. Assoc. Ex. Council Meet.
Shropshire Hort. Soc. Spring Fl. Sh. at Shrewsbury.

THURSDAY, APRIL 18—

Linnean Soc. meet.
Manchester & North of England Orchid Soc. meet.
Huntingdon Daffodil Show.

FRIDAY, APRIL 19—

Kent, Surrey & Sussex Daffodil and Spring Fl. Show at Tunbridge Wells.

SATURDAY, APRIL 20—

German Gard. Soc. meet.

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich—47° 6'.

ACTUAL TEMPERATURES:—

LONDON.—Wednesday, April 10 (6 P.M.): Max. 51°; Min. 41°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—Thursday, April 11 (10 A.M.): Bar., 29° 8'; Temp., 47°; Weather—Overcast.

PROVINCES.—Wednesday, April 10 (6 P.M.): Max. 49°, S.W. Ireland; Min. 42°, Scotland, N.

SALES FOR THE ENSUING WEEK.

WEDNESDAY—

Perennials, Border Plants, Hardy Bulbs, Azaleas, Palms, Ferns, &c., at 12; 4,000 Roses in variety at 1.30 and 8.30. at 67 and 68, Cheapside, E.C., by Protheroe & Morris.
Large quantities of imported and established Orchids in variety from various growers, at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.46.
Roses, Palms, and Decorative Plants, at Stevens' Rooms King Street, Covent Garden, W.C., at 12.30.

We have received the following communication relating to the interesting Service tree from Mr. Robert Woodward, Junior, Arley Castle, Worcester:—

"In the year 1678 Edmund Pitt, 'a very knowing botanist and alderman of Worcester,' wrote a letter to the Royal Society, from which an extract is printed in their *Philosophical Transactions* (vol. xii., 978), in which he says:—"Last year I found a rarity growing wild in a forest of this county of Worcester." He then gives the names of some early botanists and points out that they agree that this tree (*Pyrus Sorbus*) is commonly found in France, Germany, and Italy under various names, but that none of them

"Nor any of our countrymen as Gerard, Parkinson, Johnson, How, nor those learned authors Merret or Ray, have taken notice of its being a native of England. Nor," he continues, "have any of our English writers so much as mentioned it, saving that Mr. Lyte, in his translation of *Dodoneus*, describes it under the name of the Sorb-Apple, but saith no more of the place but that it groweth in Dutchland."

In describing the tree Pitt says:—

"It resembles the *Ornus* or Quicken tree, only the *Ornus* bears the flowers and fruit at the end, this on the sides of the branch." He continues: "Next the sun the fruit hath a dark red blush, and is about the bigness of a small Juneting Pear, in September so rough as to be ready to strangle one, but being then gathered and kept till October, they eat as well as any Medlar." Concluding, he asks: "Whether a verjuice made of this fruit, either ground with Crabs or Grapes, or, if plentiful, alone, would not, being kept for some time, prove one of the best acid-astringent sawces that Nature affords."

This is the first record of a *Pyrus Sorbus* having been observed as growing in Great Britain. He seems to have made a search in most of the botanical works of that date, and to have come to the conclusion that up till then no one had ever considered that this tree grew wild in this country.

The next mention of the *Pyrus Sorbus* is by Miller, who, in his dictionary, says, under *Sorbus sativa* (1731-1768) that

"The manured service was formerly said to be growing wild in England, but this, I believe, was a mistake, for several curious persons have strictly searched those places where it was mentioned to grow, and could not find it."

Perhaps they only searched the mountainous parts of Cornwall, where Ray, in his *Synopsis Methodica* (3rd Edit., p. 542) mentions it as growing, or the moorlands of Staffordshire, where Dr. Plott also mentions it as occurring (*vide infra*). Anyhow, we must take it that the "several curious persons" failed to search Wyre Forest with sufficient accuracy, for we still find authorities writing about this tree of Pitt's at a later date. In the *History of Worcestershire*, by Nash (vol. i., page 11), published in 1781, we find an account of this same tree. Nash gives the exact locality. He says:—

"In the eastern part of the parish" (Aka or Rock), "about a mile from Mopson's Cross, between that and Dowles Brook, in the middle of a thick wood belonging to Mr. Baldwin, is a very uncommon tree, which I suppose to be the *Sorbus sativa* pyramiformis mentioned by Pitt in the *Phil. Trans.* for the year 1678." In describing the tree he says: "The bark resembles the Pear tree, as does the fruit, except that it is not quite so large as the smallest Pear; the leaf and the blossom exactly resembles the Mountain Ash." He adds that: "The common people in the neighbourhood, among whom this tree has been esteemed a curiosity for upwards of a hundred years, call it not improperly the Quicken Pear tree."

The "common people," according to this historian, recognised that they had in their midst a tree of some interest, but from the fact that they recognised it as "a curiosity" for only upwards of a hundred years points rather to the conclusion that their knowledge only sprang from the notoriety which probably had been given to it by that "knowing botanist" Pitt in 1678. We also learn from Nash that the gardeners of Sir Walter Blount and Sir Edward Winnington both tried to graft and bud it, and also to plant cuttings, and that he himself intended to try and raise some plants from seed if the fruit ripened. Search fails, however, altogether to prove that the gardeners of the above-named baronets were successful in their laudable endeavours to raise descendants of this unique tree. Nash informs us that at that date (1781) he knows of no other specimen in the county.

Nash gives a fine plate of this historic tree, and its height is stated as 40 feet. The next writer who mentions the tree is Smith, in his *English Flora* (1824-1828). He says that there is no positive habitat given, except that of a solitary tree in Wyre Forest, near Bewdley, Worcestershire.

Again, in the *Arboretum et Fruticetum Britannicum* (1854, 2nd edit.), we find Loudon saying (vol. i., page 23) that "The Mulberry, the Chestnut, and Fig, and the *Sorbus* or true service were introduced by the Romans." He adds:—

"It is singular that not far from one of the very few habitats in which the true service is to be found in a wild state in Britain, viz., Wyre Forest, in Worcestershire, the remains of a Roman villa were some years ago discovered (see *Arch. Mag.*, ii., p. 94),"

and he thinks that it is not improbable that the tree referred to may be a descendant from a service planted in the orchard belonging to the adjoining Roman villa. He gives a drawing of this tree, which was sent him by the Earl of Mountnorris, and says that the tree is "of great age, and is now in a state of decay." He states that in France the tree lives to a great age, and that some specimens are believed to be 1,000 years old. The height of the tree is given as 45 feet and diameter of the trunk 1 foot from the ground 1 foot 9 inches. He says that the tree is tender when young, even in France, and that the grafting operations require to be performed with the greatest care because it is the most difficult of all non-resinous trees to graft successfully. Small wonder, then, that the efforts of the two gardeners mentioned above should have been crowned with such little success.

But to return to Pitt's historic tree now nearing the end of its life. In *The Botany of Worcestershire*, by Edwin Lees (1867), at page 4, we read that in July, 1853, the tree was

"In a very decrepit state, with lank, bare and lofty branches, and only exhibited vitality at its very summit. Very little fruit was then produced, and the Sorb tree presented a scraggy and decrepit aspect. This venerated sylvan monument which, left only to Nature's care, might have existed for centuries longer, was mischievously burned down in 1862."

In a footnote we read that Dr. Plot, when he mentions that the Sorb tree grows "in the moorlands of Staffordshire," may have been referring to this tree, for a portion of Staffordshire, viz., Upper Arley, approaches very near to the Wyre Forest.

Lees' theory as to the existence of the Sorb tree in Wyre Forest differs from Loudon's; he is of the opinion

"That the tree was brought over from Aquitaine and planted beside a hermitage in the forest by some recluse, who was visited by those who venerated the tree for its protective powers." He says: "I was assured by an inhabitant of the vicinity that the hard fruit of the Sorb was formerly hung up in cottages as a protection from 'the witch,' and even now the idea of its virtues has not quite died away. Its relationship to the Mountain Ash, still superstitiously regarded in Scotland, renders it likely that this tree should be considered equally, if not more powerful, as a charm against witchery. A mound of stones now overgrown with brambles may be noticed by close inspection near the tree, probably the remains of the hermitage, for many existed previous to the Reformation in the north of Worcestershire. The hermit perhaps had a garden, for the Privet and the *Prunus*

domestica grow close by, though I did not see them elsewhere in the forest."

In Lees' book we find "our very knowing botanist" referred to as "Mr. Edmund Pitts, an Alderman (and probably a medical practitioner)." He also tells us that the Sorb was considered an old tree by Pitt in 1678. He relates finally that

"Mr. George Jordan, an untired explorer of

It is comforting to be able to relate that the ruffian met with a reward he justly deserved. When visiting the spot some few years ago, in company with an old woodman of the forest, we were told that the destroyer was caught, and convicted of setting fire to some farm buildings, and transported. Lees obtained pieces of the wood that survived the fire, and they were carved into drinking cups,

are now flourishing specimens in the Arboretum at Arley Castle, Worcestershire.* They were planted probably between 1800 and 1820; the best specimen measures 55 feet in height and 7 feet 4 inches in girth. A plate of this tree is given in vol. i. of *The Trees of Great Britain and Ireland*, by Mr. Elwes and Dr. Henry. It is still called locally the Whitty Pear tree. Many methods have

FIG. 101.—*AGAPETES SPECIOSA*, NEW SPECIES, FLOWERS CRIMSON. SINGLE FLOWER, AND SECTION SHOWING LONG-TAILED ANTHERS. (See "New or Noteworthy Plants," p. 230).

Wyre Forest, regarded the Sorb tree with almost filial love, and that its wanton destruction by ruffian hands was a source of much grief to him, and that he gathered up with decent care the relics that were left of the limbs of the old veteran, some of which he yet retains."

Thus ends the history of Pitt's famous tree, first mentioned by him in 1678, and then considered an old tree, and burnt down by a vagrant in 1862.

and are in the possession of a member of his family at the present time. Other relics are also extant among people who reside in the locality.

It remains to add that the Earl of Mount-norris, whom we have mentioned above as writing to Loudon on the subject of this tree, succeeded in raising two seedlings from it before it was burnt down. These two trees

been tried of propagating this tree, and the writer is informed that success has only been obtained by sowing the pips, which have been obtained from the Pears when they have become rotten. As Loudon points out, the seedlings have been found to be very delicate

* Arley Castle is in the parish of Upper Arley mentioned by Lees above as approaching very near to Wyre forest, and being then in the County of Stafford. The parish has recently been transferred into the County of Worcester.

in the early stages of growth; they are kept in a cool house for the first four or five years during the winter. During this time they only grow about 12 inches, but afterwards they make rather rapid growth up till about the fifteenth or twentieth year.

One seedling raised in this way is growing in the garden of The Precentory, Worcester, and is now 13 feet high and 13 inches in girth. It is about 20 years old, and has not yet borne any fruit.

There are other younger specimens growing in the Arboretum at Arley Castle, by which the interest in Pitt's historic tree may still be maintained.

The fruit, if kept till October, eats like a Medlar, as Pitt observes above. Virgil tells us that the juice of the Sorb was used when wine was unprocurable.

..... *et pocula laeti,
Fermento atque acidis imitantur vite sorbis.
—Georg. III. 380.

But we doubt whether the liquor so obtained would be very acceptable to anyone at the present day." [There are two good specimens of this tree in the Oxford Botanic Garden.]

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the Committees will be held on Tuesday, April 16, at 8 p.m. A lecture on "Rainfall in its Relation to Horticulture" will be delivered by Mr. R. H. CURTIS.

THE BOTANICAL MAGAZINE. This venerable publication, for so many years edited by successive directors of the Royal Gardens, Kew, opens its April number with a figure of:—

DIOSPYROS KAKI (Linn.), tab. 8,127.—Flowers and fruit are produced annually in the succulent house at Kew. Mr. HEMSLEY contributes a brief account of the history of the tree, in the course of which he mentions it as fruiting in the garden of Sir WILLIAM HUTT, in the Isle of Wight. He might have added, unless we are mistaken, that it has fruited against a wall in Canon ELLACOMBE's garden at Bitton.

ARCTOSTAPHYLOS MANZANITA (Parry), tab. 8,128.—A Californian shrub hardy at Kew with stalked ovate, oblong leaves like those of Gaultheria Shannon, and terminal nodding clusters of pink urceolate flowers.

CALLIANDRA PORTORICENSIS (Benth.), var. major (Strague), tab. 8,129.—A shrub with delicate, Mimosa-like foliage and stalked heads of whitish flowers, the numerous long stamens forming balls of threads.

MECONOPSIS BELLA (Prain), tab. 8,130.—An East Himalayan dwarf species flowered first in the Botanic Garden, Edinburgh. The foliage is much divided and the flowers are borne singly on long, erect stalks. The petals are of a violet colour and contrast with the golden stamens.

CYMBIDIUM ERYTHROSTYLUM (Rolfe), in *Gardeners' Chronicle*, 1906, vol. XL., p. 286, fig. 115, and in *Botanical Magazine*, tab. 8,131.—The flower segments are white but the lobes of the lip are marked with reddish stripes and the column is reddish violet. Introduced from Annam by MICHOLOITZ when collecting for Messrs. SANDER & SONS. It flowered first at Glasnevin.

LYONS HORTICULTURAL EXHIBITION.—A horticultural exhibition will be held in Lyons from May 16 to 20, in connection with the Sociétés Lyonnaises d'horticulture, and on the occasion of the National Agricultural Conference and the visit of the English and Scottish Municipalities. Details can be obtained from M. PHILIPPE RIVOIRE, Secretary, Lyons.

*"And for cups of wine make shift with beer and the cider of sour service-berries."

HORTICULTURAL CLUB.—The next House Dinner of the club will take place on Tuesday, April 16, when Professor BOTTOMLEY will talk about "Soil Inoculation."

THE DRESDEN EXHIBITION.—Prof. DRUDE is organising a department of the exhibition to illustrate the history of horticulture. The first period ranging, from A.D. 800-1500, comprises indigenous plants, or those from the south of Europe. 2, the Tulip period, 1560-1670, coincides roughly with the introduction of the Potato, Maize, Horse Chestnut, &c.; 3, the South African and N. American period, 1679-1770, characterised by the introduction of Aloes, Mesembryanthemum, Pelargonium from the Cape, the Weymouth Pine, Hemlock Spruce, Tulip, and other trees from N. America; 4, the period of the introduction of New Holland plants, Acacias, Banksias, Epacris, Araucaria, &c.; 5, the existing epoch, 1830-1900, marked by the utilisation of plants from Eastern Asia, N.W. America, Palms, the extensive introduction of Orchids, &c. The second department of the exhibition is devoted to the display of original works on horticultural botany, relating especially to Germany. A third section is to comprise architectural styles, landscape gardening, &c. Other divisions will include illustrations of vegetable biology, research-stations, schools of horticulture, hybridisation, diseases of plants, and horticultural literature.

KINGSTON VICTORIA HOSPITAL.—A flower show and fete, in aid of the funds of this institution, will be held in the grounds of Elmfield, London Road, Kingston, on Wednesday, July 3rd, 1907. Mr. ALEX. DEAN, 62 Richmond Road, Kingston, is superintending the floral portion of the exhibition.

DAFFODIL SHOW AT BIRMINGHAM.—In respect to the show of the Midland Daffodil Society, to be held in the Edgbaston Botanic Gardens, on the 28rd inst., Mr. Robert SYDENHAM writes us to the effect that there are expectations that this exhibition will be one of the best Daffodil shows of the season, and one of the best "that has ever been held in the world."

A REMARKABLE SALE CATALOGUE.—The catalogue of duplicate orchids from the collection of FRANCIS WELLESLEY, Esq., Westfield, Woking, to be offered, without reserve, by Messrs. PROTHEOR & MORRIS, at their Central Auction Rooms, on April 23 and 24, is the most remarkable publication of its kind we remember to have seen. It extends over 76 pages, and is illustrated by 40 artistically-produced illustrations of some of the leading kinds. The catalogue contains a very extensive set of white-petalled and albino Cattleyas; the extraordinary Brasso-Cattleya Mrs. Francis Wellesley, and a rich selection of Cypripediums, including the fine C. Thalia Mrs. Francis Wellesley, which at the sale of duplicates last year reached the record highest price for a Cypripedium ever obtained at auction.

MR. JOHN BURN, late Superintendent of the Parks and Gardens of the Leicester Corporation, is engaged in laying out and planting the grounds of the new Leicestershire Asylum at Narborough. Considerable progress has been made with the work. A belt of trees and shrubs extending about two miles round the estate has already been planted, and a wide walk cut out alongside, which does credit to the designer and planter.

THE CLASSIFICATION OF PEACHES.—In a recent issue of *Gartenflora* Herr R. GOETHE, of Darmstadt, prints a paper upon the classification of Peaches. His system is based upon comparison of the size of the flowers; the size, shape and corrugations of the stones, and the glands of the leaves. The article is fully illustrated.

THE AMERICAN GOOSEBERRY-MILDEW IN IRELAND.—Dr. PETHYBRIDGE has a paper in the April number of *Irish Gardening*, in which he says there are at present about 100 gardens in Ireland in which the disease has manifested itself. An illustrative map shows that the greatest number of cases are in the N.E. of Ireland, that the South and N.W. are at present nearly exempt; elsewhere the disease is scattered. It was first noticed in Antrim in 1900. The losses have already been most serious, but the disease has been completely eradicated from some localities, and spur-pruning and spraying with potassium sulphide have had the desired results. Spraying, says the writer, must be thorough, and it must sooner or later come to be regarded as part and parcel of the normal operations of fruit-growing. In the case of the Gooseberry, the spraying must be begun at once, and frequently repeated. It should be needless to repeat that bushes seen to be affected with the mildew should be burnt forthwith.

Professor SALMON is indefatigable in his endeavours to awaken Gooseberry growers to the danger that may accrue from the spread of this mildew. The destruction by fire of affected bushes, and the necessity for spraying with sulphide of potassium ($\frac{1}{4}$ oz. to a gallon of water) are both alluded to. Mr. SALMON quotes a letter from Prof. BEACH, to show that where treatment is begun early, and repeated at intervals of from seven to ten days, the disease may in some seasons be controlled, but that spraying is not so efficacious as eradication. Hence the advice to destroy affected bushes by fire as soon as the disease is detected, and thus check its spread.

—During the past week, commencing April 1, I have experimented with fresh potassium sulphide on some of my Gooseberry trees, and I repeated the application yesterday, April 6. The solutions used were respectively $\frac{1}{4}$ oz., $\frac{1}{2}$ oz., and 1 oz. to 1 gallon of water. We have no mildew; the experiment was to test the effect upon the young leaves. No injury has been caused by either of the solutions. The bushes (one long row) are growing under a row of standard Plums and standard Pears. J. Udale.

THE NURSERYMEN, MARKET GARDENERS, AND GENERAL HAILSTORM INSURANCE, CORPORATION, LIMITED.—We are informed that the 12th annual general meeting of the shareholders of this corporation was held at 41 and 42, King Street, Covent Garden, on Friday, the 5th inst., presided over by the chairman, Mr. Harry J. Veitch. The business showed an increase in both premiums and interest on investments over previous years. The area now insured is 35,088,527 square feet of glass, valued at £479,531 16s. 8d. A dividend at the rate of 7½ per cent. was declared, together with a bonus of 2½ per cent.; £1,500 was placed to the reserve fund, making a total of £12,000. Five claims were paid during the year.

THE DAHLIA NEWS.—We have two Dahlia societies in this country, but our American friends have surpassed us by the issue of a monthly bulletin. The first number comprises only four pages, two of which are occupied with official details, but the editor deprecates severe criticism, and so long as he "does his best in a sincere and honest way," he has nothing to fear, even though he be "no journalist." The New England Dahlia Society was organised November 2, 1906, for the purpose of promoting the culture and development of the Dahlia; to accurately determine the several classes thereof; to disseminate information and to secure uniformity in awarding prizes at the various flower shows; to establish a standard nomenclature, and to award recognition to new varieties of sterling merit. All communications should be addressed to Mr. MAURICE FULD, 5, Union Street, Boston, Mass.

THE NATIONAL CHRYSANTHEMUM SOCIETY'S YEAR BOOK.—The Chrysanthemum Society, following the lead given it for so many years by the Rose Society, has published its first Year Book, and we feel sure that country members, indeed all the members, will give it a good welcome. The frontispiece is a capital portrait of the popular President, Mr. C. E. SHEA, concerning whose horticultural career some interesting details are given. The editors are Messrs. C. H. CURTIS and C. H. PAYNE, and the following subjects are briefly treated upon by the several contributors: Chrysanthemums in America (C. H. TOTTY), Chrysanthemums in Decoration (DOROTHY M. OLIVER), Early Chrysanthemums from Stool Divisions (PERCY A. CRAGG), Chrysanthemums in Australia (T. W. POCKETT), Exhibition Incurved Chrysanthemums (W. HIGGS), Analysis of the National Chrysanthemum Society's November Shows, 1905-6 (C. M. COLLINGWOOD), Chrysanthemums for Town Gardens (ELDERBERT F. HAWES), Work of the Floral and Classification Committees for 1906 (D. B. CRANE), Market Chrysanthemums (DAVID INGAMMELLS), Single-flowered Chrysanthemums (W. C. PAGRAM), New Chrysanthemums of 1906 (CHAS. H. CURTIS), and New French Incurved Chrysanthemums (C. HARMAN PAYNE). Writers and editors alike are all photographed, and readers may therefore obtain some knowledge of the personality of the teachers, whilst carrying out their precepts. The printing is clear, and the paper good, whilst a thick cover in a pretty shade of green gives to the book quite an attractive appearance. The price is one shilling to non-members of the society, and the publishers are Messrs. SIMPKIN, MARSHALL, HAMILTON (not MAMILTON, as printed on title page), KENT & Co., LTD.

BEAUTIFUL GARDENS.—In *Beautiful Gardens*, issued by Cassell & Co., Ltd., Mr. WALTER P. WRIGHT, horticultural superintendent under the Kent County Council, explains how to make flower gardens of rare beauty, how to make them quickly, and how to make them cheaply. The work is enriched with a series of practical plans and diagrams, in addition to a large number of garden photographic pictures. The book contains two coloured and 48 half-tone plates.

SOME HANDSOME PETUNIAS.—Herr ERNST BENARY, of Erfurt, forwards a large coloured plate of Petunias with the needlessly cumbersome name of "*Petunia hybrida grandiflora fimbriata*"; that is to say, handsome hybrid Petunias of various colours with fringed petals that he has succeeded in raising. These, in size and colouring, are worthy of the reputation of this well-known firm.

GARDENING IN MADRAS.—Sir JAMES THOMSON, in a lecture before the Society of Arts, says:—"Gardening is a favourite occupation with many; every house has its surroundings of Croton and other foliage plants and shrubs. Rosaries and ferneries are common. Some are able to put down attractive lawns; and in the cool weather with care and attention flowers are in profusion. The water supply and the easy procurements of seeds and plants have, of course, made all this a much easier matter than it once was."

CAPE FRUIT.—The *Cape Times* of the 13th ult. contains a series of interesting illustrations which serve to give some idea of the extent and importance of fruit-culture in that part of South Africa. The figures include representations of a Peach orchard, various illustrations showing the growth, picking, and marketing of Grapes, Peaches, and Figs, the arrangements for cold-storage, and for transshipment.

ROYAL METEOROLOGICAL SOCIETY.—An ordinary meeting will be held at the Institution of Civil Engineers, Great George Street, Westminster, S.W., on Wednesday, April 17th, 1907, at 7.30 p.m. Papers will be read on the following subjects: 1.—"Phenomenal Rainfall in Suva, Fiji, August 8th, 1906," by ROBERT L. HOLMES. 2.—"Temperature around the British Islands in relation to the Gulf Stream," by RICHARD STRACHAN. 3.—"Weather regarded as a Function of Climate," by L. C. W. BONACINA.

JOHANNESBURG PARKS.—From the report of the superintendent, it is evident that great progress is being made in the development of parks and open spaces, and in the lining of the streets with trees. No fewer than ten parks, one comprising a zoological collection, must give no small amount of labour to the superintendent, Mr. A. H. STIRRETT, who holds a certificate from the R.H.S. We are glad to see that it is intended to cultivate representatives of the Transvaal Flora, and not to copy European models too slavishly.

TRANSVAAL TREES.—In the *Transvaal Agricultural Journal* for January is a valuable paper on the native trees of the Transvaal by Mr. J. BURTT DAVY. Attention is called to the different climatic zones of the Transvaal and to the trees which are peculiar to each. In all, 209 species are enumerated. This list is drawn up preparatory to a more complete account of the trees and their uses, upon which Mr. BURTT DAVY is engaged.

THE ACTION OF FROST ON FRUIT TREES, &c.

—The Birmingham Department of Economic Zoology would be grateful for answers to any of the following questions. In each case, the informant is desired to give only facts, for the accuracy of which he or she personally can vouch. When filled in, these papers should be returned to WALTER E. COLLINGS, the University Department of Economic Zoology, 55, Newhall Street, Birmingham. 1, At what time of the year do frosts do most damage? 2, What crops suffer most? What parts of the plants are damaged? 3, In the case of trees, are different parts of the tree liable to be affected differently? (e.g., upper or lower branches, branches on different sides?) 4, In the case of sloping ground, what aspects have you found most free from injury from frost, and what aspect most liable to damage? 5, Is a garden in which frosts occur most frequently necessarily one in which the frosts do most damage? 6, In your opinion, is the damage done by the actual freezing, or during thawing? Do you think that if the thawing took place very gradually the damage would be much less? 7, Which of the following situations have you found to be best, and which worst:—(a) the bottom of a valley, (b) the side of a hill, (c) the top of a hill? 8, Do plants which are under trees suffer to the same extent as those planted in the open? 9, In your opinion is the presence of moisture in the atmosphere beneficial or otherwise? 10, Are frosts more injurious in the neighbourhood of water, e.g., river, brook, or pool? In such cases does the size of the piece of water make any difference? 11, Have you had experience of land near a river? If so, have you found any differences between the two sides of the river as regards injury by frost? If you have observed any differences, state the direction in which the river flows and the direction of the winds which are associated with frosts. Have you had any experience of the occurrence of frosts on small islands in river or pool? 12, Have you noticed any difference between different sides of any large sheet of water? 13, Do injurious frosts occur on still or windy nights, or both? 14, State the positions of any districts which are notoriously free from

injury by frosts, and of others which are notoriously liable to damage. 15, Are frosts which occur after rain any worse than those which occur in dry weather? 16, What preventive measures have you found useful? 17, In your opinion are there any varieties of fruit trees, &c., which are more resistant to frosts than others? 18, Have you observed any difference in the liability to injury of crops, &c., on different soils? If so, which soils have you found best, and which worst? Any information other than that required by the above questions will be useful if it is the result of personal observation. Notes made at the time as to direction of wind, state of the atmosphere, and position of injured gardens would be of great value, especially if such notes were made regularly by a large number of trained fruit-growers and gardeners in different localities. Information with regard to any differences between lands lying on different sides of a town or village would also be very acceptable.

Publications Received.—*Weston-super-Mare Chrysanthemum Society*. Prospectus of exhibition, to be held November 14.—*Oesterreichische Garten Zeitung*. March.—*Annalen des K. K. Naturhistorischen Hofmuseums*. Band XX., No. 4.—*Bullettino della R. Società Toscana di Orticoltura*. Vol. XII., 3rd Series.—*The Place of Rural Economy in a University Curriculum*. An inaugural address delivered at the schools by Prof. William Somerville, Oxford.—*Proceedings of the Agri-Horticultural Society of Madras*. July to September, 1906. The secretary, Mr. L. E. Kirwan, reports the loss of *Lodoicea Seychellarum*, a Palm unique in having grown from the first seed that successfully germinated in Madras. Excessive moisture at the roots was the cause of its death.—*Report of the Work of the West Virginia Experiment Station*, for the years 1905 and 1906. Mr. J. H. Stewart, the director, tells of useful research and work, chiefly in connection with the San Jose Scale and other injurious insects and growths.—*Louisiana Agricultural Experiment Station*. Summary of results with vegetables and fruits at the station from 1892 to 1907. By E. J. Watson. Much of the work was of a "pioneer" description on new ground but has been continued uninterruptedly and with results useful for future growers.—*The Museum Gazette*. March, Contents: Hollow Yew trees, Oak tree trunks and their vestments, Moss and Hepatics, by Rev. E. N. Bloomfield, and seasonal notes.—*How Landlords can create Small Holdings*. Some examples, by L. Jebb; and *The Working of the Small Holdings Act*, with suggestions for its amendment, by L. Jebb.—*Bananas and All About Them*, by J. H. Cook. A plea for the still more extended use of Bananas, and a useful set of recipes for cooking and serving these fruits.—*The Report of the Royal Society of St. George*. This society is still working away to instil patriotism into all classes of Britons. The Prince of Wales is now the president of the society.—*Report on Botanic Gardens in New South Wales for 1906*. Mr. J. H. Maiden announces successful alterations in the Sydney Gardens and good progress in other departments, hindered mostly by Nut grass (*Cyperus rotundus*), which was eventually overcome.—*Annual Report of the Forest Department of Madras*. To June 30, 1906. About 180 square miles of forest were added to the Presidency in the year. Experiments were made with exotic and other plants, and "where all officers have worked hard and willingly it would be invidious to mention any particular one." Mr. Brasier's report is considered to be highly satisfactory.—*Revision of the Genus Spilanthes*, by A. H. Moore, from the Gray Herbarium, Harvard University.—*Flax Culture*, by H. L. Bolley and W. L. Marcey, U.S. Department of Agriculture.—*Some Facts concerning Fertilisers and Their Use*, by Prof. Harcourt, Ontario Department of Agriculture.—*Insecticides and Fungicides*, by Prof. Harcourt and Mr. J. L. Fulmer, Ontario Department of Agriculture. A very useful summary of information on this subject.—*Results of Acclimatisation Work at the Saharanpur Botanical Gardens*. Compiled by the late Mr. W. Gollan, superintendent, with preface by Mr. W. Moreland, director. For years past the Saharanpur Gardens have been used as a testing station for exotic plants of economic value. The results with the principal species under observation are here detailed, and testify to the value of the work.—From the U.S. Department of Agriculture, Bureau of Plant Industry: *Tobacco Breeding*, by A. D. Shamel and W. W. Cobey; and *Seeds and Plants Imported*, during 1904-5.

NEW NARCISSI.

THE varieties Homespun and Open Face, shown in the illustrations at figs. 102 and 103, were shown by Mr. Dawson, Penzance, at a meeting of the Royal Horticultural Society, on April 2. Homespun (Engleheart), which was recommended a First-Class Certificate, is a short-crowned, yellow flower of very symmetrical form (see report of Truro Show, p. 242). Open Face has also exquisite form, a white perianth, and a remarkably flattened corona.

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

MISTLETO ON LIME TREES (see p. 224).—Sixty years ago (April, 1847) when commencing my gardening career, I was struck with the contorted branches in elongated form, and the twigs having a "witch's besom"-like appearance, in the case of some Lime trees bounding the grounds of Stillingfleet Vicarage, East Riding of Yorkshire. Though Mistleto (*Viscum album*) was sparingly present on the normal branches, there was nothing to account for the contortions although there were some excrescences, and where, evidently, some outgrowths had died or been broken off. This appears to confirm Mr. Elwes' suggestion that the contortions were due to the diversion of the sap at the particular points where manifestly there had been Mistleto which had been culled by the village youngsters in previous years. The vicar in residence in 1835 was renowned for his tolerance and sympathies with the villagers, not the least of his activities being the promotion of allotments and small holdings. Not a cottage was without one or both, in addition to a large garden attached to the dwelling at the time of the repeal of the Corn Laws and the advent of the Potato murrain. But to revert to the swellings on Lime trees, I may say that similar growths occurred on branches of Hawthorn (*Crataegus oxyacantha*), on Poplar (*Populus tremula*), and Crabs (*Pyrus Malus*), Mistleto being present on these trees, and no doubt the swellings were due to the growth being arrested where Mistleto had taken root and been removed at some prior period. Strangely, no Mistleto existed on Apple trees in orchards in the locality. Lime trees, as is well known, produce large swellings in the branches at the points where headed or pollarded, and this increases as the process is repeated, so that the growths become club-like, and have a very unnatural appearance, as may be seen in the case of trees on the north side of the burial ground attached to St. Alban's Abbey, near the ancient gateway of the once flourishing monastery and the present grammar school now being enlarged. G. Abbey.

Mistleto is remarkably plentiful on Lime trees in the grounds at Hampton Court Palace, and the swellings or protuberances mentioned by Mr. Elwes, p. 224, are abundant. Probably one of the worst examples I ever saw of these elongated swellings or elbows on the Lime induced by Mistleto was at Dropmore, where one tree, standing almost alone in the park, used to present an effective example of the evil of allowing this parasite to disfigure and injure what would otherwise have been a fine specimen tree. I think any person seeing that tree, if still standing—and Mr. Page will perhaps say if it is—would never permit Mistleto to grow on trees under their control. I have often marvelled that this parasite is permitted to infest and disfigure the Lime trees at Hampton Court, but possibly were the bunches of it so abundant there removed, some alarmist, through the daily papers, would raise a loud cry of spoliation. A. D.

Mistleto is present on several Lime trees here, and in almost every instance the branches have become malformed. One tree has upwards of 50 of these gourd-like outgrowths, and the appearance is very grotesque. Some of the bunches of Mistleto are more than 3 feet or 4 feet through. The parasite is also present on Poplar, Oak, Elm, *Crataegus*, and Apples, and it was also growing on a Horse Chestnut. We have another curiosity—a Holly and Ash having grown in close proximity at the base and again 10 feet from the ground; both trees appear very healthy. D.W.

HARDY PRIMROSES.—Quite an industry has sprung up during the last few years in the cultivation of this modest flower for market purposes. The florist has turned his attention to raising new varieties, some of which are charming; one of these, named Evelyn Arkwright, is fine of form, sweetly scented, and the flowers are extra large. The Wilson seedlings are elegant and most pleasing in colour, ranging from bright lavender-blue to deep violet-blue. The double Primroses are all free bloomers, and are useful for planting in the border or in the rock garden. They may be had in white, lilac, purple, sulphur, and crimson-coloured varieties. After flowering they should be lifted and divided, and planted in rich deep soil in a partially shaded situation. Mulch and water them during dry weather, and transplant them to their permanent beds in autumn. T. W. Birkinshaw.

ing would thus be presented! If it be said that the cost of so preparing the produce would be too great, certainly the public, being thus able to purchase greens by weight, every portion of which was edible, would gladly pay double the price now paid. Still, farther, what a big weight of garbage would be saved carting to market. Whilst there has been abundant criticism of our insular fruit marketing methods, and it is, unfortunately, owing to our stolid indifference, still necessary, as we seem not to have improved one degree in marketing our vegetables. I can see no advance on what I was familiar with 60 years ago. Whilst our growers complain of the effect of foreign competition in vegetables they do nothing to counteract it. If any doubt the correctness of that criticism, let them see for themselves what is practised in our vegetable markets. A. D.

FRUIT-TREE PRUNING.—As a grower of fruit

FIG. 102.—NARCISSUS HOMESPUN: PERIANTH OF A LEMON SHADE OF YELLOW, CROWN OF DEEPER TINT. (See also p. 242.)

CHOU DE RUSSIE (see fig. 104, p. 242).—If Messrs. Jas. Carter & Co. will Anglicise the name of this new winter green and call it Russian Kale, it is probable that this would greatly tend to popularise it. Since the recent R.H.S. meeting when such remarkable samples of this Kale were seen, I have had the pleasure of tasting its sprouts cooked, and can verify the opinion passed upon it by Mr. S. T. Wright, who stated that, having had some cooked, he found it to be exceptionally good. No doubt there will be a big demand for it especially in localities where winter greens of the ordinary type are apt to suffer from hard weather. Whenever it becomes a market green is it too much to ask of the trade that they will depart from the common practice in relation to Kales of cutting them whole, and thus sending to market a great quantity of inedible matter, but instead to gather the stout leafy stems into neat bunches of one pound and two pounds in weight, binding each with raffia, and so sending them to market. What a revolution in Kale market-

trees, especially Apples of the best English, French, and Russian varieties, I have long come to the conclusion that the regular annual pruning of fruit trees as practised by gardeners is a mistake, that is, if quantity and quality are the desired objects. I admit that thinning is necessary every few years, that long branches should be shortened, and that cross, awkward growths should be taken out, but the annual pruning that one sees in most gardens is a mistake. Time spent in cleansing the trees from American blight, manuring, &c., is much more profitably employed. With me many sorts have not failed to crop for at least 20 years, and some seasons very heavily. Prince Albert and Bramley's Seedling are the most prolific sorts, and the trees never fail to fruit; on the former variety I have never been able to get a growth which was too strong to fruit. A local authority on the pruning and growing of fruit trees in Birmingham came to inspect my garden, and after doing so exclaimed: "If I had to start again I should

adopt your system, for you get twice the crop, and with half the trouble." What he calls my principle may thus be briefly summed up: keeping the trees clean, occasional thinning, manuring, and then leaving them alone. A. D., who approves of the usual system of pruning, suggests trials of the two systems. Whenever this is put to a practicable test under similar conditions and with similar sorts, I am pretty sure of the result. J. P.

SPRING BROCCOLI.—When at the Royal Horticultural Hall on March 19 I heard several statements respecting the terrible manner in which Broccoli had succumbed to frost. With us, scarcely 1 per cent. all round have failed. Our practice is to continue lifting the most advanced plants from the open ground and to place them in frames in a position sheltered

—odorus (Campernelle Jonquil) and odorus rugulosus, the last named flowering about a fortnight before the other. The bulbs are potted at the end of September, and the pots are covered with ashes in the usual way and afterwards removed to a frame, in which they remain for a fortnight about the middle of November. They are next placed in an intermediate house, where they remain till they flower. As a rule rugulosus is in flower by the middle of January. The very best bulbs can be obtained at 4s. 6d. per hundred and very good bulbs for much less. We plant them in 5 and 6-inch pots, and place as many bulbs in a pot as it will conveniently hold. Last year on one occasion we had several elevated positions to decorate. Pots of different varieties of Asparagus were intermixed with Jonquils, and the beautiful deep yellow flowers of the Jonquils were allowed to fall carelessly

WITHERING OF PLANE LEAVES.—I have no hesitation in stating that I believe Mr. Elwes is mistaken with reference to this matter. It is not fungus that is the first cause of injury to the leaf, but it is cold winds, rain, and hail storms—but chiefly winds. Both varieties he indicates are liable to be so injured, but the leaf of *P. orientalis* is tougher and smaller than that of *P. acerifolia* and therefore does not suffer so severely from wind storms. T. Challis, Wilton House Gardens, Salisbury.

FRUIT PROSPECTS FOR 1907.—I never remember (in my time of 15 years here as head gardener) seeing trees of all kinds look so promising. Apricots, Plums, Cherries, Damsons, Peaches, Nectarines, Pears and early kinds of Apples are covered with fruit buds—it is too soon to judge varieties of late Apples or Strawberries—but Currants and Gooseberries are full of flower. Birds have not been troublesome. The dry summer last year, and the short growth made by most trees, which was also well matured by the dry sunny weather, were all in favour of fruit bud formation. We have now to fear frosts which I hope will not be prevalent while the trees are in bloom. Another danger is that stone fruit may drop while stoning, owing to drought at the roots during the last summer or afterwards. A. J. Long, Wyfold Court. [Various correspondents write to the same effect, but the changes and chances are too numerous to allow of any safe prediction being uttered.—Ed.]

SOCIETIES.

ROYAL HORTICULTURAL

Scientific Committee.

APRIL 2.—Present: Dr. M. T. Masters, F.R.S. (in the chair), Dr. M. C. Cooke, M.A., Messrs. Hans Güssow, G. Massee, H. J. Chapman, A. Worsley, W. Cuthbertson, H. J. Elwes, F.R.S., E. A. Bowles, J. T. Bennett-Poë, W. C. Worsdell, G. S. Saunders, and F. J. Chittenden (hon. sec.).

Botanical Certificates.—Dr. MASTERS reported on the plant shown by Mr. Bennett-Poë at the last meeting under the name of *Thibaudia* sp. (?). The plant proved to be a hitherto undescribed species of *Agapetes*, and the name *Agapetes speciosa* had been given it by Mr. Hemsley. On the motion of Mr. BOWLES, seconded by Mr. WORSDELL, a Botanical Certificate was recommended to this plant by seven votes to one on the ground of its novelty and botanical interest. [Our illustration (fig. 101, p. 237) shows that it is by no means devoid of attractiveness from a decorative point of view.—Ed.]

Narcissus from Chili.—Mr. WORSLEY showed the flower of a variety of *N. tazetta*, the bulb of which he had received from Chili, to which country it had evidently been introduced and had escaped. Mr. ELWES said that he had been struck by the large number of South European plants which had found a congenial home in various parts of South America.

Hybrid Vallota and Hippeastrum.—Mr. H. J. CHAPMAN showed a plant which was raised from seed produced from *Vallota purpurea* crossed with pollen from a purple-flowered *Hippeastrum*. The foliage was only just beginning to develop, and was stated to be very similar to the *Vallota* in appearance. The flowers were large and white, with a rather broad greenish median vein. About 200 seedlings of this cross had been raised, all of similar habit, and all but three bore scarlet flowers; the plant shown and two others, however, had white flowers. Mr. CHAPMAN promised to show the plant again when in full foliage. The reverse cross did not result in the production of any seed.

Pollen of Phaius Hybrids.—Mr. CHAPMAN observed that when two species of *Phaius* were crossed, the pollen of the resulting plant was infertile, but the hybrids produced seed when pollinated with pollen from either of the parents. The pollen of the hybrids resulting from these second crosses was fertile.

Colletia spinosa.—Dr. MASTERS drew attention to two plants of this species shown by Mr. Smith, of Worcester, which illustrated the great variation in the form of the spinous branches with which the stems are furnished. So great is the difference that the various forms had

FIG. 103.—NARCISSUS OPEN FACE: PERIANTH WHITE, CROWN FLAT, YELLOW TIPPED WITH ORANGE-RED RING. (See page 240.)

from the north and east winds. The following varieties were grown, and the percentage of failures is given: Sutton's Early White (about 1 per cent.), Snow's Winter White (about 2 per cent.), Carter's Spring White, Mammoth (about 2 per cent.), Standwell (about 3 per cent.), Leamington (none), Model (none), Satisfaction (1 per cent.). These eight varieties now look well, and we have been cutting good heads of the three first named. One important fact in Broccoli cultivation is to have the plants hardy and well seasoned, and this is best done by transplanting them early from the seed bed and allowing them plenty of room so that they do not become drawn, for Broccoli always winters best when it is sturdy and short. W. A. Cook, Leonardslee, Horsham.

JONQUILS AS POT PLANTS.—*Narcissus odorus* or Jonquils are so little used as pot plants that I think there must be many gardeners who are not aware of their value in this direction. We always grow a good batch each of two varieties

over and intermix with the Asparagus. The effect was admired by all who saw it. A. S., Birmingham.

AN IMPOSITION.—Many amateur and cottage gardeners are imposed upon by such swindlers as the one Mr. Douglas mentions on p. 211. Their plan is to occupy a place in a local market, with a few boxes of very finely-grown seedlings (Carnations), all of which have a special name and with the colour of the flower fully described. They readily dispose of the plants at from sixpence to one shilling each to inexperienced men, who cannot detect seedlings from plants raised from cuttings or layers. I had under observation last summer several dozens of these so-named plants, every one of which was a miserable single variety. Should any of these impostors appear in our market this year with their, so-called, named varieties, I can assure them of a lively reception. V. H. Lucas.

been described as distinct species under the names *Colletia spinosa* and *C. cruciata* or *bictonensis*, but Mr. Barnes, formerly of Bicton, many years ago pointed out to Dr. Lindley that one plant occasionally bore shoots of both types. The present examples illustrated this fact, proving that the two species were really one and the same.

Diseased Potatos.—Mr. JOHN COUTTS, of Killerton Gardens, sent tubers of Potatos he had received from a cottager, showing in some cases watery black marks throughout the flesh, and in others hollowed spaces. These appearances were recognised as due to the attacks of the winter rot fungus, *Nectria solani*.

Effect of environment of Primrose Leaf.—Dr. MASTERS showed drawings made by Mr. Chittenden of a Primrose leaf collected in Jersey, and sent by Mr. F. J. Hanbury. The plant was growing on rocks by the sea coast. It was of the normal length and breadth, but about a quarter of an inch in thickness, very fleshy, and showing many of the anatomical characters common to seaside plants.

Axile proliferation in Carnation.—Mr. G. REID, of Oxshott, sent a specimen of Carnation having a well-developed bud growing from the middle of the flower, a well-known phenomenon, frequently illustrated.

Numerous other specimens of diseased plants were received and reported upon.

and 3rd prizes respectively. The exhibitors mentioned were also successful in the smaller classes.

Roses in the amateurs' classes were shown in unusually good form, notably the stand of 24 blooms staged by Mr. ERNEST BEWLEY, to whom the challenge trophy valued at £15 was awarded. The best 24 bunches of flowers from the open came from the gardens of Captain LEWIS RIALI; 2nd, the Hon. Mrs. BARRY.

Trade exhibits.—Notable among trade exhibits were those following:—Messrs. HEATH & SON, of Cheltenham, staged Carnations; Messrs. ALEX. DICKSON & SONS, Newtonards, Co. Down, displayed floral designs and Roses. A large exhibit of Narcissi, including many of the rarer forms, was set up by Messrs. HOGG & ROBERTSON, Mary Street, Dublin; and another fine display of these flowers was shown by Sir J. GORE-BOOTH, Sligo. In the large concert hall Mr. F. W. MOORE contributed Palms from Glasnevin, the chief feature of a spacious tea garden presided over by Mrs. G. M. ROSS. Mr. ERNEST BEWLEY displayed foliage and flowering plants in a semi-circular manner around the orchestra, and for which he was awarded the Society's Gold Medal, the same honour being conferred on Messrs. ALEX. DICKSON, HOGG & ROBERTSON, HEATH & SON, and Sir J. GORE-BOOTH for their respective exhibits.

ing two remarkable specimens. Under the able management of the Hon. John Boscawen, hon. secretary of the society, the arrangements left nothing to be desired.

The best collection of 30 varieties of Daffodils in commerce.—1st Prize, Mrs. WALKER TYACKE, with a fine stand of the best varieties, large in size and very fresh, especially strong in the parvi-coronati section.

The best collection of 30 varieties of Daffodil, either in commerce or not.—This is always the most interesting class in the exhibition, as the stands invariably contain many new seedlings of exceptional merit. Mr. J. C. WILLIAMS staged a very fine collection, including Monarch, Lady Margaret Boscawen, Pilgrim, White Queen, King Alfred, Homespun, and 23 unnamed seedlings. Unfortunately, this stand contained 29 instead of 30 varieties, and was therefore disqualified, the 1st prize being awarded to Mr. P. D. WILLIAMS, whose stand included Hero, Jasper, Circlet, Bullfinch, Yvette, Horace, Alsace, Ibis, Peregrine, Blood Orange, Gulden, Antoinette, Cassandra, Fulgens, Juno, Chaffinch, Incognita, and Miss Mary. This stand was remarkable for the excellent condition of the flowers, and Horace and Peregrine were given Awards of Merit.

Numerous classes were provided for the various sections of Narcissus, among which we can only note the following:—

FIG. 104.—KALE "CHOU DE RUSSIE," AWARDED A FIRST-CLASS CERTIFICATE BY THE R.H.S. AFTER TRIAL AT WISLEY.

(See pp. 192-195 ante., also p. 240.)

ROYAL HORTICULTURAL OF IRELAND.

APRIL 4, 5.—The somewhat early dates, on which the spring show of the above society was held, in the Royal University, Dublin, seemed to suit the season of the Daffodil, large groups of which were staged in the entrance hall. The show, which was opened by his Excellency the Earl of Aberdeen, K.T., was a bright and attractive one, the numerous classes being generally well filled.

In the class for nine pot Roses, the premier prize of a challenge cup was won by H. S. GUINNESS, Esq., who also led in the class for the best table of foliage and flowering plants. The best display of Exotic Ferns was exhibited by Mr. W. V. WESTBY. There were, in addition, 20 classes for plants in bloom ranging from Azaleas to Narcissi in pots, and among the exhibits Mignonette was an especial feature. The principal prize for cut Daffodils was a challenge cup. This was offered for 50 distinct varieties, and was taken by C. M. DOYNE, Esq., Wexford; Mr. REGINALD T. HARRIS securing the 2nd prize. Mr. DOYNE also won the Barr Daffodil Cup offered for the best 30 varieties of Daffodils; and in this class Sir ROGER PALMER and Miss G. C. WHITE were awarded the 2nd

THE CORNWALL DAFFODIL AND SPRING FLOWER SOCIETY.

APRIL 5.—This society opened its eleventh annual show on the above date in the Market Hall at Truro. Owing to the bitter weather experienced during the past winter, it was thought that the exhibition would be a poor one, but, fortunately, these fears proved unfounded, the entries exceeding those of last year by thirty. Daffodils being very late this season, some varieties that usually grace the show-bench were missed, but a large number of beautiful flowers were staged, including many seedlings of exceptional merit, that were triumphs of the hybridiser's art.

Hard-wooded, flowering shrubs, in spite of the backward season, were present in greater numbers than ever before, the new class for Acacias producing some pretty exhibits. In the classes for hardy unforced spring flowers a great advance was made, there being 12 entries, all of high merit, many rare and beautiful flowers being exhibited, though, for the first time for some years, the New Zealand Forget-me-not, *Myosotidium nobile*, largely grown in this county, was absent. Among the new classes were two for cut Roses, one for species of Primula, and one for Rhododendron plants, the last produc-

ing the finest bloom of Parvi-coronati section in commerce.—1st prize, Mr. E. H. WILLIAMS, with Incognita.

Finest bloom *N. poeticus* in commerce.—1st Prize, Mrs. W. TYACKE, with Horace.

Finest bloom of English-raised Magni-coronati, not in commerce.—1st Prize, Mr. P. D. WILLIAMS, with Michael, a cross between King Alfred and Emperor.

Finest bloom of English-raised Medio-coronati, not in commerce.—1st Prize, Mr. P. D. WILLIAMS, with Pure Gold, a well-shaped but rather small flower of deep yellow tint, excellent in shape.

Finest bloom of English-raised Parvi-coronati, not in commerce.—1st Prize, Mr. J. C. WILLIAMS, with a twin-flowered, unnamed seedling, white with orange-scarlet cup. Mr. P. D. WILLIAMS' 3rd prize Medusa, a very similar flower, was thought by some judges to surpass the winner of the 1st prize in excellence.

Finest bloom of English-raised *N. poeticus*, not in commerce.—1st Prize, Mr. P. D. WILLIAMS, with Kestrel, very fine.

Group of Daffodil seedlings that have not been in commerce more than four years.—1st Prize, Mr. C. DAWSON, with Bernardino, Homespun, Pilgrim, a smaller and paler Homespun,

(Award of Merit), Red Eagle, white perianth, spreading orange-scarlet cup, and Circlet.

Collection of 12 hardy spring flowers.—1st Prize, Mr. P. D. WILLIAMS, with *Caltha polypetala* (First-Class Certificate), *Iris Willmottiana*, *I. tuberosa*, *I. orchoides*, *Tulipa Fosteriana*, *Trillium californicum*, *Muscari Szovitzianum*, *M. Heavenly Blue*, *Chionodoxa grandiflora*, *Anemone blanda*, *Primula denticulata*, *Trillium californicum*, *Saxifraga ciliata*.

Collection of six hardy spring flowers.—1st Prize, Rev. A. T. BOSCAWEN, with *Fritillaria obliqua* (First-Class Certificate), and *F. verticillata*.

Anemones, *Primroses*, *Violets*, and other spring flowers were shown by various exhibitors.

Finest plant of *Rhododendron*.—1st Prize, Mrs. J. P. ROGERS, with *R. suave*, 6 feet across, a sheet of bloom.

Best group of *Rhododendron* blooms.—1st Prize, Mr. R. FOX, whose success was due to two perfect and enormous trusses of *Pink Pearl*.

Six cut trusses of *Rhododendrons*.—1st Prize, Mr. D. H. SHILSON.

Six cut trusses *Rhododendrons* under glass.—1st Prize, Mr. R. FOX.

Other classes were devoted to single trusses and to *Camellia* blooms.

Three vases *Acacias*.—1st Prize, Mr. C. HEXT, with *A. Drummondii*, *A. Riceana*, and *A. dealbata*.

Twenty varieties hard-wooded flowering shrubs.—1st Prize, Sir ARTHUR VIVIAN.

Six varieties hard-wooded flowering shrubs.—1st Prize, Mr. W. H. SPOTTISWOODE.

Mr. J. C. DAUBUZ and Mr. H. H. WILLIAMS exhibited collections of Apples not for competition; Capt. PINWILL contributed an interesting collection of flowering shrubs and herbaceous plants, including the curious *Euphorbia Wulfenii*. Mrs. H. COCK sent a large pan of *Cœlogyne cristata*, 3 feet across, in superb bloom; Mr. P. D. WILLIAMS was given an Award of Merit for a collection of *Primroses* and *Polyanthi*; Mr. D. H. SHILSON took an Award of Merit for *Rhododendron Duchess of Connaught*, and Mr. K. C. CHETWOOD-AITKEN a similar award for *Acacia pubescens*, while Mr. J. C. WILLIAMS received a Cultural Commendation for his disqualified stand of *Narcissi* and Mr. R. FOX was allotted the same for *Rhododendron Pink Pearl*.

TRADE EXHIBITS.

Nurserymen's exhibits were especially good, and added much to the display of floral beauty that brightened the great hall.

Messrs. R. VEITCH & SON, Exeter, whose stand was very highly commended, received First-Class Certificates for *Magnolia Soulangeana nigra*, *Clematis montana rubens*, and *Nephrolepis todeoides*, and an Award of Merit for *Acacia cultriformis*. Among the plants staged were *Erica arborea*, *E. lusitanica*, *E. Veitchii*, *Doryanthes Palmeri*, *Correa cardinalis*, *Tricuspidaria dependens*, *Buddleia asiatica* (very fragrant), *Grevillea alpestris*, *G. sulphurea*, *G. rosmarinifolia*, and *Exochorda Alberti macrantha*.

The DEVON ROSEY, Torquay, had a fine display of pot *Roses* in full bloom, including *Souvenir de Gabrielle Drevet*, *Meta*, *Liberty*, *Mme. Chedane Guinoisseau*, *Mme. Ravary*, and *Earl of Warwick*, very highly commended.

Messrs. BARR & SONS showed a representative collection of *Daffodils*, included in which were *Peter Barr*, *Mrs. G. H. Barr*, *Princess Maud*, *Constellation*, *The Sisterhood*, *Dandy Dick*, *Golden Glow*, *Fairy Queen*, *Horace*, *Cassandra*, *Blackwell*, *Admiral Makaroff*, *Bridal Veil*, *Blood Orange*, *Calpurnia*, *Strongbow*, *Isolde*, *Duke of Bedford*, *Ariadne*, and *Monarch*. This stand was very highly commended, as was that of Mr. G. REUTHE, who showed a very interesting assortment of plants, among which were *Shortia galacifolia*, *Soldanella alpina*, *Orchis Robertiana*, *Erythronium purpurascens*, *Eriostemon myoporoides*, *Lithospermum rosmarinifolium*, *Chionodoxa gigantea alba*, *Calypso borealis*, *Fritillaria aurea*, *F. citrina*, *Bongardia Ranwolffii*, *Daphne Blagayana*, and *D. sulphurea*.

Messrs. CUTBUSH & SON were very highly commended for their stand, which contained *Iris Haynei*, *I. Susiana*, *I. Korolkowi*, *I. bucharica*, *Phlox amœna*, *Anemone alpina*, *Primula denticulata*, *Iberis gibraltaria*, *Antirrhinum glutinosum*, *Rhododendron Metternichii*, *Daphne Genkwa*, *D. altaica*, *D. gnidium*, *D. cneorum*, *Menziezia empetrifolia*, *Trillium Snow Queen*,

Andromeda polifolia alba, and *Bletia hyacinthina*.

Mr. ROBERT SYDENHAM received a Cultural Commendation for a collection of *Tulips*, *Narcissi*, *Hyacinths*, and *Lilies of the Valley*, grown in jars without drainage, in a compost of moss-fibre and pounded shell, a valuable method of culture where flowers are required for indoor decoration.

NOVELTIES.

The following is a selection of some of the more noteworthy from the newer seedling *Narcissi* shown:—

Homespun (Engleheart), a very large circular flower of "Princess Mary" form, uniform soft-lemon yellow, exceedingly solid and symmetrical. Probably the finest short-crowned yellow *Narcissus*. This appeared on several stands. (See fig. 102).

Mr. J. C. WILLIAMS showed several first-class novelties. In particular, No. 601, with the perianth white, very ample and shapely, the saucer eye of flame red with orange centre; No. 594, somewhat similar, but with crown of lighter orange; No. 593, an immense flower of the "Lady Margaret Boscawen" type, pearly white voluminous perianth, large, light yellow cup; No. 46c, a remarkable hybrid of triandrus, of soft lemon-citron, exquisite in refined colouring; No. 42b, a very choice ivory white *Leedsii*, apparently overlooked by the judges, medium-sized, quite circular and solid, with shallow crown.

Though not large, yet for excellence of form and colour a flower shown by Mr. P. D. WILLIAMS, and well named "Pure Gold," was, perhaps, the gem of the show. This evidently has triandrus blood in it, and resembles a small incomparabilis, but with long, slender tube. The entire flower is of pure and brilliant yellow.

Circlet (Engleheart) is a notably round and flat *Narcissus* of model form. *Armored* (Engleheart) is a flower of unusual but very attractive colouring. Perianth large and spreading, clear white; broad, flattened eye of salmon-orange, with velvety-green centre. *Incognita* is of much the same tones, but with more of apricot in the eye. The number of triandrus hybrids in the show proves that raisers appreciate the refined quality given by this little species. There were also several good seedlings shown between *N. Tazetta* and *poeticus*.

The poeticus forms were scarcely in bloom at the date of the show, but a few good flowers were shown of Mr. Engelheart's varieties, such as *Horace*, *Cassandra*, *Herrick*.

Several good new *Ajax* forms were shown, especially by Messrs. J. C. WILLIAMS and P. D. WILLIAMS, the latter gaining the 1st prize for this class with a very shapely and well-coloured yellow trumpet.

Obituary.

NEIL GLASS.—This well-known Scotch gardener, who for nearly 40 years was in the service of the late J. C. Bolton, Esq., of Carbrook, Larbert, passed away on the 7th inst., in his 78th year. Deceased was a type of the rugged Scotch gardener, thorough in all his ways and studying in all things the interests of his employer. He was a keen competitor at the Edinburgh and Glasgow Horticultural Shows, and was a noted cultivator of vegetables. He retired from active service about three years ago, and at the time of his retirement he received from a large number of his friends a token of the great respect in which he was held. R. L.

SIR FREDERICK W. WIGAN, BART.—It is little more than a month since we recorded the death of Sir Frederick Wigan, an enthusiastic cultivator of *Orchids* at *Clare Lawn*, *East Sheen*, and now the death is announced of his son and heir, Sir Frederick W. Wigan, at the age of 48 years.

LEO FARMAR.—The death, by suicide, is announced from *Southsea*, of Mr. Leo Farmar, a young man (28 years) who at one time was an assistant in the *Royal Botanic Gardens*, *Glasnevin*, which place he left in order to go to the *Royal Gardens*, *Kew*. Deceased, who has occasionally contributed to these columns, was employed on the herbarium staff at *Kew* for several years, in the capacity of preparator. He left *Kew* in January, 1906, and accompanied as botanist an expedition

sent out under the auspices of the *Liverpool University* to the *French and West African Colonies*. A note on this expedition appeared in the *Journal of the Kew Guild* for 1906. He was to have joined an expedition to *Africa*, arranged by Sir Alfred Jones, for the purpose of investigating the cotton-growing possibilities of that country.

ENQUIRIES AND REPLIES.

Will some reader oblige me with hints as to the cultivation of *South African Droseras*, such as *D. capensis*, *hilaris*, and *spatulata*? F. D.

STANDARD BAYS.—Can any reader explain why *Standard Bays*, after doing well for a year or so after purchase, commence to "bark" up the stem and branches, and the foliage to die? I have potted them in good loam, also loam and peat. They are well protected in the winter under a shed, and the stems are wrapped with haybands. They have not been dry at the roots. H. T.

Can any reader inform me of any special plan for making a pond to hold water? The one in question was filled last autumn from a water company's mains, but is now nearly empty, and we propose to clean it out and well puddle it for a depth of some 6 inches with clay of a greasy and adhesive texture. Will this be likely to prove effectual, concreting being out of the question? W. J. G.

ANSWERS TO CORRESPONDENTS.

* * The Editor will be glad to receive, for consideration, large photographs of horticultural subjects, suitable for forming Supplementary Illustrations to this Journal.

CAPITAL FOR COMMENCEMENT OF A BUSINESS:

Starter. There are two ways open to you to start in the business of growing *Cucumbers* and *Tomatos* for market. The first is to rent an acre or so of ground, on which there are half a dozen or more low, narrow, well-heated glasshouses suitable for growing *Cucumbers* in. See that the houses are in good order before taking them on a lease for three years with the option to renew the lease for seven or fourteen years on the same terms at the end of three years. Your present capital (£100) would enable you to do this, and with good cultural management and hard work, perhaps place you in a position to purchase an acre or more of ground and erect thereon a few glasshouses at the expiration of three years. Or with the amount of additional capital which you can command you could purchase the land and erect from four to six *Cucumber* houses on it, the number of houses being determined by their length. Houses from 100 to 150 feet long and 12 feet wide are of suitable length the latter length being preferable where the shape and run of the ground will permit. A No. 2 horizontal, tubular or sectional boiler (*Robin Hood*, *Quorn*, *White*, *Rose*, &c.), capable of heating 3,000 feet of 4-inch pipe, would efficiently heat a block of six *Cucumber* houses 100 feet long and 12 feet wide each, or four houses of 150 feet by 12 feet, but the first-mentioned heating apparatus is generally used in the heating of commercial glasshouses. All do the work required of them thoroughly when properly set and stoked. Four rows of pipes should be fixed in each house. You cannot do better than put yourself in communication with a good horticultural builder and hot-water engineer, who has a reputation for the building and heating of glasshouses suitable for the production of *Cucumbers* and *Tomatos* for market, stating what you desire, and what is your financial position. You should, however, retain one-third of the capital at your command for working expenses. One man who knows his work and is quick about it would manage the above-mentioned blocks of houses planted with *Cucumbers* (600-feet run), if occasional help is afforded when the plants are in full growth in preparing and wheeling in soil for top-dressing the ridges as soon and as often as the roots push through the mould. A man who is young and strong and working for himself can get through a lot of work during the interval elapsing between sunrise and sunset in April and five

following months. We may add that it is desirable to select a situation in a good, central district, and near to a railway station, and where a fairly good supply of water is obtainable. In the event of having to send your produce to Covent Garden Market, the Great Eastern Railway Co. afford specially cheap rates for the transmission thither over their system, of produce grown in the eastern counties, and also for the conveyance of manure thereto from the metropolis—advantages which should have due consideration by anyone thinking of embarking in the business of market gardener. In erecting a block of any number of cucumber houses only outside and end continuous walls are required, the rafters of the intervening houses resting on plates attached to valley gutter boards, supported by 9-inch brick piers built at intervals of about 7 feet, the outside walls consisting of 4½-inch work with 9-inch piers 8 feet apart, and built flush with the inside line of work, the piers showing on the outside affording support against lateral pressure. The walls and piers, it is almost needless to say, should be on the same level lengthwise and crosswise, and be 2½ feet high (including plating) from the ground line with 7½ feet rafters, thus affording low, narrow houses in which there will be no difficulty in maintaining during severe weather a minimum atmospheric temperature of 70° in each and all the houses included in the block, with four rows of 4-inch pipes in each, two flows running alongside the piers and the returns on either side the pathway, a throttle valve being fixed in each branch flow pipe forming the connection between the bend leading from main into branch flows for regulating the circulation and due distribution of hot water in the pipes in each and every house constituting the block. Two good underground tanks should be built right across the several houses—one at the bottom (lowest end), and one in the middle, for the reception and storage of rain-water, the tanks being built on the batter in 4½-inch work and cemented throughout, inlets from glass roofs being provided, as well as overflow pipes. It will be necessary to erect a small house for raising the cucumber plants in, with a sunken pathway and 7½-foot rafters springing from wall plates resting on walls 12 inches high, walls built and heated as described above. A No. 1 4 feet 6 inches long, horizontal tubular boiler, having a heating power of 750 feet 4-inch piping, will be required to heat this house. Or you might find it convenient for the first year or two to get an established grower (should there be one living within a mile or two of the site of your place) to raise the plants for you at a small cost per 100, being careful to obtain seed of a good strain of the Rochford Market or Covent Garden favourite type. You must bear in mind that even the best private gardeners have a good deal to learn when they commence market-work, even in the growing of Cucumbers for profit, and yielding quick returns, a fact which is of great importance to the man with a small capital. Cut flowers, such as Yellow Marguerites, Sweet Peas (white, pink, crimson, and mauve), Sweet Sultan, Statice and Chrysanthemums also yield quick returns, and therefore should be grown on available land. These details may be of use to you and other readers of the *Gardeners' Chronicle* who may contemplate going in for market cultivation. There is plenty of available land in the Rochford and Rayleigh districts of Essex.

COVENT GARDEN SALESMEN: A. H. R. There are many firms in Covent Garden flower market who receive flowers to sell on commission, but at the present time supplies are very abundant. We were told on Wednesday morning by some commission agents that they had written to tell senders of some sorts of flowers to discontinue as the market was overloaded. All consignments should be sent carriage paid, and a paper in each box, with the name of the sender, and the contents stated. Among the established salesmen are Messrs. Page and Saunders, Mr. Newton, Mr. D. Ingamells, Mr. Miles, Mr. Gay, and Mr. A. Bird. There are also several others, including Messrs. Monro and Messrs. Collingridge, Mr. Frederick End, &c. A letter addressed to any of these agents at Covent Garden, London, W.C., will be delivered.

FIGS DISEASED: R. W., Leeds. The injury appears to be due to fungus disease, *Cercospora Bolleana*. Burn any leaves or fruits that show signs of the disease, and spray the remaining ones with liver of sulphur, 1oz. to a gallon of water.

FRUIT CULTURE: C. F. If, as we gather, you know nothing about the industries you mention, we can only recommend you to study for some two years or more at Reading College, the R.H.S. garden, at Wisley, or some similar institution, and then to enter some fruit-nursery for some months to learn the routine.

GARDENING IN THE COLONIES AND AMERICA: G. N., A. S., and others. We have nothing further to add to the information afforded by Mr. Harry Bunyard on p. 191. You may write to Mr. Bunyard at the address given. Gardening in colonies that are only partially developed is chiefly of a commercial kind, for it is only in the big cities and more settled parts of a new country that much attention is given to private and pleasure gardening. Much useful information about Canada and its value as a field for emigration can be obtained free from the Agent-General for the colony, whose address is 17, Victoria Street, London. There is also a general Government Emigrants' information office, 81, Broadway, S.W. As a rule it will be found that success after emigration will depend upon the ability of the emigrant to adapt himself to conditions to which he is unaccustomed, and to his willingness to undertake, if needs be, work of a somewhat different nature to that he discharged before emigrating.

GOOSEBERRY CATERPILLARS: E. T. D. The common Gooseberry caterpillar (*Abraxas grossularia*). Spray the plants with an arsenical poison, such as Paris Green or London Purple, at this season, but not when the fruits are nearing the ripening stage.

GRAPES FROM SOUTH AFRICA: Wood & Co., Provision Merchants, Cape Town. The box of Grapes sent us through Messrs. Garcia, Jacobs, & Co., Covent Garden, were in a satisfactory condition and had berries were not numerous. The flavour, a pronounced Muscat, was good, the berries were large enough to constitute a good sample, and the quality was much better than that of the ordinary type of Cape or most of the Colonial Grapes sold in the fruiterers' shops. We suggest, however, that they were packed a trifle too green, for the few berries that were amber-coloured and riper were much the better flavoured. To send them in a riper condition would necessitate the use of a finer and softer wood-wool as a packing material, but as the coarser material is more elastic this could be used to line the case in the first instance. If a regular supply of such Grapes could be sent to the English markets during the early months of the year, when home-cultivated fruit is exceedingly scarce, no fear need be entertained as to their not meeting with a good demand.

HYACINTHS: W. C. The flower-spike has been growing too fast in proportion to the scales, so that it gets nipped by the scales of the bulb which do not separate as they should to let the spike through. It is not uncommon, but it is difficult to suggest a remedy. Cases have been more frequent than usual this season, which may be due to the extra warm weather in the last week of March.

MILDREW ON VINES: J. S. This fungus generally appears as the result of a cold, moist atmosphere, or of draughts, and as the viney has been used for bedding plants we suspect the watering of these has had something to do with the appearance of the mildew. You have applied sulphur to the pipes but this needs care, and should be done when the atmosphere is very dry, and at sunset. Mix a quantity of sulphur with some lime-wash, and apply it to the pipes when they are very hot, but do not let the atmospheric temperature in the viney exceed 82°. Keep this high temperature for about two hours, and gradually lower it and afford a little ventilation. Repeat this on two or three evenings, and ventilate rather freely on the following days.

ORCHID "SPOT": J. B. The specimen of *Dendrobium densiflorum* sent is affected with the well-known "spot" or Orchid disease. It appears more often in what are known as evergreen *Dendrobiums* than in those which lost their leaves during a resting season, which, in

their case, is duly observed. The evergreen varieties do not show by the leaves turning yellow that they require a cooler and drier resting period, and consequently they are too often kept in much heat all the year, and disease, similar to that shown on your specimen, is the result. Give this section, in future, a reasonable resting period when the bulbs have matured each season.

NAMES OF FLOWERS, FRUITS AND PLANTS.—We are anxious to oblige correspondents as far as we consistently can, but they must bear in mind that it is no part of our duty to our subscribers to name either flowers or fruits. Such work entails considerable outlay, both of time and money, and cannot be allowed to disorganise the preparations for the weekly issue, or to encroach upon time required for the conduct of the paper. Correspondents should never send more than six plants or fruits at one time: they should be very careful to pack and label them properly, to give every information as to the country the fruits are grown in, and to send ripe, or nearly ripe, specimens which show the character of the variety. By neglecting these precautions correspondents add greatly to our labour, and run the risk of delay and incorrect determinations. *Correspondents not answered in one issue are requested to be so good as to consult the following numbers.*

PLANTS: H. V. Both forms of *Cupressus Lawsoniana*.—L. G. P. *Lavandula Stoechas*, a common plant in the Mediterranean region, sometimes called in England the greenhouse Lavender.—C. S., Glasgow. *Selaginella rupestris*.—G. L. F. *Gagea lutea*.—R. C. should address such questions to the editor and not to the publisher. 1, *Primula verticillata* var. *simensis* (not *sinensis*); 2, *Lopezia racemosa*.—M. M. A very fine variety of *Odontoglossum Rosii* majus. —V. O. 1, *Oncidium cheiroporum*; 2, *Oncidium ornithorhynchum*; 3, *Masdevallia trianstellata*.—W. H. C. It is very difficult to name *Codiaeums*, or *Crotons* as they are called, from leaves, the variation on the same plant, as shown by some of your specimens, being very considerable. 1 appears to be *C. pictum*; 2, *C. Mortii*; 3, *C. Evansianum*; 4, *C. trilobum*; 5, *Cordylone (Dracena) Baptistii*; 6, *Cordylone (Dracena) terminalis*.—E. C. D. *Chlorophytum elatum variegatum*. A liliaceous plant, allied to *Anthericum*. It is grown in greenhouses and stoves, for the sake of its long, narrow, but rather thick leaves, which are green and white. —T. O. J. You send more than the number of specimens allowed, and it is against our usual practice to attempt to name varieties of florists' flowers. A donation for the Gardeners' Orphan Fund would be appropriate. 1, bicolor Empress; 2, incomparabilis Sir Watkin; 3, incomparabilis Stella; 4, incomparabilis, a discarded variety; 5, Leedsii Duchess of Brabant; 6, Barrii Orpheus; 7, Burbridgei Baroness Heath; 8, poeticus ornatus; 9, Henry Irving; 10, Leedsii Palmerston; 11, Johnstoni Queen of Spain; 12, Tazetta, common Mediterranean species. The two unnumbered are Burbridgei John Barr and R. Barr. —T. W. *Gerbera Jamesoni*. Some improved hybrids of various colours are obtainable, and you would do well to procure them. —F. R. 1, *Dendrobium chrysotoxum*; 2, *Erythronium dens-canis*; 3, *Pulmonaria officinalis*; 4, *Acacia armata*; 5, *Scilla siberica*; 6, *Scilla bifolia*. —X. Not *Abies Nordmanniana* but *A. Pindrow*.

PELARGONIUM LEAVES: B. P. The spotting is probably caused by excessive moisture and deficient ventilation. No fungus is present.

SWEET WILLIAM DISEASED: E. H. The plants are badly infested with a fungus disease, *Puccinia Dianthi*. Burn the entire stock of seedlings, and spray any Carnations or Pinks growing near them with liver of sulphur, using half ounce to one gallon of water. Perhaps it is by means of these last-named plants that the disease has been transmitted. Next year's batch of seedling Sweet William should be sprayed with liver of sulphur at intervals.

VINE WEEVIL: A. A. The specimen is one of the commonest of the weevils. Trap them with slices of some vegetable, such as carrot or potato. They are best caught at night time, for they feed in the dark.

SPRING WORK IN FRUIT PLANTATIONS.

A GENERAL SURVEY.

WHAT a blessing it is that birds have hardly touched a Plum bud this season! Last year, after a mild winter, they played havoc with trees on the outside of my Plum plantation, eating both fruit and leaf buds wholesale, and to an extent quite deforming the trees attacked. Now, on April 8, the leaves are expanding, and the blossoms are on the point of coming out on some varieties, Monarch, my latest for fruit ripening, being first, or about abreast with Black Diamond, as usual. The trees are now safe against birds, although they have not been sprayed. So are Gooseberry bushes in all but a small piece of land near the homestead, where they were attacked about the middle of December, but not again after they were sprayed with lime, sulphur, soft soap, and caustic soda. The rest were sprayed on January 18 and 19, as a slight attack on some outside bushes was noticed on the 17th. No damage has been done since. Last season the injury to the bushes from bud-eating birds was very serious.

It would be interesting if other growers of Plums and Gooseberries would relate their experience as to bud-eating birds during the present season. If the exemption noticed above has been common where no spraying has been done, any suggestion as to its probable cause would also be interesting.

SPRAYING.

As the birds left my Plum trees alone, the expense and trouble of spraying them with a preventive wash have been saved. Almost every day since the leaf-buds began to swell the trees have been examined in order to see if the aphid has appeared. The viviparous females are about due, and it is important to spray them before they reproduce their species; for, if they are not destroyed, their young will soon be swarming over the trees, safely ensconced in curled leaves. Only a solitary specimen has been found at present; but it seems too much to hope that there will be an exemption from aphid attack, as well as from bud-eating.

Apple trees have been sprayed recently, just before the fruit buds burst, with 4 lb. of copper-sulphate to 100 gallons of water, as a preventive to scab. When the blossom has fallen a second spraying will be given, Bordeaux mixture being used; and a third will follow a fortnight later. Scab, as well as the aphid, did an enormous amount of damage in my plantations last year.

If the aphid or the Apple-sucker, or both, should appear, both Apples and Plums will be sprayed with Bordeaux mixture and paraffin, the former as a preventive to scab in Apples and leaf-blight in Plums, and the latter to kill the aphid and the Apple-sucker. As paraffin emulsifies with Bordeaux mixture, the combination should be a safe one, or as safe as any effective spray-stuff is, absolute safety being out of the question. Only two gallons of paraffin will be included in a hundred gallons of the wash for use when the foliage is tender, and possibly three gallons when the leaves are fully expanded, if any seems to be needed then. Mr. Walter Collinge used as much as six gallons in a hundred in his paraffin emulsion last year, with only slight damage on a second application to Plum trees—"really nothing worth noting," he says. But I am very apprehensive of the action of paraffin on foliage. If I sprayed for the insects alone, I should prefer a wash composed of 12 lb. each of soft soap and quassia to 100 gallons of water.

Where caterpillars are troublesome, 3 lb. of arsenate of lead should be added to the 100 gallons of wash, if they put in an appearance, or, in any case, after the blossom has fallen, if the Codlin moth caterpillar is usually present in the plantation. In my isolated situation the pest last named has not been encountered.

SPRING PRUNING.

The advantage of leaving newly-planted Apple trees to be cut back at the beginning of April has been obvious when the work was done. As the buds were on the point of bursting, it was easy to select the most vigorous pointing in the right directions to be left just below the cutting, and to detect

the fruit buds, which are not all obvious on young trees of some varieties when they are entirely dormant. Nicely branching Golden Spires were found in many cases with fruit-buds developing all along the shoots of last year's growth, and these had to be cut back nearly to the stems, to get down to leaf buds.

One row of trees of the Lord Grosvenor variety, has been left not cut back, in order to notice the results of deferring the operation until the second spring after planting. Not being a believer in the advantage which some growers claim for this plan, I expect to find the growth of this row less satisfactory than that of the two rows of the same variety on either side of it.

STOCKS OF TREES.

Particularly noticeable is the superior growth of young trees budded or grafted on the crab-stock to that of those which were raised on the Doucin, taking the same varieties into comparison. The former are admirable specimens of well-furnished two-year-old trees, with fairly long and sturdy young branches, while the latter, particularly in cases of not very free-growing varieties, have shorter and more slender branches, less regularly and suitably placed. Lane's Prince Albert, for example, on the crab has strong growths sufficiently upright in direction, while on the Doucin its growths are of a spikey character, mostly pointing either horizontally or even downwards. Experience convinces me that the crab is the stock for trees in my fields, as those on the Paradise do not make enough wood, but tend to fruit prematurely and excessively. The Doucin was tried as an intermediate stock, but the crab will be used for the future, except for cordons, for which the Paradise will be used.

The superiority of Quince to the Pear stocks for cordon Pears is another subject of observation. The trees on the Pear stocks were not intended for cordons, but, as they seemed likely to develop fruit-spurs well from close to the ground level, some of them were planted as maidens last autumn. Not one will blossom this year, whereas nearly all the maidens on the Quince stock are showing blossom buds.

GRAFTING.

The grafting of Apple stocks is now finished. To cover the grafts, the good old mixture of clay, cow dung, and finely-cut hay chaff was chiefly used. For stocks grafted close to the ground, it seems to me preferable to grafting wax. On the whole, it gives less trouble than wax, which has to be prepared in the first instance, and heated afresh on each application. It costs practically nothing, whereas wax is expensive. As for wax that can be used without heating, it is easy enough to put on, but very troublesome to get off.

DEVELOPMENTS.

This season has been pronounced a very backward one for fruit development. It was so until after the middle of March; but the splendid weather of the last eleven days of that month and the first few days of April brought vegetation forward so rapidly that all kinds of fruit are at least as forward at the time of writing as they were a year ago. *A Working Grower, Sussex.*

NEW OR NOTEWORTHY PLANTS.

STROBILANTHES MICHOLITZI. *N. Sp.**

This is a pretty little half-shrubby plant, with lanceolate leaves, and axillary racemes of white flowers arranged in white, cones of rounded bracts. The abundant bracts give it a remarkably pretty appearance, and it is well worth cultivation. It is a native of Sumatra, where, on the east coast, Mr. Micholitz discovered it. This charming plant seems rather difficult to cultivate, as it has somewhat of a habit of dying away after flowering; but this will doubtless be obviated by Messrs. Sander, of St. Albans, who have the plant in cultivation.

It is a half-shrubby plant, 3 or 4 feet in height; stem four-angled, dilated at the nodes; leaves opposite, 6 inches long 2 inches wide, but one much larger than the other, lanceolate or ovate-lanceolate acuminate at both ends, crenulate, nerves six pairs ascending, scabrid, hairy along the nerves, beneath pubescent, hairy, petiole 1 inch long. Racemes axillary strobiliform, shortly peduncled, very numerous, $\frac{1}{2}$ to eventually $\frac{3}{4}$ inch long. Bracts rounded with a cuneate base, upper edge recurved, white tipped with green, $\frac{1}{2}$ inch long, $\frac{1}{2}$ inch wide, scabrid, at length glabrous. Flowers shortly projecting from the cone, white. Calyx base shortly tubular above, split into six linear acuminate unequal lobes, narrow, glabrous, with a mucro-like trichome projecting from the top of each. Corolla shortly funnel-shaped, lobes rounded, lower lip a little longer than upper one. Stamens projecting, four, filaments slender, much longer than the corolla, anthers oblong. Capsule ovoid, not stalked, with a tuft of hairs at the tip. *H. N. R.*

NARCISSUS DUBIUS.

THE neighbourhood of Montpellier is rich in Narcissus. On the edges of the ditches and the small streams the *Tazetta* Narcissus is especially abundant. It is also found in damp meadows, frequently in company with *Narcissus poeticus*, and crossing with this species yields interesting natural hybrids that a little while ago were introduced into trade under the name of "*Poetaz*." These hybrids are not rare in the fields of Lattes, situated some miles from Montpellier.

In my opinion, the most interesting of them all is the *Narcissus dubius* of Gouan. This is a *Tazetta* in miniature, with small, creamy-white flowers, of a delicate perfume far less penetrating than that of *Tazetta*. Instead of preferring moist situations, it is found only in calcareous and dry soils fully exposed to the sun. It grows near *Cistus Mompeliensis* and *Cistus albidus*, *Genista scorpiurus*, *Helichrysum Stœchas* and other plants in dry and sunny ground. It should be possible, given suitable conditions, to cultivate it in England. It must not be forgotten that the climate of Montpellier is decidedly cold in winter. Rarely does a year pass when the thermometer does not, on several days, fall to 10° C., or even lower (14° F.).

This *Narcissus*, if planted in calcareous soil, in a dry and sheltered position, and allowed complete rest from the end of summer to February, certainly might be grown in England.

**STROBILANTHES MICHOLITZI*, *Ridley sp. n.*—*Suffrutex tripedalis*; caule quadrangulati nodis incrassatis; foliis oppositis uno majore, lanceolatis vel ovato-lanceolatis acuminatis, crenulatis 6 poll. longis, 2 poll. latis scabridis superne hirsutis, petiolo pollicari; racemis axillaribus strobiliformibus breviter pedunculatis, plurimis $\frac{1}{2}$ — $\frac{3}{4}$ pollicis longis; bracteis rotundatis albis apicibus recurvis, viridibus; floribus breviter protrusis albis; calyce basi tubulato superne fissis, lobis 6 linearibus acuminatis inaequalibus; corolla breviter infundibuliformi, lobis rotundatis; staminibus, 4 protrusis, filamentis corollae longioribus, antheris oblongis; capsula ovoides haud pedicellata. Sumatra in ora orientali (Micholitz). *H. N. Ridley.*

If any of your readers care to make the experiment, I shall have some bulbs to offer them in exchange next autumn. *F. Denis, Balaruc les Bains, Hérault, France.*

[This *Narcissus* is figured in Parkinson's *Paradisus*, Moggridge's *Contributions to the Flora of Mentone*, plate 71 (1871), as well as in Burbidge's *Narcissi*, plate xxviii., and Coste's *Flore descriptive*, tom. 3 (1895), n. 3,555. From Moggridge's *Contributions* we cite the following interesting note:—

"*Narcissus dubius*, Gouan, is one of the grateful exceptions to the rule among *Narcissi*, for it is found in wild, rocky situations in the mountains near Toulon and Hyères, and never, as far as I know, in cultivated ground."

Mr. Moggridge remarks that the plant is very variable, and adds: "I would suggest to experimentalists that a series of observations, noting the character of seedlings from the earliest and the latest flowers of individual plants, might lead to interesting and valuable results. To make the experiments complete, both the first and the last flowers should be fertilised with pollen from a distinct individual of the same species, and should be protected from insect agency. *N. dubius*, Gouan, is not found in

FIG. 105.—*NARCISSUS DUBIUS*, NATIVE SPECIMEN: FLOWERS CREAM-COLOURED.

Italy or along the Riviera; but from Mount Coudon to the westward, at Marseilles, Avignon, Pont du Gard, and Bione, in Hérault (Gren. et Godr.), Aix, in Provence (Herb. Gay!), in Corsica, at Ajaccio (Bourgeau!), near Mont Cada about 21 miles north of Barcelona (Bourgeau! in Herb. Gay; this label and that of the preceding specimen being written by M. Gay), Pyrenees, and Greece (Nyman)."—Ed.]

FRUIT REGISTER.

LATE APPLES IN CORNWALL.

Two meritorious exhibits of Apples were made at the Cornwall show held at Truro on April 5th. J. C. Daubuz, Esq., sent from Killiow, West of Truro, 35 dishes. Cornish Aromatic is a variety which, although considered by growers in the home counties to be of second quality, is justly esteemed in Cornwall, where it usually bears well. It is a good-flavoured, angular fruit, of medium size, streaked with russet, and one that keeps well; probably in the more eastern counties this variety misses the abundant moisture of Cornwall. Newton Wonder was represented by fine fruits, and Bramley's Seedling was also

of very good shape, and well coloured. The dish of Wagener looked as if it would keep for a long time. This is a rare Apple in Cornwall; such a valuable late kind should be given a trial wherever possible. Blenheim Pippin had just begun to shrivel. The fruits of Lord Hindlip were both highly coloured, and sound. The dish of Beauty of Kent was of good size and finish, but just beginning to show signs of decay. Other noticeable dishes were Dumelow's Seedling, Alfriston (very large fruits), and Bess Pool.

From Pencalenick, H. H. Williams, Esq., sent 11 dishes of very firm, sound Apples, all of good form and very clean skin. The most conspicuous were Adams' Pearmain, Allen's Everlasting, Bess Pool, a medium-sized angular fruit, very brightly streaked with red, Boston Russet, very highly coloured, Old Nonpareil, Scarlet Nonpareil, and Sturmer Pippin. *A. C. Barltan.*

APPLE "ONTARIO."

THERE is probably no cooking Apple cultivated that retains its freshness, firmness, and exquisite flavour after being cooked as this variety does through the months of April and May. It is also a constant and prolific bearer, and is adapted for any method of training. *T. Challis, Willow House Gardens, Salisbury.*

LATE APPLES.

I ENCLOSE a fruit of each of the Apples mentioned by me on p. 223:—Bramley's Seedling, Mère de Ménage, Newton Wonder, Lane's Prince Albert, Annie Elizabeth, Tibbet's Pearmain, Blenheim Pippin, Dumelow's Seedling, and Beauty of Kent. *W. H. Collitt, Huntsham Court Gardens, Devonshire.* [These were good specimens, and in appearance as fresh as they could have been in October.—Ed.]

VEGETABLES.

EARLY CAULIFLOWERS.

IN order to have a good supply of Cauliflowers to follow the spring Broccoli, a sowing should be made at the end of August and another at the middle and end of September. These sowings should be made on good soil and in an exposed position; so that the plants will be robust. When the seedlings are far enough advanced for transplanting, they should be planted singly in firm ground where they will winter. By the time they are ready for transplanting, it will be seen which of the three sowings is best suited for the purpose. They should be planted in firm soil on a border and where cold frames or some temporary shelter can be placed over them if necessary. I believe in planting some in cold frames and others on an open plot which is protected from cutting winds. Our exposed plants this season have withstood the weather well and are as sturdy as could be desired, and can now be shifted without fear of being cut down by spring frosts. Plants that are raised and grown in heat suffer most in this respect. Good varieties for winter work are Sutton's 1st Crop, Magnum Bonum, Purity, Universal, and White Queen. As its name implies, 1st Crop is the earliest and is often ready for use before the Broccoli is finished. This Cauliflower requires using as soon as it is fit, otherwise it loses colour and soon opens and becomes unfit for the table. Magnum Bonum, which follows, is very fine and is available for a considerable time. Carter's Mont Blanc is another good Cauliflower; its "head" is well protected by foliage and the vegetable lasts a considerable time in good condition. It is particularly suitable for a heavy soil. Carter's Forerunner is an early variety of first-class quality, and one of the best for spring sowing. Carter's Extra Early Autumn Giant is useful to fill up the gap between very early and late varieties. It is more compact and a month earlier than the old Autumn Giant, and is a capital Cauliflower to withstand the drought. *W. A. Cook.*

NOTICES OF BOOKS.

GREENHOUSE AND CONSERVATORY CONSTRUCTION AND HEATING. By Paul N. Hasluck. Cassell & Company, Limited, London.

THIS small work consists of 160 octavo pages, half of which number is occupied with engravings and diagrams of various kinds of horticultural erections with sundry methods of glazing, and numerous kinds of heating apparatuses, advertisements and index. The contents are embodied in nine chapters, in which the following subjects are dealt with:—The Principles of Greenhouse Construction, Horticultural Glass and Glazing, Lean-to Greenhouses; Lean-to Conservatories; Span-roof Greenhouses, Dome-roof Conservatory; Conservatory and Verandah, Window Conservatory, Heating Greenhouses. Details in the preparation and fixing together of all portions of woodwork necessary for the erection of various kinds of conservatories, greenhouses, &c., are given and freely illustrated. Elementary instructions as to the cutting of sheet glass, and the fixing of the panes in the woodwork, with and without putty, are given and illustrated at pages 13 to 20. A chapter on heating occupies fifty-one pages of letterpress, in which are included seventy-eight illustrations and diagrams of boilers, &c., but out of the sixty-six heating apparatuses illustrated, such well-known and efficient boilers as the Thames Bank horizontal tubular, the upright tubular, the Robin Hood and others are not included. In this chapter many useful and practical hints are given regarding the most suitable kind of boiler to be used for the heating of glass structures of various shapes and dimensions, and on the making of joints in hot-water pipes, but we cannot agree with the author in his statement (p. 136) that "the rust joint is generally adopted for large work, that the rubber ring joint is also in general use, and that Portland cement is occasionally used," adding "that the practice can only be condemned." Practical experience goes to prove most conclusively that this statement is wrong, for the cement joint when properly made is the cheapest, most quickly made, most efficient, lasting, and neatest joint used for connecting lengths of hot-water pipes, and quite 90 per cent. of connections made in recent years consist of joints made of cement and rope yarn. The rust joint is quite out of date, as also are the red and white-lead putty-made joints, which the author says at page 138 "are extensively used," alternate layers of yarn and putty being caulked in, finishing off with putty." Joints made of iron borings, powdered sal ammoniac, and sulphur, red and white lead and yarn, were extensively used 30 or 40 years ago before the efficacy and simplicity of cement and yarn-made joints became generally known. The remarks on the heating of a block of six forcing houses at pp. 152-3 are clear and practical, but instead of having the cold-water supply cistern fixed near to the boiler as recommended, we should prefer having it fixed inside one of the houses at the highest end farthest from the boiler, connecting the cistern with the return pipe, making the connection with one of the recently-introduced "saddle clips," and a 1½-inch expansion pipe, instead of the 3-inch or 4-inch recommended, and this should be fixed in the front casting (whence the two flow-pipes proceed) instead of in the 6-inch main flow-pipe. This pipe should be taken up to a height of at least 12 feet above the supply cistern, with a bend or T-piece on top to prevent hot water being wasted in this direction. The author is incorrect in saying that the heat in the mains continued round to form one pair of side pipes in a block of commercial glasshouses arranged as stated at pp. 153-4 cannot be regulated by a valve without affecting the whole apparatus. It is quite essential to the securing of a proper and equal circulation and distribution of hot water in each and all of the flow-pipes that a throttle valve should be fixed in each.

THE PRINCIPLES OF HORTICULTURE. By Wilfred Mark Webb, F.L.S. Blackie & Son.

"THIS little book is intended to form an introduction to the theoretical side of horticulture, and has been written primarily for the benefit of those engaged in its practice." The requirements of young gardeners and beginners have, therefore, been mainly considered, and the author's experience as a teacher and demonstrator to garden-pupils has served him in good stead. The importance of drawing, as an aid to observation and study, is rightly insisted on. Artistic representations are not needed, and the pupil must not, in his drawings, allow his fancy to prevent him from delineating, as exactly as possible, what he sees, rather than what his imagination suggests. Exact accuracy is not to be expected, though it should always be aimed at. As the pupil's manual facility and his faculty of observation become developed, so will his sketches improve in value. It is only a small proportion of young gardeners who have the opportunity of attending technical schools and laboratories, and, therefore, only a few will be able to make use of a compound microscope, and to acquire the means of preparing objects for microscopical examination. A great deal may, however, be done with a sharp pocket knife and a magnifying glass such as no gardener should be without. With their aid not only may the construction of most flowers be readily made out, but often the nature of hairs and scales, the appearance of cells as, for instance, in the pith of the elder, the spiral vessels, the root-hairs, the pollen-grains, and various other details can be determined with facility. The text-book, or, better still, the lecturer, can explain the uses of these several parts, and thus add greatly to the interest of the practical work of the garden. To dig a vegetable quarter, water a pot plant, open a ventilator, shade a greenhouse, may be all learnt mechanically, but, unless intelligence is brought to bear upon these duties, they become mere tasks and toils to be completed as soon as possible and replaced by some more congenial, even if less profitable, occupation. Infuse intelligence into these proceedings, and what was a task becomes a pleasure. Let the gardener think of a plant as it really is, endowed with life, always at work while life lasts—feeding, breathing, growing, transmitting, manufacturing, storing—and the interest of gardening becomes enhanced. Let him bear in mind also the practical importance of recognising the effect of various degrees of moisture, heat, light in relation to the growth of plants, and the value of what some disdainfully call theory will become apparent. It is essential to be able to do a thing, but to do it well requires intelligence as well as mechanical facility. From this point of view, Mr. Webb's little book will be of great assistance to young gardeners, especially to those who have the opportunity of spending a short time in a technical school. A great deal must, in any case, be taken on the authority of the teacher. Not many of us can prove for ourselves that lime is necessary for the formation of nuclei, or potash for that of starch. These things must, in most cases, be taken on trust, and hence it becomes essential that the teacher and text-book writer should be worthy of confidence. The present work bears such a test well; the text is lucid, the illustrations instructive. Chapters on insects and insecticides are furnished, and a complete list of the natural families is given according to the system of Engler. This is in many respects an improvement on the Candolleian sequence, which was followed mainly by Bentham and Hooker. The collocation of Sarracenias, Nepenthes, and Droseras in one group, however, is made for physiological reasons only. Morphologically, these groups are wide apart. To place them together will puzzle the young gardener who can also not be expected to understand the meaning of "leptosporangiate" Ferns. The book is provided with a full index, and is one that should find a place in every garden library.

PLANT NOTES.

PRIMULA ALBA, PLENA.

THIS old garden plant is a very beautiful subject when well cultivated, blooming from early December if given a light position near the glass roof, and continuing in flower up to early March. As the plants are now past their best condition, the bottom leaves should be trimmed with a pair of sharp shears or a large pair of scissors, and the pots be surfaced with a mixture of chopped sphagnum and leaf-soil, with the addition of a little silver, or clean river sand. The new soil should be mounded well up around the stem of the plant, in order to encourage the development of new roots, so that when the plants are divided towards the end of May, each little offshoot shall be well rooted. The pots should be stood moderately close together, the most suitable place being in a north pit, and as near to the glass as convenient to prevent the leafstalks from becoming unduly lengthened. The top-dressing must be kept moist by daily damping with a rose can, both in the early morning and again in the afternoon. It is good practice to drop the pots into others of a larger size, by which means about 2 inches extra space is afforded for this surfacing, which does not get washed aside. In dividing the plants later, care is required, and a sharp knife should be used, or many of the tiny white roots will be injured. Pots 3 inches and 3½ inches in diameter will be found suitable for the offshoots. Do not press the soil too firmly at this potting, and return the plants to the pit, or place them in a frame, where they must be kept close for a fortnight and be shaded during bright weather. If the plants are watered when potted, a light sprinkling overhead with a fine rose can or with the syringe twice daily on fine days will supply all the moisture required until ventilation is given. The usual compost afforded single varieties of Primulas will suit the plant under notice, and pots 5½ inches in diameter are quite large enough for the final shift in June. J. Mayne.

BEGONIA LIMMINGHEII.

As an ornamental plant for cultivating in hanging pots and baskets, this species can scarcely be recommended enough, the abundance of its flowers making it a striking object. The plant should be grown under warm greenhouse conditions in porous, moderately rich soil. It may be increased by cuttings of 8 to 4 eyes, taken at the end of January or beginning of February.

PLANT PORTRAITS.

RHYNCANTHUS JOHNIANUS, Schlechter.—A perennial tuberous herb with sheathing lanceolate leaves, dense flower spikes, with overlapping scarlet bracts and yellow flowers. It belongs to the Zingiberaceæ. Introduced with *Thunia Marshalliana* from Moulinet to the garden of Mr. John, of Adernach.—*Garten Flora*, March 1.

IMPATIENS OLIVERI.—*Le Jardin*, March 6.

BEGONIAS, WINTER-FLOWERING.—*Garden*, March 16.

ROSE, DEAN HOLE.—H.T., pale yellow, deeply flushed with rose-pink.—*Horticulture*, March 9, 1907.

APPLE, FRIANDISE.—An early, Pear-shaped Apple, yellow, strongly flushed with red; flesh delicate, highly flavoured.—*Revue de l'Horticulture Belge*.

PEAR, BELLE GUYENNAISE, a seedling raised by M. Dion. Fruit large obovate citron yellow, flesh white, flavour excellent, comparable with that of Doyenné du Comice; season, October-November.—*Revue Horticole*, March 16.

IRIS PUMILA.—1, Die Braut (the Bride); 2, Brautjungfer (the Bridesmaid). White varieties of *Iris pumila*.—*Die Garten Welt*, March 28.

ANTHYLLIS MONTANA.—*Möller's Deutsche Gärtner Zeitung*, March 28.

PAEDEROTA BONAROTA.—*Gärtner Zeitung*, March 28.

GENOTHERA HAVARDI.—*Gärtner Zeitung*, March 28.

PENTSTEMON LINARIOIDES.—*Gärtner Zeitung*, March 28.

CHRYSOOPSIS VILLOSA VAR. RUTTERI.—*Gärtner Zeitung*, March 28.

SWEET PEAS, HELEN LEWIS and MISS AUDREY CRIER.—*Garden*, March 30.

ACACIA PODALYRIIFOLIA.—*Revue de l'Horticulture Belge*, April 1.

CORIARIA TERMINALIS.—*Revue Horticole*, April 1; *Gard. Chron.*, 1908, part ii., p. 282, fig. 119.

HYPERICUM CALYCINUM, PATULUM, PERFORATUM and ELIODES.—*Gardener*, March 30.

FOREIGN CORRESPONDENCE.

ERYNGIUM PROTEÆFLORUM.

This very remarkable species is undoubtedly one of the best of recent introductions. The plant is quite different in general appearance from the Eryngiums of the Old World. It is somewhat like a Bromeliad in appearance, and in habit resembles the Eryngium of the Andes of South America.

Mr. C. A. Purpus first collected it in the sub-Alpine region of Mexico, where it occurs near the tree-limit, at an elevation of between 11,000 and 14,000 feet, in damp situations, and often in close proximity to *Pinus Hartwegi*, the Pine that is found at the greatest altitude in that district. It was also discovered growing, often in masses, on open grassy spaces and amongst rocks.

shoot bears at the end one or two flower-heads, which spring from a silvery-white sheath having a diameter of from 7 to 8 inches. The flower-heads are light blue, 2 to 3 inches long, and fully $1\frac{1}{2}$ inches across. These blue flowers, enveloped in their broad, silvery-white sheaths, produce a beautiful contrast of colour. The flowering begins in August and continues till winter sets in.

No special culture is necessary for this Eryngium. Loamy, peaty soil, with leaf-mould, and a somewhat damp situation, suit the plant best. It is very suitable for setting in groups on a rockery, and also looks well when planted singly on turf. The plants are specially valuable as producing an effect that is as striking and uncommon as it is beautiful. Their natural growth in elevated, mountainous regions renders

your opinion (p. 204)—“the abundance, and especially the quality, of the crop, which are the first considerations.”

With regard to present size of pruned and unpruned trees, our results mainly agree with those given by Mr. Pickering, with Apples, Pears, and Plums severally, the difference between the pruned and unpruned Plums (*The Czar*) being nearly 100 per cent. Pears (*Williams' Bon Christian*) also show a great difference in size between the pruned and unpruned trees. Apples (*Lane's Prince Albert*) show the least difference, but it is clearly defined. The trees of each kind of fruit only slightly pruned are intermediate in size.

But is this difference in size after a period of only eight or ten years remarkable? Considering that properly-pruned bush trees (the

FIG. 106.—ERYNGIUM PROTEÆFLORUM, A NEW SPECIES FROM MEXICO: LEAVES SILVERY-WHITE.

Eryngium proteæflorum grows as a spreading bushy herb, from 12 to 16 inches high, the flower spikes rising to a height of some 3 feet.

The linear leaves are of a silvery-green colour, from 19 to 24 inches long, and from half an inch to 1 inch wide. They diminish to a point at the tip, and are furrowed lengthwise with fine white ribs. On both edges of the leaves are set, about half an inch apart, white spines, each about three-quarters of an inch in length. They form patches of white, and so produce a striking contrast with the silvery-green of the leaves.

The leafy flower spikes average 3 feet in height. They are much-branched, and each

them tolerably hardy, and only in the northern and colder districts of Europe will the plants need protection in the winter. This fine species of Eryngium has been introduced into commerce by Mr. C. Sprenger, of Vomero, Naples. A. Purpus, *Inspector of the Botanic Garden of Darmstadt*.

PRUNING AND NON-PRUNING OF TREES.

My annual report on the county experimental garden here being yesterday received from the printer, I hasten to send a copy to you, because on pp. 12-18 you will find results confirming

above remarks apply to bush trees only) annually have from a half to three-fourths of their total growth removed at the summer pruning or winter pruning, or at both, how can they become so large in a restricted time as unpruned and equally healthy trees growing under equal conditions in all other respects? It would be as reasonable to expect a man who took two or three steps backward out of every four paces he took forward to reach his goal in the same time as a man of equal speed who marched straight to the goal. But with regard to the amount of wood annually removed from the pruned trees, if they were credited with the length and weight

of these prunings, there can be no doubt that the pruned trees would easily be first in size and weight. The latter statement is in accordance with your statement—and all my experience in pruning fruit trees—and bears out your opinion "that pruning does increase the production of new wood." *J. Udale, Droitwich.*

EXTRACTS FROM MR. UDAL'S REPORT.
RESULTS OF EXPERIMENTS IN PRUNING AND NON-PRUNING.

"These experiments annually increase in value and interest. Eleven trees of Apple Lane's Prince Albert are growing under equal conditions in all respects except in regard to pruning.

Five trees in one row have been annually and carefully pruned. Three trees in the next row have been annually and badly (or roughly) pruned; and three trees in the same row have not been pruned.

—of the fruit, in November we carefully selected 28 lb. of the largest Apples from each stored sample (the whole of the fruit), with the following results after careful counting:—

70 Apples from the well-pruned trees weighed 28 lb.

125 Apples from the badly-pruned trees weighed 28 lb.

170 Apples from the non-pruned trees weighed 28 lb.

When sold in the wholesale market they realised the following prices:—

Fruit from well-pruned trees (first grade) 10s. nett per cwt.

Fruit from well-pruned trees (second grade), 8s. 4d. nett per cwt.

Fruit from badly-pruned trees, 5s. 10d. nett per cwt.

Fruit from non-pruned trees, 4s. 10d. nett per cwt.

For the purpose of this report the above fruit

near future is almost a foregone conclusion in favour of good pruning.

The following respective weights of Apples have been gathered from the garden:—1898, 101 lb.; 1899, 143 lb.; 1900, 414 lb.; 1901, 957 lb.; 1902, 250 lb.; 1903, 566 lb.; 1904, 5,862 lb.; 1905, 1,706 lb.; 1906, 4,652 lb."

THE ALPINE GARDEN.

CHIONOSCILLA "THE QUEEN."

CHIONOSCILLAS—hybrids between the Scillas and the Chionodoxas—are seldom met with, for they do not appear to be numerous enough to be offered in commerce. Natural hybrids have been found, but the finest in cultivation are those raised and named by the late Mr. James Allen, of Shepton Mallet, the most distinct of the set, mainly on account of its colour, being the one named above. It is a hybrid between *Scilla bifolia*, probably the white form, and

FIG. 107.—FLOWERS OF *ERYNGIUM PROTEÆFLORUM*: FLOWER-HEADS LIGHT BLUE.

These were planted in 1899 on the same day as those undergoing the before-mentioned experiments; they came from the same source and from the same parcel of trees.

Each tree has produced more or less fruit every year since 1899 to 1906 inclusive, and the average weight per tree for the whole of that period is:—

Three badly-pruned trees, 199.0 lb. of fruit per tree.

Three non-pruned trees, 183.6 lb. of fruit per tree.

Five well-pruned trees, 105.0 lb. of fruit per tree.

In order that readers may understand the size and market value—as well as the economic value

was sent to market earlier than it would have been, but I do not think that fact affects the issue. It is shown that the non-pruned and badly-pruned trees have—up to date—produced nearly double the quantity of fruit produced by the well-pruned; it is also shown that the latter have produced fruit nearly twice the value of the former, which makes them about equal in value (commercially) up to the end of 1906. The future will prove which system of management be the best of the three; but to predict future events by the past is not very difficult, and, judging by the progress made by the well-pruned trees since (and including) 1904, the result in the

Chionodoxa Luciliae, and it partakes of both of its parents in certain respects. It has erect flowers, thus partaking of one of the characters of *S. bifolia*, and with larger, broader, and more handsome segments than those of the *Scilla*. The reproductive organs resemble those of the *Chionodoxa*, and the colour is a pleasing pink, passing to nearly white. Its height approximates that of the *Chionodoxa*, but in the erect habit of its flowers it is superior to any of the pink varieties of *C. Luciliae*. One can only regret that its slowness of increase has as yet prevented its distribution. The beauty of this *Chionoscilla* should be a stimulus to the hybridiser of bulbous plants to produce others of equal beauty. *S. Arnott, Dumfries.*

The Week's Work.

PUBLIC PARKS AND GARDENS.

By W. W. PATTISON, Superintendent of the Parks and Open Spaces in the City of Cardiff.

Footpaths.—In public parks it is a matter of great importance to have the footpaths so constructed as to be at all times easy to walk upon, and clean during either wet or dry weather. In some respects walks in public grounds differ very considerably from those in private gardens or pleasure grounds. In the latter it is a common custom to have loose, clean gravel spread over the surface of the paths, which, when raked over, gives a trim and neat appearance to the walks and their surroundings. Loose gravel lying about the surface of a walk in a public park would never be tolerated, and it is one of the very first things visitors would complain about. The steel rake is a tool which is hardly, if ever, used upon public footpaths, its place being taken by the birch broom.

Material for use.—As a smooth, even surface is a necessity in a park walk, clean gravels of the pea and granite types are quite unsuitable, and have to give place to dirtier, but binding, gravels such as limestone or yellow Jersey. In this district, limestone gravel being the cheaper is invariably used in preference to the Jersey, although the latter is probably the better of the two. The great drawback of limestone footpaths is that during dry weather they get very dusty and soon kick up and become rough if pedestrian traffic is heavy. In showery weather, when only the top surface is moistened, or during a thaw after a period of frost, the upper layer becomes sticky and adheres to whatever comes in contact with it. This is not merely unpleasant for those who use the walks, but leads to excessive wear and tear. These facts show that although binding gravels meet some of the requirements essential for the construction of a smooth surfaced road, yet they are not by themselves the material with which to form an ideal park walk.

Asphalt is expensive.—In some of the smaller parks throughout the country, where the area covered by footpaths is not very great, the difficulty of having a clean, even, and good wearing road-surface has been overcome by substituting asphalt for gravel. Although one is keenly sensible of the fact that gravel paths seem to be far more in keeping with garden surroundings than asphalt paths, the convenience of the public must be the first consideration in such matters, and it is from the cost and not from sentimental reasons that asphalt has not been more generally used in parks. When it is remembered that different methods of asphaltting cost from 1s. 6d. to 3s. 6d. the square yard, it can readily be understood why this method of path-making has not become general in parks.

The dust nuisance.—The advent of the motor-car has made it imperative for those who are responsible for the maintenance of public highways to discover some cheap method of dealing with roads so as to reduce their wear and tear, and at the same time to minimise the dust nuisance. These objects are best attained by producing a hard, even, road-surface, which is the very condition needed for public footpaths, hence what meets the requirements of the former ought to be equally serviceable for the latter.

Coal-tar.—Up to the present time coal-tar has been found to be the cheapest and best material with which to treat dusty highways, and it is now being used in several parks in this neighbourhood in place of asphalt, and at about a quarter of the cost. It is all the better for being stale, and must only be used after boiling and while still hot. Tarring cannot be done excepting when the paths are perfectly dry and while the weather is fairly warm. The surface of the path about to be treated needs no picking up nor scoring, but simply requires the boiling tar to be sprinkled over it with a large flat brush similar to what is used for white-washing purposes. A layer of fine gravel about $\frac{1}{4}$ -inch thick is spread over the tar and rolled down, after which tar is again applied and another layer of finer gravel spread over it. The whole is once more rolled and tarred, after which the surface is dressed with gravel-dust which has passed through an $\frac{1}{4}$ -inch sieve, and the path is then ready for traffic.

Time of application.—The unfortunate thing about this work is that it has to be taken in hand during the season (from April till the end of September) when the greatest number of people visit the parks, so that every precaution has to be made to prevent the public from being inconvenienced to any considerable extent during the tarring operations.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower to Sir Trevor Lawrence, Bart., Burford, Surrey.

Deciduous species.—Such Orchids as species of *Catasetum*, *Cynoches*, and *Mormodes*, which rest during the winter months, must no longer be kept under the resting treatment. Where a large number of varieties of these species is grown it will be seen that some plants are more forward with their growths than others, and these should be taken in hand first. When the young shoots are about 2 or 3 inches high, shake the roots out of their old compost, cut away any that are dead, as well as any diseased pseudo-bulbs, and re-pot the plants in a mixture of fibrous loam, lumpy peat, and sphagnum-moss in equal parts, adding plenty of broken crocks. These plants, although requiring very large quantities of water when in full growth, should nevertheless have good drainage, so that the water may freely percolate through the soil. Ordinary flower pots, made about half full with crocks for drainage, and provided with copper wire handles about a foot in length, are suitable. The plants may then be suspended well up to the roof glass, this being very important, as a maximum of light during the growing and ripening period is essential to their welfare. After re-potting, suspend the plants on the light side of the hottest house, and afford water as advised in a former Calendar for the deciduous *Calanthes*. The following varieties deserve to be generally cultivated—some of them produce large handsome spikes of bloom which have a decorative value and delicious perfume:—*Catasetum splendens*, *C. macrocarpum*, *C. barbatum*, *C. tabulare*, *C. pileatum* (*Bungerothii*) and its several beautiful distinct forms, *Mormodes buccinator*, *M. Rolfei*, *M. colossus*, *M. pardinum*, *M. luxatum*, and *M. l. eburneum*, *Cynoches chlorochilum*, *C. versicolor*, *C. pentadactylon*, *C. peruvianum*, *C. Egertonianum*, &c.

***Lissochilus*, *Eulophia*, and *Cyrtopodium*.**—Immediately such species are seen to be developing their young growths, they should be re-potted in a mixture of fibrous loam, peat, crocks, and sand. The *Lissochilus* while growth is being made should be treated as an ordinary sub-tropical *Nymphaea*, standing the plants in about 4 inches deep of water until the end of the summer, when they should be taken out of the water and stood in a sunny position in the warmest house, but the roots must be kept thoroughly moist until after the plants bloom and the foliage commences to die, when it should be gradually discontinued. Place the *Eulophias* and *Cyrtopodiums* in a sunny position, and as near to the roof glass as possible. *Cyrtopodiums* should not be re-potted unless they absolutely need it, as they are more likely to bloom if kept in a pot-bound condition. The same remarks apply also to *Peristeria elata* (the Dove Orchid), and *P. Lindenii*; these plants are now starting to grow, and should be placed where they can obtain plenty of light, heat, and moisture.

FRUITS UNDER GLASS.

By ALEXANDER KIRK, Gardener to J. THOMSON PATON, Esq., Norwood, Alloa, Clackmannanshire.

Early vinerias, in which the Grapes have almost finished colouring, should be kept at a temperature of from 60° to 65° Fahr. at night-time, and it should not exceed 80° by day. A dry atmosphere should be maintained, and ventilation should be provided both by top and bottom ventilators, leaving the top apertures open a few inches all through the night. Test both the outside and the inside borders for dryness and supply sufficient water to keep the roots moist and the fruits plump; after watering apply a fresh mulching of moss litter to the border, and do not allow the soil to become excessively dry throughout the whole of the summer. Examine the rods for red spider, and use effective measures if this pest is detected. Tie in the sublaterals, and use all means to prevent the vines making secondary growths.

Vine "eyes" in 3-inch pots are now well rooted, and they require a shift into 6-inch or 8-inch pots. The compost should consist of turfy loam, with a little lime rubbish, wood ashes, and a sprinkling of phosphoric manure added, the whole to be mixed thoroughly. Pot firmly and stake and tie the growths. Pinch the laterals at their first leaves, and stop the leading shoot when it has made a growth of 4 feet. This will cause the buds in the leaf axils to become plump and to break stronger into growth the following season. Place the pots in a pit or in theinery where they will have a temperature of 65° at night-time and 85° by day.

Peaches and Nectarines, which have finished their stoning, can now be forced more freely, especially during favourable weather. The houses should be closed in the afternoon with a temperature of 80°, and the morning following the temperature will have dropped to 65°, which will be suitable. Syringe the trees at closing time and again in the morning. Guard against mildew and red spider, and if either pest makes its appearance place 1 oz. of soft soap and 1 lb. of flowers of sulphur in a pail of hot water, mix them thoroughly, and when cooled to 80° syringe the trees and repeat the syringing once daily. This mixture will destroy both the spider and the mildew. Attend to the thinning and the tying of the shoots, regulating them equally apart. Beware of over-cropping; if fruits of fine quality are desired, one fruit per square foot of space will not be too much to allow. Test the borders with the soil tester, and if found to be dry afford a good soaking of tepid manure water.

THE KITCHEN GARDEN.

By WILLIAM H. HONESS, Gardener to C. COMBE, Esq., Cobham Park, Surrey.

French Beans.—Seeds may now be sown in the open in a position where it will be possible to protect the plants in the event of late spring frosts. The ridges between Celery trenches are suitable for this sowing. The seeds are often inserted by means of a dibber, but this practice is not to be commended, because the plants in consequence are apt to come through the ground very irregularly. If even drills are drawn, and the seeds placed in these, they will all be covered with the same depth of soil, and the plants may then be expected to appear above ground at about the same time as each other. It being quite possible for plants from this sowing to get injured by frost, a further sowing should be made after an elapse of 10 days. Further sowings will be necessary to form successions according to the demand. If an occasional row of Butter Beans is added, they will help to add variety to the supply of vegetables, and this is a point worth consideration in most establishments.

Brussels Sprouts and Borecoles.—The forwardest plants of these have now served their purpose, and should be cleared off the ground forthwith. Their retention would give to the garden an untidy appearance, and the roots would extract much nourishment from the ground. The ground now to be cleared will be suitable for a crop of Celery, if provision for this crop has not been otherwise made.

Perpetual "Spinach" Beet.—This makes an excellent substitute for Spinach, and the plants yield an abundant supply through the winter months. They appear quite indifferent as to position, for they are capable of thriving under the shade of fruit trees, and in almost any out-of-the-way place in the garden.

Lettuce and Radishes.—Varieties of both the Cos and Cabbage Lettuce should now be planted in greater quantities in the open ground from sowings that were made in cold frames. Additional sowings should be made in the open. Seeds of the French Breakfast Radish should also be sown.

Potatoes.—Successional plantings of early and second early varieties should now be made.

Tillage.—Frequently loosen the surface of the ground between all growing crops such as Turnips, Carrots, Parsnips, Onions, &c., by the use of the hoe. It will greatly accelerate the growth of the plants.

Asparagus beds should be examined daily for the appearance of early growths, which should be carefully covered over with some light litter obtained from the alleys to afford protection from frost until the growths are long enough and numerous enough for cutting.

PLANTS UNDER GLASS.

By J. G. WESTON, Gardener to H. J. KING, Esq.,
Eastwell Park, Kent.

Celosia pyramidalis.—The earliest plants will now be developing their plumes; therefore, a selection should be made of the best, choosing those of a strong, sturdy habit, and discarding all those that exhibit weak, straggling growth, or "washy" and undecided colours. Re-pot the selected plants into 6-inch pots; using a compost consisting of two parts turfy loam, one part leaf-mould, and one part rotten manure, adding some sand during the process of mixing. Return the plants to a light position near the glass, giving each specimen plenty of room to develop its side shoots and acquire a perfectly pyramidal form. Syringe the plants night and morning, taking care to thoroughly wet the under-side of the leaves to dislodge red-spider, a pest to which *Celosias* are very susceptible. An atmospheric temperature of 60 to 65 degrees will suit the plants, admitting air early in the day, as the heat increases, but closing the house early in the afternoon, to conserve the sun heat. If large specimens are required, select the best plants when again ready for re-potting, putting them into 7 or 8-inch pots, in which size very fine plants may be cultivated. After the plumes are fully developed, cooler and drier atmospheric conditions will suit the plants better. They will then have reached the proper stage for use in decorating the conservatory or flowering-house, where they will be capable of lasting in beauty for several weeks.

Cockscombs.—These plants succeed under similar conditions to those advised for *Celosias*. Always keep the plants as close to the glass as possible, dwarfness being considered an essential characteristic of well-grown plants.

Euphorbia (Poinsettia) pulcherrima.—If plants of this winter-flowering species have not already been cut back to sound, well-ripened wood, let them be so treated at once, and placed afterwards in a warm house, where they should be syringed occasionally to induce them to break into growth. As soon as strong and healthy shoots, about 6 inches in length, are produced suitable for the making of cuttings, let sufficient be removed, with a "heel" to each, and inserted without any delay in "cutting" pots previously prepared in the propagating house. The cuttings should not be allowed to flag before they are inserted in the soil. They usually make roots in two or three weeks, after which air should be gradually admitted to the frame, in order to slightly harden the little plants before they are potted. Do not let them become pot-bound, as the fleshy roots are exceedingly brittle, and might thereby suffer damage.

Euphorbia fulgens (jacquiniiflora).—This species is rather more delicate than *E. pulcherrima*, in the sense that it cannot withstand rough treatment or a low temperature at any time. Propagation may be effected in the same way as in the case of that species. The roots being very fine, this plant succeeds best in comparatively small pots and a very porous compost. Excess in watering is most harmful at any stage.

THE FLOWER GARDEN.

By A. C. BARTLETT, Gardener to Mrs. FORD, Pencarrow,
Cornwall.

Hardy aquatics (continued from p. 235).—The recognised method of planting the hardy *Nymphæas* is to place the root-stocks in loosely-made baskets of soil, using thin pieces of turf on the top, and lacing the baskets across with willows so that the soil and plant may not float out. If the pond will provide sufficient nourishment, all that remains is to gently lower the basket into its place. In the case of an artificial bottom the basket containing the plant should be placed in a mound of soil, deep enough to just hide the rim of the basket. If the water can be maintained at a uniform level, the depth at which to plant will present no difficulties—the mounds can be raised for those varieties which succeed best nearer the surface of the water; but where the water line varies, careful consideration is required. The baskets must be sunk sufficiently deep to ensure that the crowns will not be exposed during the summer, and too great a depth during the winter must be guarded against, or it will be late before growth commences, and some kinds will either refuse to grow or flower only poorly if too far from the surface of the

water. As a general rule the *Marliacea* group will grow and flower well even at a depth of from 18 to 30 inches, while most of the *Leydekeri* section succeed best when about 9 inches from the surface of the water. After three or four years some of the more robust kinds—notably *N. Marliacea chromatella*—will require rigorous, annual thinning, or the flowers will be hidden by the luxuriant leaves. This thinning is best done by removing many of the side crowns, which, if required, can be used for increasing those varieties. *Aponogeton distachyon* does best in running water, and to enjoy the fragrance of its flowers it should be kept as near the edge as possible. The interest of the Lily pond will be increased if such plants as *Alisma Plantago*, *Butomus umbellatus*, *Richardia Africana* (*Calla æthiopica*), *Sagittaria*, and *Typhas* are planted near the edge, and in many cases a few of the floating plants (*Azolla filiculoides*, *Stratiotes aloides*, &c.) may be added.

Lobelia cardinalis.—Contrary to the general custom, we in Cornwall winter these plants out-of-doors, and find that under this treatment they keep much better than when coddled under glass. As soon as the flowering season is over, the stems are cut down to within 3 inches of the ground, the clumps are lifted entire and planted thickly on a south border, care being taken to plant firmly to prevent the frost from penetrating to the roots. If more than 6° or 7° of frost is anticipated, a thin layer of dried bracken, or some archangel mats, is placed over the crowns while the frosts last, and removed when milder conditions prevail. The crowns are now lifted, divided into clumps of convenient size, and planted in their flowering positions.

Wallflowers.—Seeds should now be sown thinly out-of-doors to provide plants for next year's spring bedding display.

THE HARDY FRUIT GARDEN.

By J. MAYNE, Gardener to the Hon. MARK ROLLE,
Bicton, East Devon.

Peach and Nectarine.—In the warmer parts of the country the removal of surplus shoots on these trees will have become necessary. Disbudding, as this practice is termed, requires much care and judgment, and the removal of surplus growths should extend over three or four weeks, allowing a week to intervene between each operation, for the removal of many shoots at one time would most likely cause a harmful check to the tree, and probably cause the majority of the fruits to fall off. The trees under notice fruit principally upon ripened wood of the previous year's growth. It is, therefore, necessary, that suitable shoots should be retained for that purpose, and in the case of established trees the shoot nearest the base of the present fruiting branch—and this on the upper side—should be the one reserved for next year's crop. In the majority of cases one shoot will be sufficient to retain, but if space exists for a second branch—and 1 foot at least should separate them—it may be permitted. In removing young growths having tiny fruits at their sides see that the latter are not disturbed; a shoot may be allowed to remain at intervals, and pinched; the few leaves will act as a protection to the young fruit. Pick off any curled or blistered leaves, for the blister disease quickly spreads during spells of cold, cutting winds.

Apricots.—Although these trees do not require the amount of disbudding that a healthy Peach or Nectarine does, there are always a number of shoots that must be dispensed with, whilst reserving the best placed so as to ensure a succession of bearing wood for another year. Gross shoots should be rubbed off, retaining only those nearest the wall on the upper side, as well as those on the lower side, to form spurs, pinching these at the third or fourth leaf. Naturally-formed spurs—that is, those shoots that do not grow beyond a couple of inches—need no stopping, but are better for thinning when too thickly placed. Clusters of fruits should be thinned, rubbing off the smaller ones and any that may be placed in unfavourable positions. Young trees making robust growth should be pinched; extra strong growths are of little value as fruiting wood, and if they are allowed to develop at will they quickly spoil the shape of the tree. The above remarks also apply to other stone fruits, including the Cherry and Plum.

THE APIARY.

By CHLORIS.

Time for Careful Examination.

Feeding.—The busy season is now approaching, and every hive should be examined, and its exact condition as to food, brood, and whether the occupants are suffering from dysentery, ascertained. The bees now require a great deal of food, as the brood is, or should be, rapidly increasing. Money spent on feeding now will be well laid out, for food will strengthen the colonies and render the bees ready for gathering the main honey crop, the season of which varies according to the district and the flower from which it is principally gathered. A suitable food is made as follows:—White sugar, 1 lb.; water, 7 pints; salt, 1 ounce; vinegar, 1 tablespoonful. Some beekeepers add naphthol beta, salicylic acid, or phenol solution as a preventive of foul brood, but, as the value of these substances is questionable, it may be omitted. However, should they be desired, use as follows:—Dissolve a small package of naphthol beta in 2 ounces of alcohol or methylated spirit, and mix it with about 28 lbs. of the syrup. Salicylic acid, 1 oz. in 2 pints of water, will be sufficient for mixing with 8 quarts of food, while $\frac{1}{4}$ oz. of phenol added to each quart of syrup when cool will suffice.

The best time to supply the food to the hives is whilst the bees are not on the wing, and the jar should be placed over the feed hole, and be wrapped in some non-conducting material, so as to conserve the heat of the liquid. (See fig. 108.)

FIG. 108.—FEEDING BEES.

A, top of brood-chamber; B, quilt; C, feed-hole; D, the flap cut on three sides; E, wood $\frac{1}{2}$ in. to raise bottle; F, hole; G, bottle of syrup.

Water.—If no pond or stream exists near the apiary a number of receptacles containing water should be placed in the garden or field, and to prevent the bees from being drowned a number of stones should be placed in the jars. Bees require large quantities of water whilst raising brood, and they may often be seen on the mud on the sides of a pond in search of water.

Brood.—To induce a rapid production of brood place the bottle of syrup over a different frame about every ninth day. Where the bees have sufficient honey for food, the cappings of one frame should be bruised each ninth day, and the comb be placed in the centre of the frames containing brood.

The wax moth.—In hives that have not been cleansed of dead bees and accumulated rubbish the wax moth finds an excellent place in which to lay her eggs. Weak colonies will suffer more from this pest than the stronger ones. The grubs of the wax moth are to be found chiefly in the sawcut on the top of the frame and in cocoons in the quilts.

Warm quilts.—Very few persons seem to realise how necessary warmth is to successful beekeeping. It is well to reduce the size of the brood chamber by the aid of dummies, and to keep the quilts well tucked into the corners and about the feeders, and much heat may be conserved by placing a sheet of brown paper between the quilts, as paper is a bad conductor of heat.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Special Notice to Correspondents.—The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.

Illustrations.—The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but he cannot be responsible for loss or injury.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY, APRIL 20—
German Gardeners' Society meet.

TUESDAY, APRIL 23—
Midland Daffodil Soc. Exh., Birmingham Botanic Gardens (2 days).

WEDNESDAY, APRIL 24—
Roy. Bot. Soc. Exh.
Darlington Hort. Soc. Spring Fl. Sh

FRIDAY, APRIL 26—
Royal Botanic Soc. meet.

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich—48°4'.

ACTUAL TEMPERATURES:—
LONDON.—Wednesday, April 17 (6 P.M.): Max. 57°; Min. 40°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—Thursday, April 18 (10 A.M.): Bar., 29°9'; Temp., 45°; Weather—Overcast.

PROVINCES.—Wednesday, April 17 (6 P.M.): Max. 49° S.W. Ireland; Min. 40°, Scotland, N.

SALES FOR THE ENSUING WEEK.

TUESDAY AND WEDNESDAY—
Duplicate Plants from the Westfield Collection of Orchids, by order of Francis Wellesley, at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 1.

THURSDAY—
Hardy Border Plants and Bulbs, Lilliums, Azaleas, Palms, and Plants, at 12, 1,500 Roses, at 1.30, at 67 and 68, Cheapside, E.C., by Protheroe & Morris.

FRIDAY—
Choice imported and established Orchids from various sources, at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.45.

Report of Conference on Genetics. "Genetics" is a term devised by Mr. Bateson to include the sum total of the phenomena of heredity, variation and cross-breeding in all their several degrees.

It applies to the breeding of animals and of plants in the same manner. So far as we know, the term was first used by Mr. Bateson in his Presidential Address at the Hybridisation Conference in July last. Its convenience will ensure its general adoption and the "Report of the Third International Conference" just issued by the R.H.S. will greatly facilitate its diffusion. As to the report itself, we may at once say that no more valuable document has ever been issued by the Society, nor one more full of promise for the future. As the title page tells us, it is devoted to subjects connected with "the hybridisation (the cross-breeding of genera or species), the cross-breeding of varieties and general plant breeding." It is edited by the Rev. W. Wilks, the Secretary of the Society, and not only is no one likely to "judge harshly" of his efforts, but most

assuredly those who know anything at all of the labour involved in passing such very highly technical and scientific matter through the Press will be the first to congratulate the Editor on the success of his efforts. The very potent aid of Mr. Bateson is fittingly acknowledged, and recognition is also made of the "vast indebtedness" of the Editor to Mr. Hutchinson, "the Society's librarian." Incidentally, we may allude with satisfaction to this recognition of Mr. Hutchinson as the Society's librarian, as it secures the fulfilment of the requirements of the trust deed under which the library is held.

Turning to the contents of the volume, we find the foremost place, after the prefatory note, allotted to a portrait of Abbot Mendel; a second and a third portrait of the ecclesiastic whose experiments have, after the lapse of several years, been turned to such excellent account, are given eighty pages further on, accompanied by a biographical notice from the pen of the Editor, as well as by an exposition of the facts and phenomena and the deductions from them which go to make up what we now call "Mendelism." Those who only require to obtain a general notion of what Mendel did, and how he did it, will read this brief summary with much interest. Those whose object it is to pursue the intricacies of the subject will read the subsequent pages with avidity, for nowhere else can they find in such convenient form a statement of the developments that have taken place since Mendel's publication was unearthed. Many who previously have had but a confused idea of the subject will find here as clear an exposition as is possible to be obtained from a printed page. Those who were fortunate enough to see the results as exhibited at the conference, and the record of which is given in full, will, of course, be the better able to grasp their significance. There remain those who have been actively engaged in the practical experiments, so many of which are recorded in the pages of the report. The opinion of the members of this latter class must, of course, be treated as "dominant." The opinions of others must be treated as "recessive." There is the more reason for this, for, up to this time, we believe that all the experimenters are in substantial agreement as to the general truth of Mendelism. There are difficulties and complexities, no doubt, which at present are not explained, and there are some facts which do not seem to tally with Mendelian principles. Nevertheless, making allowances for these doubts and difficulties, there is, as we have said, substantial agreement among all those who have undertaken experiments, under like conditions, for they have come to the same general conclusions.

The social amenities by means of which the severities of the congress were lightened, and an opportunity given to show hospitality to our foreign guests, are all fully set forth in the report, but, as they were all published in the Press at the time (barring the bills of fare!) it is not necessary to refer to them again. Of much more permanent value is the list of exhibits arranged in the great hall for the purpose of illustrating Mendelian phenomena. These may be referred to again and again with advantage. They illustrate the experiments made by Miss Saunders at Cambridge, the repetition of Mendel's experi-

ments on Peas by Mr. Lock, the results obtained with Wheats and other cereals by Mr. Biffen which are of extreme value not only from a scientific standpoint, but also from their direct practical importance. A similar remark applies to the experiments and observations with Potatoes, sheep, ducks, rabbits, pigeons, horses, fowls and other subjects.

Under the heading "Conference" will be found Mr. Bateson's introductory address, which was printed in full in our columns at the time. Then follow the papers and memoirs contributed by various members, with notes on the discussion which took place. On most of these a report also was given in our pages, whilst others of a highly technical character, and some appealing to mathematicians rather than to physiologists, will be found in the report before us. The papers of M. Camus and Mr. Lynch on spontaneous hybrids will be very serviceable for reference. It is to be regretted that the complete catalogue drawn up by M. Camus could not be given owing to its length, but it is earnestly to be desired that some other means may be found of giving to the world so useful a document.

As was well said at the conference, science must come first, its application afterwards, otherwise we shall be doomed to go on in the old routine, rule-of-thumb methods—good enough in their way, but not making for progressive improvement and new developments. Nevertheless, those who, as they say, want facts rather than theories, will find them here in profusion, but we venture to say that this class of cultivator will not be able to avail himself of those facts or compass his objects so rapidly as he who, by the aid of theory, learns how to apply the fact to useful purposes. The experimenters are the men who bring the ore to the surface; the theorists are those who smelt it and render it available for use; the cultivator is the man who has intelligence and tact enough to employ it for his purposes. "Technical" though some of these papers may be, it is impossible not to recognise their enormous importance from a practical point of view. Take, for instance, such communications as that of Sir Daniel Morris on the "Improvement of the Sugar Cane by Hybridisation," the remarkable memoirs on the "Breeding of Cereals" by Prof. Zavitz, M. Philippe de Vilmorin, Mr. Biffen, and Prof. E. S. Salmon. The importance of these communications as pointing out the way in which improved varieties, suitable for different conditions or varied purposes, may be obtained, as well as of varieties capable of resisting disease, can hardly be over-estimated. Other memoirs will appeal more especially to the florist, such as that on Carnation breeding in America. Expressed in money terms this means in the United States alone an annual money value of a million pounds, and a capital value of five million pounds sterling. These are figures for the practical man to ponder over. Mr. Arthur Paul's note on the derivation of some of our newer Roses will attract the attention of Rosarians, whether they be amateurs or those commercially interested. From the point of view of the application of Mendelian principles to the practical work of the hybridiser, Mr. W. Laxton's paper on the cross-breeding of Peas

PEONIES AS CULTIVATED IN THE NURSERY OF THE YOKOHAMA NURSERY COMPANY, YOKOHAMA, JAPAN.

and of hardy fruits is highly important. He evidently recognises the value of Mendelian experiments, and shows how and why they may fail in particular instances, and how much patience is required by the experimenter. Taking a combination of characters as requisite in a fruit to render it commercially valuable, he points out that, by chance, the experimenter may be lucky enough to combine in one fruit all the desired qualities, but that if, on the contrary, one be deficient, the result is failure. "Therefore, as we have not any guide as to these characters being either dominant or recessive in their generation, we have to make very many crosses before we succeed in combining them all in one plant." Mr. Laxton goes on to say that he has never been able to reproduce any one of his seedlings in all of its characters even by effecting the same cross, and in illustration he cites the case of the Strawberry Royal Sovereign, which was raised by crossing Noble with King of the Earlies. The same cross has been repeated many times, but no Royal Sovereign has been produced. In like manner Gradus Pea was raised out of Earliest of All by pollen of Duke of Albany. The same cross has been made many times, but no Pea exactly like Gradus has been found among the offspring.

The fact that the results obtained in crossing are not always in conformity with the Mendelian law is attributed by Mr. Laxton to the circumstance that he has used "impure" and not fixed strains, that is, seedlings of the second and third generations that are not fixed types. It is, however, among such seedlings that the greatest "breaks" are to be expected in the future. The volume closes with a paper on the phylogeny of Orchids, which has a melancholy interest, inasmuch as it was prepared by Prof. Pfitzer, of Heidelberg (not Stuttgart as printed) for insertion in the report. The professor died before he could effect his purpose. The paper was found on his writing-table and forwarded by the executors to the secretary. Few that saw Prof. Pfitzer and admired his talent and geniality could have expected that his career was to be so soon terminated.

A full index closes a volume which is most creditable to the society and to all concerned in its production. For many years to come it must serve as a most valuable book of reference and a most potent stimulus to the promotion of the science of genetics and to its practical application.

OUR SUPPLEMENTARY ILLUSTRATION to the present issue is reproduced from a photograph kindly supplied by Mr. A. DIMMOCK, and illustrates a field of Pæonies as cultivated in the nursery of the Yokohama Nursery Company, Yokohama, Japan. Most of the plants represented in the picture are varieties of *Pæonia officinalis*, and are therefore of the type known as herbaceous, which, generally speaking, are easier of cultivation in this country than those of the shrubby type, such as varieties of *P. Moutan*. The Yokohama Nursery Company, however, cultivates both sections in large numbers, and of those which are annually exported from Japan, a considerable quantity is sent to Britain. Some of our readers had the opportunity of seeing an excellent group of tree Pæonies in pots, shown by W. JAMES, Esq.,

West Dean Park, Chichester, at a recent meeting of the Royal Horticultural Society. Those plants, which were awarded a medal and a cultural commendation, were obtained direct from Japan, and we have been favoured by the following particulars of them sent us by Mr. W. H. SMITH, gardener at West Dean. Mr. SMITH writes as follows:—"We had a quantity imported from the Yokohama Nurseries during the time of the war between Russia and Japan. When the plants arrived, they were laid in rough leafmould until their roots had commenced to make small fibres, when they were potted up into 8-inch pots. The compost was one of rough, fibrous turf, leafmould, and rotted cow manure. After potting, the plants were placed in a cool orchard house, and they were watered sparingly for some time. When they had filled the pots with roots, they were afforded weak liquid manure until the flowers commenced to show colour, but no longer. When the flowers faded, the plants were placed outside under the shade of a north wall until the leaves were hardened, when they were put in the full sun to ripen the wood. After the flowers were cut, manure water was again afforded each time the plants were watered. The Pæony appears to be a gross feeder. Two hundred Pæonies were imported, and we only lost two plants." The plants as exhibited were handsome subjects for the decoration of the conservatory and dwelling-house. The flowers are no less attractive in form than they are bright in colouring, and the foliage itself is of good effect. See also a letter on p. 257.

LINNÆUS.—The 200th anniversary of the birth of LINNÆUS is to be celebrated at Upsal on May 28 and 29. The university has issued invitations to various societies to send representatives, and Mr. B. DAYDON JACKSON has very appropriately been selected to represent the Linnæan Society of London. The society, as is well known, is in possession of the herbarium, library and many manuscripts of the great Swede.

THE LONDON GEOLOGICAL FIELD CLASS has arranged its excursions for the study of the London district, under the direction of Professor SEELEY, to commence on Saturday, April 27. Mr. J. W. JARVIS, St. Mark's College, Chelsea, is the hon. secretary.

THE SURVEYORS' INSTITUTION.—The next ordinary general meeting will be held on Monday, April 22, at 4 p.m., being the second of the two afternoon meetings arranged for the convenience of the country members, when the discussion on the paper read by Mr. LESLIE S. WOOD on December 10 last, entitled "The Improvement of our Woodlands," will be resumed.

PIGMY TREES.—Pigmy trees are of such interest that it would seem worth while for some nurseryman to secure and propagate the pigmy form of the Black Jack Oak, *Quercus nigra*, which botanists tell us exists in the woods near Millville, N.J. The usual height of the Oak is 30 to 40 feet, but the pigmy ones referred to have been observed of no more than from 2 to 6 feet, the very dwarfest of them bearing acorns. The *Quercus nigra* is a beautiful tree at all times, especially in summer when clothed with its large shining green leaves. A note in the *Botanical Gazette* describes a forest of dwarf trees found upon the west coast of Vancouver Island, British Columbia. The little trees are of three kinds, *Thuja gigantea*, *Tsuga Mertensiana* and *Picea sitchensis*, and range in height from less than 1 foot up to 2 feet or a little more. No doubt soil and situation have had to do with the dwarfing of these trees, still the character would be so fixed that even in favourable situations for growth great variation from old forms would not be looked for for some time. *The Florists' Exchange*.

SOUTH-EASTERN AGRICULTURAL COLLEGE.

—A meeting of the Governors of the South-Eastern Agricultural College, Wye, Kent, was held on the 15th inst., the Right Hon. Lord ASHCORBE presiding. The Principal reported that 110 students would be in residence for the summer term, commencing April 22. The following appointments were made: Mr. C. H. HOOPER, F.S.I., Librarian; Mr. C. GIMINGHAM, Analytical Assistant; Mr. B. N. WALE, B.Sc., Assistant Agricultural Zoologist. The Egyptian Government has conferred the Order of Osmanie on Mr. THEOBALD, the Vice-Principal and Entomologist. Prize day was fixed for July 24, when the Right Hon. AILWYN FELLOWES will present the awards. The Grocers' Company have made a donation of 10 guineas to the College. The British Dairy Farmers' Association will visit the College on June 12. *M. J. R. Dunstan, Principal.*

THE INTERNATIONAL HORTICULTURAL EXHIBITION at Dresden promises to be both comprehensive and interesting. The special show of Orchids is to be held from May 4 to 6, and that of other plants from May 8 to 12. The jury meets on Friday, May 8, and for the general section on Thursday, May 9. The grand opening of the Exhibition by His Majesty THE KING OF SAXONY is fixed for Saturday, May 4, at 11 a.m. On Sunday, May 5, meetings will be held of the German Horticultural Societies. A banquet will be given on Monday in honour of the judges, members of the Press and other guests, and invitations have been issued for a performance at the Royal Opera House, on Tuesday, May 7. Wednesday, May 8, is to be devoted to a day excursion into Saxon Switzerland, comprising a steamboat trip to Wehlen, thence through the Uttowalder Grund to The Bastei and descending to Rathen, and so back to Dresden.

MANNHEIM INTERNATIONAL EXHIBITION.

The programme for the horticultural shows at the great Jubilee Exhibition, to be held from May to October in this Rhenish city, has reached us, through the courtesy of Mr. OTTO BEYRODT, Marienfeld, Berlin, who will supply intending exhibitors with information about exhibits of Orchids and novelties at these shows. A grand hall is to be placed at the disposal of the exhibitors, and everything will be done to make the exhibition a great success. Several English amateurs are to act as members of the jury, and the council hope to welcome several exhibitors from this country. All the schedules are ready, with the exception, apparently, of that for the exhibition of Orchids to be held from October 18 to 20. The following are the dates of the various displays:—Orchids and novelties in plants and flowers, May 7 to 9; forced fruits and vegetables, May 18 to 20; Cactuses and other succulents, June 6 to 19; Strawberries, early Cherries and early vegetables, June 8 to 11; cut Roses, June 22 to 24; early fruits and early vegetables, July 13 to 15; Ferns: tropical, subtropical, useful and industrial plants of all kinds, August 2 to 6; early kernel and stone fruits, August 10 to 12; cut Roses and vegetables, September 21 to 24; fruits, October 5 to 14; Orchids, October 18 to 20.

THE STUDIO YEAR-BOOK OF DECORATIVE ART.—This is well described as being a guide to the artistic construction, decoration and furnishing of the house. Whether all the original and adapted designs are equally beautiful and appropriate, we will not decide, though we take special interest in the representations of garden furniture, trellises and flower stands. The whole makes a large volume, well got up and containing so much in the way of letterpress and pictures that each reader must find something herein to please him. The year-book is published at the offices of the Studio; London, Paris, and New York.

THE ACTION OF CHLOROPHYLL IN RELATION TO LIGHT AND TEMPERATURE.—M. LUBIMENKO, in a paper in the *Comptes Rendus*, shows that:—1. Under the conditions in which the chemical reactions in the interior of a living plant take place, light and heat usually act in the same way as regards the decomposition of carbonic acid gas. 2. There is, for heat as for light, a most effective or "optimum" degree of intensity beyond which the amount of assimilation is diminished. 3. The diminution of the assimilating power beyond this optimum intensity is much more strongly pronounced in shade-loving than in light-loving plants.

HARDY PALMS.—There has been some confusion with regard to the name of the Palm commonly known as *Chamærops Fortunei*. Signor BACCARI now refers this Palm to the genus *Trachycarpus*, and considers it to be synonymous with *T. excelsa*. In *Trachycarpus* the endosperm, or white tissue constituting the bulk of the seed, is homogenous, whilst in *Chamærops* it is "ruminate" and presents a mottled appearance.

MEEHAN'S MALLOW MARVELS.—In MEEHAN'S nurseries, Germantown, Philadelphia, experiments have been going on for some years on the production of this *Hibiscus* in various colours other than its natural one, which is a rose colour, the chief object being to obtain a hardy crimson-flowered one by hybridizing it with the crimson one from a tropical clime. This idea of thus improving this flower was first suggested by the late THOMAS MEEHAN, and his suggestion interested one of his employees, ERNEST HEMMING, and to him is due the credit for obtaining the beautiful hybrids which have resulted from the crossing. It has been a task of several years to reach the results at the present day. Year after year, when the beds of plants are in flower, they attract great attention. There are all colours from pink to crimson; but all the time but a very few of the best were saved, with which to continue further crossing. At the present time four sorts have been selected as eminently worthy of dissemination; they have been named Crimson Marvel, White Marvel, Red Marvel and Pink Marvel. Although the *Hibiscus moscheutos* is one of the parents, the sorts selected do not have the same style of growth. There is not a rank, coarse, open growth, but rather a taller, more branching habit, of much more pleasing appearance than that of *H. moscheutos*; and although a height of from 6 to 9 feet is made in good soil, the growth is always well able to take care of itself in storms. The extreme hardness of these Mallows cannot be too clearly emphasized. They are absolutely hardy wherever *H. moscheutos* is hardy, and this is equivalent to saying practically all over the Northern States. These Mallows, like their parents, are tenacious of life. In spring, after severe winters, some of the seedlings have been thrown to the top of the ground by frost, yet have not failed to grow when reset; and in this respect they surprise those not aware that the *Hibiscuses* are known to transplant well. *Hibiscus* plants start into growth very late always, often not before the close of April. The best situation for *Hibiscus* is an open sunny one, where the ground is deep and moist. Planted in such a place there will be a display of their large handsome flowers—some of them 7 to 8 inches in diameter—through August and September. *The Florists' Exchange*.

NURSERYMAN'S "DIAMOND WEDDING."—On Friday, April 5, Mr. and Mrs. CRICK, of Houghton Park Nurseries, Ampthill, Beds., celebrated their diamond wedding. Mr. and Mrs. CRICK have lived at Houghton Park Nurseries nearly the whole time since they were married, for Mr. CRICK succeeded his father in the business 75 years ago, and still takes an active part in all that pertains to the management of the nurseries.

CALCEOLARIAS.—How many of us, we wonder, know how many species of *Calceolaria* there are? Not more than half a dozen of them, we suppose, are in cultivation, disregarding, of course, the innumerable varieties raised by the florist. Dr. KRANZLIN, known to Orchid growers for his researches in the great family of the Orchidaceæ, has now turned his attention to the *Calceolarias*, and in a recent number of *Das Pflanzenreich* has described and systematically arranged about 200 species, besides some of uncertain nature and various hybrids, 15 of which latter, including *C. Burbidgei* ×, are described. Numerous illustrations are provided as well as a full index.

GRAFTED DAHLIAS.—M. LOMBARTRIX describes, in a recent number of the *Jardin* a *Dahlia* growing in a pot and producing, from August to October, nine different varieties from one plant. The stock was a tuber of the variety known as *Etoile du diable* (!) On this were grafted in spring scions of *Primrose Dame*, pale yellow; *Octopus*, pale lilac; *Domini*, white with fawn-coloured edges; *Starach* (?), orange scarlet; *Emperor*, plum-coloured; shaded with yellow; *Cinderella*, bright amaranth; *Major Haskins*, crimson; *Perle de la Tête d'Or*, pure white; and *William Cuthbertson*, reddish apricot. Grafting is done in various ways, no one method having apparently any special advantage over the others, the grafted plant being kept shaded under a bell glass till union is effected, in about three weeks. M. LOMBARTRIX has also succeeded in grafting *Dahlias* in the open ground, in August, keeping the grafts shaded.

WEEDS AND SUSPECTED POISONOUS PLANTS OF QUEENSLAND.—Mr. F. MANSON BAILEY has drawn up this useful copiously illustrated book dealing with noxious plants, especially in Queensland. The author is too good a botanist to acknowledge any plants to be "weeds" except those which make themselves objectionable in cultivated ground. Clearly what is a weed in one place is not in another. It is hard to think of *Nymphæa flava* as a weed, but Mr. BAILEY tells us it is one of the worst water-weeds in Queensland; neither should we here look on the *Tomato Lycopersicum esculentum* as a plant to be despised but, rather, developed.

LILAC CULTURE IN GERMANY.—The raising of Lilac plants for forcing from autumn till late spring has not "caught on" in England as has been the case for 20 years in Germany, and we mostly draw our supplies, as did the Germans formerly, from France. I much doubt if the latter do so to any great extent, at the present day, partly for patriotic reasons, and partly because it has been found that as good material can be grown in their own country as in France, whilst money is kept at home and employment found for the labouring classes. One of the largest growers, if not the very largest, is Herr F. SINAI, of Frankfurt-on-the-Main, who has 150 *morgen* of land, three-fourths of which is under Lilac. In 1891 he had 20 *morgen* of land devoted to this crop. His chief Lilac for forcing (he sells but few plants) consists of seedlings, selecting these by reason of such peculiarities of growth as promise by further cultivation to show valuable features: a method that has resulted in a number of seedlings being raised widely superior to well-esteemed varieties. Besides the seedling which he raises annually, there are the best of the trade varieties, as Charles X., Marie Legraye, Andenken an L. Späth, Michel, Buchner, Mme. Lemoine, &c., which are grown for forcing purposes, and a number of the Marly Lilacs, which in less than four years in the nursery set a good number of flower-buds. These Lilacs are grown from suckers not budded or grafted, and they flower well in balls, and thus save the expensive potting work. Herr SINAI forces 108,000 Lilac plants in all, but the demand is not great before Christmas. The plants for that season are placed in the forcing houses on November 27, and these consist entirely of unprepared plants. F. M.

THE RELATION OF METEOROLOGY TO HORTICULTURE.—A second lecture on the above subject was given by Mr. R. H. CURTIS, F.R.Met.Soc. at the Royal Horticultural Society's meeting on the 16th inst. He dealt on this occasion with rainfall, and said that water in the form of steam or invisible vapour, an important constituent of the atmosphere, always present, although to an extent which varies greatly in different regions, and is also constantly changing at the same place. He explained briefly that the maximum amount of this invisible vapour which the air can contain depends upon the temperature of the air, and that, for example, whilst at a temperature of 60° it could hold in the gaseous form about six grains of vapour in a cubic foot of air, that amount would be reduced by one half if the temperature of the air were to be lowered to 40°. Whenever, therefore, the amount of vapour exceeds the maximum which the air can hold, the excess, becomes at once condensed into water, the particles of steam uniting to form exceedingly minute drops of water, far too minute to be distinguished individually, but forming in the aggregate a more or less dense cloud or fog. It was pointed out that in this operation dust played a very important part, and formed nuclei upon which the minute water drops were formed; but in every case cooling of the air was the primary cause of the condensation. The way in which the necessary cooling was brought about was then explained, and it was shown that, so far as the formation of rain-clouds was concerned, by far the most common cause was the dynamical cooling due to the expansion of the air. The part played by hills and mountain ranges in lifting currents of air to higher levels, where they expanded owing to the reduced pressure to which they were subject, was then explained, and it was shown that the excessive rainfall of certain hilly regions was due to this cause. The action of the sun in causing ascending currents of air was shown to be another cause of expansion and the formation of cloud. The way in which cloud particles combined to form rain drops was then explained, and the lecturer passed on to the subject of the measurement of rain and to its geographical distribution, and especially its distribution over the British Islands. In this connection he referred to the British Rainfall organisation now under the direction of Dr. H. R. MILL, which collates and discusses the observations of some 4,000 observers of rainfall, and puts the results into a form in which they become serviceable to the public. Reference was made to the influence of rain upon vegetation, and some views were exhibited in illustration of this part of the subject, but it was pointed out that the work of the meteorologist was to obtain and put into a useful form the elements of climate rather than to show how they were made use of in the economy of plant life. Attention was directed, however, to the connection which Dr. W. A. SHAW, F.R.S., the Director of the Meteorological Office, had noticed between the amount of the rainfall in the autumn and the yield of wheat in the succeeding harvest. This had led to the discovery of a remarkable periodicity in the yield of wheat, which had enabled Dr. SHAW to prepare a formula by which the probable yield of wheat for a given district can be calculated, and a diagram was exhibited showing the amounts so calculated and the actual yields for the Eastern Midlands for a long series of years, attention being called to the remarkably close agreement shown between them. The relative frequency of rain at different hours of the day and the relative amounts which fall were then referred to. It was shown that about 5 or 6 a.m. was the period at which rain fell most frequently, and that at midday it was least frequent. The amount of rain was also generally greatest in the early morning, but at Kew more rain fell in the afternoon than at any other period; in other words, whilst an umbrella would be most often needed in the early morning, it would be most urgently required in the afternoon. After referring to the storage of rain water for horticultural purposes, reference was made to floods, and the lecture was concluded with a series of views taken in the Thames Valley during the great flood of November, 1894.

A GARDENER'S REMARKABLE LENGTH OF SERVICE.—The funeral of Mr. THOMAS FREEMANTLE took place in the Romsey Cemetery on Saturday. Mr. FREEMANTLE, who had reached the age of eighty-one, had worked in the gardens at Broadlands for seventy-five years, having entered the service of Lord PALMERSTON at the age of six, and afterwards he continued in the service of Lord MOUNT TEMPLE and then in that of the Right Hon. EVELYN ASHLEY. Mr. ASHLEY showed his deep respect for his old servant by being present at the funeral. Among the gardeners present was Mr. CORNELIUS MEDLEY, aged eighty-eight and still at work, at his own wish. He has been employed in the same gardens for seventy-six years.

GARDENER APPOINTED A SCHOOL MANAGER.—At the annual general meeting of the subscribers to the Esher National Schools, Mr. E. BURRELL, of Claremont Gardens, was chosen as one of three foundation-managers for the ensuing three years.

Publications Received.—*Nature's Own Gardens*, written and illustrated in colour and line by Maud W. Clarke: Dent & Co.

LAW NOTES.

WORKMEN'S COMPENSATION POLICIES.

So much has already appeared in the daily papers on the subject of the Workmen's Compensation Act, 1906, that it is scarcely necessary to deal in detail with the provisions of this Act which will come into force on July 1 next. At the same time, the fact that so much matter has already appeared in print has apparently tended somewhat to confuse the general reader, and it may therefore be useful first to clear the air a little, and, secondly, to consider the all-important point of the form of policy which is likely to give due protection to an employer.

CASUAL EMPLOYMENT.

In the first place it should be borne in mind that householders and others, in their *private* capacity, are liable for injuries to all classes of workpeople employed by them, whether in the capacity of clerks, foremen, servants, &c., unless their earnings exceed £250 per annum, or unless they are only "casually" employed. (On the other hand, where a person employs a workman for the purposes of the employer's trade or business, he is liable to compensate the workman for injuries sustained, whether he is at the time only "casually" employed or not.) The Act does not state what is to be deemed "casual employment," and many interesting questions have already been discussed in the public journals on this subject, whether, for instance, a jobbing gardener or a person who comes to mow the lawn or to clean windows, either intermittently or at due intervals, can be deemed to be "casually" employed. No authoritative statement can possibly be made until questions of this kind have come up in the law courts for decision by the judges, and, by means of insurance, all employers will presumably be wise enough to leave litigation on the subject to be fought out by the company with whom their insurance is effected. What the public have to do is to see that they are protected in the case of injuries to workpeople of all kinds; if any case should afterwards be found to come within the Workmen's Compensation Act, 1906. The proper method of meeting the difficulty is to arrange with the insurance company to undertake all possible liability. Most of the companies are prepared to do this, provided the insurer pays an additional 25 per cent. to cover persons occasionally (though in strictness, perhaps, not "casually") employed, over and above the premium paid for the insurance of those persons who are in the insurer's regular employment. For instance, supposing a householder has four servants, the average charge of the insurance company will be 3s. (in some cases 2s. 6d.) per head, that is to say, 12s. in all. For an additional 3s. (that is to say, 25 per cent. added on to this premium) the insurance company undertakes to protect the insurer against accidents to

persons who, though not employed permanently, may be deemed to be something more than "casual" workmen. It should be borne in mind that workpeople under the age of 21 years are entitled to compensation with this additional advantage, that they are entitled to full wages instead of half wages) where the earnings of the minor in question do not exceed 10s. per week.

SUB-CONTRACTING.

As already explained, persons who employ workpeople for the purpose of their trade or business are liable to pay compensation, whether the workman is wholly or only "casually" employed at the time of the accident; but in connection with trade matters there is a further liability on the employer. The Act provides that where the trader (called the principal) contracts with another person (called the contractor) for the execution by or under the contractor of the whole or any part of any work undertaken by the principal, then the principal is liable to compensate the contractor's workman for injuries sustained in the execution of the work just as much as if the workman were employed direct by the principal himself. Suppose, for instance, that a firm of nurserymen, whom we may refer to as A. & Co., were to enter into a contract for laying out the grounds of an estate in the north of England. Instead of A. & Co. going up to carry out the work themselves, they might write to B. & Co., a firm in the north, and arrange for them to carry out the work at trade-prices on their behalf. If one of B. & Co.'s workmen is injured while the work is being carried out A. & Co. are liable to compensate him. It is true that A. & Co. are entitled to recover from B. & Co. any compensation which they may have to pay. But suppose B. & Co. should be a small firm without much capital, and suppose that the heavy claim resulting from the injury to their workman were to prove the last straw and land them in the Bankruptcy Court? In that case A. & Co. might find themselves unable to recover anything more than a small dividend from B. & Co.'s estate, but A. & Co. would still have to go on paying the compensation, or annuity as the case might be, to B. & Co.'s injured workman. Here, therefore, is a case where traders must be careful to protect themselves under their insurance policies.

FORM OF POLICY.

The following is a sample of the policy which some of the insurance companies are offering to insurers at the present time:—

THE X.Y.Z. ACCIDENT CORPORATION.

A.B. of &c. (hereinafter called "the Employer") having paid to the above Corporation the sum of £ : : on account of premium for the Indemnity hereinafter mentioned, it is hereby agreed as follows:—

The Corporation indemnifies the Employer fully and completely against his or her entire liability however protracted under or by virtue of The Workmen's Compensation Act, 1906, The Employers' Liability Act, 1880, Lord Campbell's Act, 1846, The Common Law, The Workmen's Compensation Acts, 1897 and 1900, in respect of any injury, fatal or non-fatal, which, at the time or times during the continuance of this Policy, shall happen to any servant whilst in his or her employ, and performing work for him or her.

The Employer by the acceptance of this Policy agrees—
To give notice to the Corporation at its Head or Branch Office of any claim, either verbal or in writing, made upon him.

To render the Corporation all reasonable assistance in connection with any accident, or any claim which may arise under this Policy, and at the expiration of each year of insurance to furnish a statement showing the total number of persons employed during the year, and to pay to the Corporation any additional premium due in respect of the persons so employed.

This Policy shall be in force for twelve calendar months from the date hereof.

Dated this day of 1907.

CONDITIONS INDORSED.

This reads comprehensively enough, but the insurer must not be content to rely on such simple wording. Let him look on the back or at the foot of his policy and carefully consider any further conditions indorsed thereon. It will be found in many cases that the conditions are so far reaching and complicated that he is left practically at the mercy of the insurance company as to whether or not they choose to pay any claim which may arise. The conditions indorsed on the policy should be as few and as clear as possible. The insurer should not agree to give notice of an accident to his servant within a fixed period of days; he should merely undertake to give notice within a reasonable

time. He should agree to render all reasonable assistance to the insurance company in the event of a claim arising and also to furnish a periodical statement of the persons in his employ, paying the additional increase in case of the number of servants being augmented. These conditions, if properly worded, are reasonable enough, but any additional conditions should be most carefully and closely checked and objected to if necessary. The wise insurer will therefore demand to see the full form of policy with the conditions indorsed before signing any proposal form. The indemnity should also cover "earnings" (not merely "wages") as well as all expenses of litigation.

Furthermore, it should be borne in mind that the mere act of insurance does not release an employer from his responsibility. The policy offers him a personal indemnity, but (except in the case of the insurer's own bankruptcy) this has nothing to do with the workman. He is entitled to look to the employer personally, and even if the insurance company should afterwards fail or be wound up the employer must go on paying to the injured workman what will be, in some cases, an annuity for life. The moral is, therefore, two-fold. Everyone should be careful to give the conditions of his policy the most serious attention, and should also be very careful not to insure with any company whose financial standing and reputation for fair dealing is not absolutely above reproach.

Finally, the insurer should take care in his proposal form to describe his workpeople by reference to their position and not by name. The description should be, for instance, head gardener, three under gardeners, cashier, clerk, &c., and Christian and surnames should on no account be given, as otherwise notice of every change would have to be given to the insurance company. H. Morgan Veitch.

HYBRID PLUM.

To Messrs. Laxton, of Bedford, we are indebted for specimens of their hybrid Plum, raised out of a Japanese Plum by pollen of a Peach. The flower generally is more like that of a Peach, but is sterile, owing to the abortion of the ovary, so that if all the flowers are similarly barren there would, of course, be no fruit, and the value of the hybrid in so far is nought, though as a flowering shrub it may be valuable. The drawing of the flowers made by Mr. Worthington Smith well shows the intermediate character of the hybrid, and should be useful to young gardeners desirous of understanding the construction of the Peach and Plum flowers, on which account a short explanation may be desirable. The upper series of illustrations shows in the left corner a cluster of Peach flowers of the large-flowered section, similar to those of a single Rose. Other Peaches are characterised by the presence of much smaller blossoms. To the right is shown the back of the flower, with the five sepals or calyx-lobes covered with fine hairs. The sepals encircle the bases of the five petals. In the centre of the cut is shown a flower sliced downwards through the centre and magnified two diameters. It is borne on a short stalk, provided all the way up with boat-shaped bracts. The vase- or cup-shaped flower-tube is well shown with the sepals, petals, and stamens springing from the margins of the tube, around and not beneath the ovary, as they would be in a Buttercup. At the bottom of the flower tube is seen the ovary prolonged into a long style, ending in a button-like stigma and containing a single ovule, the future seed. The oval pollen grains are shown as seen magnified 120 times; each is oval with a single furrow. In the centre row the Plum flowers are shown in a similar manner. It will be seen that, except in size and colour of petal, they are almost exactly like those of the Peach, so much so that the two flowers evidently belong to the same genus (*Prunus*). A difference is, however, observable in the presence of a comparatively long, slender stalk to the flower,

the bracts of which are at the base only and not extended up the stalk to the base of the flower as they are in the Peach. The difference in the size of the pollen-grains drawn to the same scale is also noteworthy.

The bottom of the illustration is devoted to the representation of the hybrid. The flowers are more like those of the Peach, but the long flower stalk is like that of the Plum. The calyx is shown as destitute of hairs, although they are present in both parents. The slice through the flower shows, as we have said, that the ovary is defective; the pollen, too, is small and irregular in size. The pollen of the hybrid might, however, be used in fertilising other flowers, though the hybrid itself is incapable, owing to structural defect, of being fertilised.

The illustration of the leaf of parents and hybrid is taken from the *Journal of the Royal Horticultural Society*.

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

SPRING FLOWERS.—Early Rhododendrons are flowering very freely this season. *R. Noble-anum*, *R. N. album*, *R. caucasicum*, *R. alta-clarense*, and *R. niveum* are now in full flower. Rhododendron campanulatum is just opening its flowers, and is quite hardy here when surrounded by large forest trees. It is remarkably fine when in flower. I have never seen so many flowers on our outdoor Camellias before, and they are earlier than usual, although up to the present many of the smaller plants have been unusually late. Hyacinths are now at their best, but the best show of "spring bedding" plants will not be for quite another fortnight. The Duchess Garden is now opened again to visitors daily on every day except Sundays, also the woodland walks and drives, but all vehicles are now prohibited. *W. H. Divers, Belvoir Castle Gardens, Grantham, April 13.*

CARNATION IMPOSTORS.—So long as persons will buy Carnation plants from hawkers, so long must they expect to be victimised. The sort of "trade" thus indulged in is by no means novel, and of my own knowledge for the past 40 years hawkers have had single Carnations raised annually from seed, but specially selected, because having broad foliage. Purchased wholesale at about 8d. per dozen, and under the local trade designation of "jacks," they have been retailed to credulous customers at prices varying from 3s. to 5s. per dozen. One grower at Feltham, Middlesex, used to raise and plant out every year from 15,000 to 20,000 of these "jacks," and did a wonderful trade with them in the spring. This grower invariably selected and lifted to plant in a compact block for seed production, about 200 plants that had the broadest leafage, as these maintained that character of the strain and thus helped the hawkers to impose them on purchasers as choice named varieties. *A. D.*

THE AGAPANTHUS AS A HARDY PLANT.—*Agapanthus Mooreanus*, according to botanists, is but a form of *A. umbellatus*, but from a garden point of view it is quite distinct, having narrower leaves, more slender stems, and smaller flowers. It is also much hardier; I know of its flourishing as a hardy plant in gardens well north, and even in exposed situations. In my former and present gardens it is quite hardy and increases with much freedom, without any protection, in a somewhat dryish soil. *A. umbellatus*, the type, is, however, more tender, and it is not everywhere in Scotland that it will prove hardy. In the south-west it is fairly hardy, and I was much interested the other day in seeing how well it has survived a most trying winter in the garden of Captain Hope, R.N., at St. Mary's Isle, Kirkcudbright. At St. Mary's Isle the *Agapanthus* are planted rather deeply at first, so that the frost has little effect until the plants become established. The *Agapanthus* should be more largely planted and cultivated as a hardy plant in the milder districts of these islands. *S. Arnott, Dumfries.*

SCOLIOPUS BIGELOWI.—This plant is now flowering in the Alpine garden at Leonardslee. The flowers are solitary and on radical peduncles, which are 3 to 5 inches in length.

Their colour is purple and green, with purple stripes running down the petals. The plants here are cultivated under a cool rock, which affords them a certain degree of shelter. *W. A. Cook.*

TO PRUNE, OR NOT TO PRUNE.—I was much interested in the leading article (p. 204) on this subject, and am quite in accord with the views therein expressed. A moderate amount of pruning, including the removal of all cross branches, the pinching of shoots, and the thinning of the growths to admit light and air, is beneficial. During the past ten years I have planted hundreds of young fruit trees of all descriptions—

examples of non-pruning in the neglected orchards of the country. Is this a system to be encouraged? On taking charge of a garden some years ago in a good fruit-growing district, I succeeded in convincing an advocate of non-pruning of the fallacy of his belief, and the following autumn I made a start, thoroughly thinning and cleaning the trees, the result in two or three years being marvellous, and the trees were considered an object-lesson in the district. In pruning these trees I left as much young wood as possible, being a believer in the extension system where practicable. *A. D.* (p. 223) suggests trials of the two systems, but have we not sufficient examples all around us in the unpruned

FIG. 109.—HYBRID PLUM-PEACH.

orchard, bush, and wall trees, the majority being Apples, and, having planted them, have pruned them, and afterwards successfully exhibited the fruit in open competition at the national fruit shows. I am not an advocate, however, for practising pruning such as is sometimes done, when every particle of young wood is cut away. A point I do not understand in Mr. Spencer Pickering's statement (quoting from page 223) is "when there is no pruning, the crops are twice as great as where moderate pruning is adopted, and four times as great as where hard pruning is practised." It is not quantity of fruit that pays, but quality, and one can see on every side

orchards, on the one hand, and the moderately-pruned trees of the practical market-grower on the other? I imagine he is right in thinking "that many of your readers would ask if the game is worth the candle." *Moderate Pruner.*

CALTHA POLYPETALA.—This is a form of *Caltha palustris*, but it is much larger than the type both in foliage and flower. It grows better in the water than out, and if planted near the bank of a lake or pond it will soon increase rapidly. Being early in flower, it makes a display when flowers are greatly appreciated. *W. A. Cook.*

MISTLETO.—The Lime tree mentioned by Mr. A. Dean, on p. 240, as bearing contorted growths caused by this parasite, was cut down some three years ago, owing to its dying condition. Even more curious examples were the three large Poplars, over 90 feet high, standing some 800 yards to the south-west of Dropmore House. The main branches of these huge trees were, in some cases, covered with masses of the parasite. In these cases all top growth ceased, and the limb gradually died away. Mr. Elwes will doubtless remember these old trees, for he was very interested in them when he visited Dropmore. The Mistletoe grows here on the Lime, Poplar, Thorn, Acacia and Apple. *Chas. Page, Dropmore Gardens.*

TREE PÆONIES IN POTS (see also p. 253).—I had pleasure in reading, p. 224, of the exhibit of Tree or Moutan Pæonies staged at the Horticultural Hall on April 2. I do not know of more charming plants at this season of the year for placing in a drawing-room, corridor or conservatory. We have grown them at Dingley for five seasons and I think they are admired more each year. Our plants came direct from Japan, and they were potted into 8 and 9-inch pots in a mixture of peat, loam, leafmould, sand, and old

SOCIETIES.

ROYAL HORTICULTURAL.

APRIL 18.—An unusually extensive exhibition was made in the Vincent Square Hall at the fortnightly meeting on Tuesday last. The tables and floor of the building, including the recesses, were well furnished with contributions that represented almost every plant and flower now in season. There were many collections of choice Narcissus, and it is hardly likely that these flowers will be shown so well in this hall on more than one further occasion this season. At the next meeting, however, they should constitute a prominent feature. This committee recommended two Awards of Merit to novelties, the varieties so distinguished being *Queen of the West* and *Atalanta*.

Orchids were plentiful and brilliant; one novelty was selected by the ORCHID COMMITTEE to receive a First-Class Certificate, and to three others the Award of Merit was recommended.

The FLORAL COMMITTEE recommended one First-Class Certificate and five Awards of Merit. An extensive exhibit of Narcissus growing in the form of a grass-covered mound was an

son, C. E. Pearson, Chas. E. Shea, W. P. Thomson, E. H. Jenkins, W. J. James, F. Page Roberts (Rev.), C. T. Druery, Geo. Gordon, George Paul, and R. Hooper Pearson.

Messrs. J. HILL & SON, Barrowfield Nurseries, Lower Edmonton, staged a collection of choice exotic Ferns. The exhibit was rich in Adiantums, including the rare *A. sancta Catherinae*, somewhat like *A. tenerum Farleyense*; *A. curvatum*, with branched fronds and having pinnæ not unlike those of a *Nephrolepis*; *A. macrophyllum*, of splendid colouring; there were also *Lomaria gibba*, with a handsome head of new fronds, and many others of equal beauty. (Silver Banksian Medal.)

Messrs. CRAGG, HARRISON, & CRAGG, Merivale Nurseries, Heston, Middlesex, showed a clean, healthy collection of succulent plants in small pots, representative of many of the genera of these curious plants. (Bronze Flora Medal.)

Messrs. THOS. CRIPPS & SONS, Tunbridge Wells, Kent, made a fine show with large-flowered Clematis and ornamental Acers (Maples). Among the Clematis were the beautiful *Nellie* and *Marcel Moser*, also *Symeana*, with heliotrope-coloured flowers; *Lady Caroline Nevill*, also heliotrope, but with a darker rib

LEAF OF PEACH.

(LEAF OF HYBRID.

LEAF OF PLUM.

(From the *Journal of Royal Horticultural Society*.)

mortar rubble. The last two seasons the plants have been well top-dressed only, and the drainage overhauled, but when growing they have been fed with various liquid manures. The specimens have from three to five blooms on a plant. The following varieties, with their colours and size, will be found excellent for pot culture: *Gabisan*, single, white, tasselled yellow anthers, 10 inches across; *Kumoi-dsuru*, deep purple, 12 inches; *Shiro-kagura*, white, purple feathers at base, 10 inches; *Kumoma-no-tsuki*, rich port wine colour, 9 inches; *Michi-shiba*, deep carmine, 13 inches; *Renkaku*, white, 12 inches; *Kagurajishi*, pink, 12 inches; *Ruriban*, rich purple, 12 inches; *Adzumakagami*, deep carmine, 12 inches; *Shoki-kagura*, satiny rose, 12 inches; *Saigo-sakura*, delicate satin pink, 10 inches; *Adzuma-nishiki*, crimson, shaded scarlet, fringed white, yellow base, 9 inches across. The greater number of the varieties have golden and primrose coloured anthers, which greatly add to the beauty of the flower. *F. Clipstone, Dingley, Market Harborough.*

attempt at realism not previously made at these shows. It was very effective.

The FRUIT AND VEGETABLE COMMITTEE made no award. An exhibit of vegetables was shown by Miss M. H. DODGE, Loseley Park, Guildford (gr. Mr. R. Staward). Several new Apples were shown, also a new Rhubarb named *Collis' Ruby*; these, with a box of fruits of Strawberry Vicomtesse Héricart de Thury, from the gardens of A. W. SUTTON, Esq., Woolhampton, representing all that came before the committee.

At the meeting of Fellows, held in the afternoon, 60 new candidates were added to the roll of the Society, and two societies affiliated, after which Mr. R. H. Curtis lectured on "Rainfall in its Relation to Horticulture."

Floral Committee.

Present: W. Marshall, chairman; and Messrs. Geo. Nicholson, Jno. Green, T. W. Turner, C. R. Fielder, J. W. Barr, R. C. Notcutt, Jas. Douglas, J. F. McLeod, J. Jennings, Jas. Hudson, Arthur Turner, Chas. Dixon, W. Cuthbert-

son, C. E. Pearson, Chas. E. Shea, W. P. Thomson, E. H. Jenkins, W. J. James, F. Page Roberts (Rev.), C. T. Druery, Geo. Gordon, George Paul, and R. Hooper Pearson.

Messrs. J. HILL & SON, Barrowfield Nurseries, Lower Edmonton, staged a collection of choice exotic Ferns. The exhibit was rich in Adiantums, including the rare *A. sancta Catherinae*, somewhat like *A. tenerum Farleyense*; *A. curvatum*, with branched fronds and having pinnæ not unlike those of a *Nephrolepis*; *A. macrophyllum*, of splendid colouring; there were also *Lomaria gibba*, with a handsome head of new fronds, and many others of equal beauty. (Silver Banksian Medal.)

Messrs. CRAGG, HARRISON, & CRAGG, Merivale Nurseries, Heston, Middlesex, showed a clean, healthy collection of succulent plants in small pots, representative of many of the genera of these curious plants. (Bronze Flora Medal.)

Messrs. THOS. CRIPPS & SONS, Tunbridge Wells, Kent, made a fine show with large-flowered Clematis and ornamental Acers (Maples). Among the Clematis were the beautiful *Nellie* and *Marcel Moser*, also *Symeana*, with heliotrope-coloured flowers; *Lady Caroline Nevill*, also heliotrope, but with a darker rib

exhibit the same firm showed the dwarf Cineraria Antique Rose, a pleasing shade; the large, open-spathed Richardia Childsii grandiflora; varieties of Anthurium Scherzerianum, including some with spotted spathes; the Gloriosa jasminiflora, like a white-flowered Honeysuckle, and many other desirable plants. (Silver-Gilt Flora Medal.)

Mr. H. B. MAY, Dyson's Lane Nurseries, Upper Edmonton, displayed Pelargonium Clorinda—some standard trained; the variegated form of Funkia Sieboldi, a popular parlour plant; hardy Ferns, showy Clematis, dwarf Roses, Pansies, and Statice profusa.

Messrs. H. CANNELL & SONS, Swanley, Kent, showed Zonal Pelargoniums better than ever. They had also some improved varieties of Primula obconica, a batch of Begonias of the semperflorens section, and a bright-flowered Tropaeolum named Kentish Fire. (Silver-Gilt Banksian Medal.)

Messrs. SUTTON & SONS, Reading, exhibited plants of their dwarf strain of Cinerarias, all of blue and pink shades: the dense, compact inflorescences quite covered the sturdy plants. In the same exhibit was a batch of the wild Ranunculus of Palestine, according to some authorities the Lily of the Field of Scripture; some pink Frezias, and a batch of Lachenalia tricolor. (Silver-Gilt Banksian Medal.)

A batch of Hippeastrums, all unnamed varieties, was staged by Mr. J. KINNICK, Edgbaston, Birmingham. Taken collectively, the group made a fine display. (Silver Flora Medal.)

Sir EDMUND LODGE, Leonardslee, Horsham, Surrey (gr. Mr. W. A. Cook) occupied much space with Magnolias, Rhododendrons, Camellias, Magnolias, and Daffodils cut from the open. There were no fewer than 18 species, and varieties of Magnolias, the most interesting being a rose-coloured form of M. stellata. The varieties of Rhododendron and Camellia were very numerous. An interesting plant shown was Larix Griffithi, with fresh cones. (Silver Banksian Medal.)

Messrs. HUGH LOW & CO., Bush Hill Park, Enfield, London, N., showed greenhouse flowering plants in variety. The brush-like spikes of Metrosideros floribunda were conspicuous objects; the flowers of Lotus peltorhynchus hung in festoons over the table, and above were Acacias, Ericas, Cyclamen, Eriostemon nerii-folium, Gerbera Jamesoni, and other greenhouse plants. A brilliant array of winter-flowering Carnations completed the display. (Silver Flora Medal.)

Messrs. R. and G. CUTHBERT, Southgate, London, N., set up a fine bank of forced flowering trees and shrubs, having heavily-flowered Lilacs, standard trained; and species of Cerasus over Azaleas, dwarf Lilacs, with Maples, Ferns, and Grevillea robusta interspersed. (Bronze Banksian Medal.)

Mr. W. E. WALLACE, Dunstable, Beds., again displayed the charming Rose Richmond, in company with a few others, including Mme. Abel Chatenay, Lady Roberts, Pharisæer, &c. (Silver Banksian Medal.)

Messrs. FRANK CANT & CO., Braiswick Rose Nurseries, Colchester, had tall plants of Rambler Roses of the varieties Wedding Bells and Philadelphia Rambler, and in front a few blooms of tea and hybrid varieties. The pillar Roses were abundantly flowered, and of the type of Crimson Rambler.

Seldom before have forced Roses been better displayed than were those shown by Mr. GEO. MOUNT, Canterbury. The freshness of the blooms was remarkable, and for vigour of stem and foliage, substance of bloom, brightness of colour and taste in displaying them, nothing but the highest praise can be bestowed. The exhibit required a large table for its accommodation, and it was crowned in the centre with a tall epergne, in which were the white Frau Karl Druschki and the red Liberty intermixed. A bank of Catherine Mermet and La France on either side of the centrepiece, but sufficiently far away to allow of the continuity being broken with dwarf vases, and with boxes in front, and every bloom a specimen, repeated with other banks of Mrs. John Laing and Ulrich Brunner afforded a veritable feast of Roses. A selection of the varieties included Mme. Abel Chatenay (charming in the bud), Anna Olivier,

Bridesmaid, the new Richmond, and Prince de Bulgarie. (Gold Medal.)

Messrs. W. PAUL & SON, Waltham Cross, Herts, exhibited pillar Roses of great beauty; tall plants of the white Waltham Bride were shown with the flowers hanging in great clusters, and near by was the charming single white Nymph, studded along its drooping sprays with the white blossoms. A batch of the rich red Warrior in the centre of the group gave a touch of colour to the display, and below were cut blooms of new varieties of Continental origin. A climbing variety of merit is Crepuscule, the flowers are somewhat of the shade of the popular W. A. Richardson. (Silver Flora Medal.)

Messrs. W. CUTBUSH & SONS, Highgate, London, N., showed Polyantha Roses of such kinds as Mrs. F. W. Flight and Mrs. W. Cutbush, and a naturally-arranged exhibit of Alpine and rock-garden plants. The exhibit of these latter plants was crowned with Azaleas, Spiræas, Magnolias, Rhododendrons, and other dwarf shrubs. Some interesting plants were in flower, Edraianthus serpyllifolius has procumbent growths terminating in dark blue Campanula-like flowers; Incarvillea grandiflora has large rose-coloured flowers; Xanthoceras sorbifolia was shown well. Adjoining this display, Messrs. CUTBUSH had Carnations in all the leading varieties of the winter-flowering type. (Bronze Flora Medal.)

Messrs. GEO. JACKMAN & SON, Woking, Surrey, showed Alpine plants in variety, among which was a batch of Primula Cashmeriana, nicely flowered. A conspicuous plant was Clematis indivisa lobata. We also noticed the double-flowered Caltha palustris, Amelanchier canadensis, Peaches, Magnolias, Ribes, &c.

Craven Nursery Co., Clapham, Yorkshire, showed a collection of Alpines very rich in Primulas—P. Clusiana, P. nivalis, P. viscosa, P. marginata, P. calycina, P. spectabilis, and others, all in the best condition of culture.

A small exhibit of Alpines was shown by Messrs. JOHN PEED & SON, West Norwood; and also by the Misses HOPKINS, Barming, near Maidstone, Kent.

Messrs. R. WALLACE, Kilnfield Nurseries, Colchester, showed hardy plants in great variety. We noticed the dwarf Tulipa Lownei, with pale rose-coloured petals; Mertensia virginica, Primula verticillata in several forms, Daphne cneorum, and Tulips, Fritillarias, Crown Imperials, Daffodils, and a host of other spring flowers, all in the best condition.

Mr. G. REUTHE, Hardy Plant Nursery, Keston, Kent, displayed seasonable Alpine flowers, many trusses of hardy Rhododendrons of richly-coloured varieties, several Camellias, Daffodils, Primroses, &c. An interesting plant was observed in Lathraea purpurea, the specimen being parasitic, in this instance, upon the Willow. (Bronze Flora Medal.)

Mr. MAURICE PRICHARD, Christchurch, Hants, exhibited an assortment of early-flowering hardy and Alpine garden plants. He had the double Marsh Marigold in good condition, Erythronium revolutum Watsoni, Clematis balearica, the double-flowered Celandine, Ribes speciosum, Crown Imperials, Anemones, Primroses, including the rich crimson variety Pompadour, &c. (Bronze Flora Medal.)

Messrs. DOBBIE & CO., Rothesay, N.B., and Mark's Tey, Essex, showed a fine strain of Polyanthus in varieties named from their colours, some improved forms of Primula Sieboldi, and large, rich-coloured Pansies and Violas, all of first-class culture.

Mr. JAMES DOUGLAS, Edenside, Great Bookham, Surrey, displayed between 50 and 60 choice Auriculas, almost all of his own raising. Some new kinds will be found under Awards, and of the others the best were Standard Bearer, May Day, Lycidas, Brunette, Bronze, Sea Eagle, Admiration, Zingara, and Brightness.

Messrs. T. S. WARE, Ltd., Ware's Nursery, Feltham, showed a collection of hardy flowers, including Alpine species, and some good blooms of Carnations. The rare flowering Satyrium coriifolium was represented by three plants in flower. We also noticed Lewisia Tweediei, with campanulate flesh-tinted flowers; Dodecatheon Hendersoni, Iris fimbriata (syn. japonica), &c. (Bronze Flora Medal.)

Mr. A. R. UPTON, Hardy Plant Nursery, Guildford, showed pans of seasonable hardy flowers, including a fine specimen on Anemone ranunculoides heavily flowered.

Mr. GEO. KERSWILL, St. Thomas, Exeter,

exhibited a large box containing the peerless Gentiana acaulis in exceptionally good condition.

Lady HINDLIP, Hindlip, Worcester (gr. Mr. Bayley), exhibited a dozen vases of Sweet Peas. Hon. WALTER ROTHSCHILD, Tring Park, Tring (gr. Mr. Dye), showed an inflorescence of Crinum scabrum. The umbellate inflorescence carried four flowers; the flower-segments are white, with a reddish-brown veining down the centres, and with recurving tips.

Mrs. BROCKLEHURST, Sudeley Castle, Winchcombe, showed three pot plants of Tritonia crocata Prince of Orange; the name is indicative of the colouring.

AWARDS.

FIRST-CLASS CERTIFICATE.

Agapeles speciosa.—This is the new red-coloured species figured in our last issue. It was recommended a Botanical Certificate by the Scientific Committee at the previous meeting, when it was also submitted to the FLORAL COMMITTEE under the name of Thibaudia sp., but both bodies withheld any award until the species had received a name. Shown by J. T. BENNETT POE, Esq., Holmwood, Cheshunt.

AWARDS OF MERIT.

Auricula Brightness.—A very pretty purple-coloured Alpine variety, similar to Standard Bearer.

A. Miss Berkeley.—An Alpine variety of very large size and good form; colour, maroon purple with white eye. Both varieties were shown by Mr. JAS. DOUGLAS, Edenside Nurseries, Bookham.

Freesia Tubergeni Amethyst.—This variety has pale lilac-coloured flowers of considerable size, being much larger and paler than those of F. Tubergeni, which latter is described as from a cross between F. refracta alba and F. Armstrongii. The variety Amethyst is from F. Tubergeni crossed back again on F. refracta alba. Shown by C. G. VAN TUBERGEN, Jux., Haarlem, Holland.

Primula Cockburniana.—This is the small orange-flowered Primula which was figured and described in our issue for May 27, 1905, p. 331. It is one of the plants introduced through the agency of Messrs. JAS. VEITCH & SONS from Western China. The plant has already received a Botanical Certificate from the Scientific Committee. So far as it has been proved, the value of the species is in its colour, as it is a weak grower. It may be expected that use will be made of it for crossing with other species. Shown by Messrs. JAS. VEITCH & SONS, LTD.

Rose Pharisæer.—This is one of the best pink bedding Roses, and is generally well known. Shown by Mr. W. E. WALLACE, Eaton Bray Nurseries, Dunstable.

CULTURAL COMMENDATION.

Tchihatchewia isatidea.—Lady EMLYN, Frensham Hall, Haslemere, showed a pot plant of this Cruciferous species from Armenia. A figure of the species was given in *Bot. Mag.*, tab. 7608, from a plant which flowered at Kew. The plant shown was considered to be representative of first-class cultivation. We hope to refer to the species in a subsequent issue.

Narcissus Committee.

Present: H. B. May, Esq. (chairman); and Messrs. A. Kingsmill, Robert Sydenham, A. R. Goodwin, W. F. M. Copeland, J. Pope, G. Reuthe, Alex. M. Wilson, R. Wallace, W. T. Ware, P. R. Barr, F. W. Currey, G. H. Engelheart (Rev.), Chas. Dawson, P. D. Williams, G. W. Leak, and C. H. Curtis (hon. secretary).

A group of Narcissi staged by Miss F. W. CURREY, Lismore, Ireland, attracted much attention, not merely because of its extent, but also on account of the choice flowers it contained. Among the choicest and best was the very distinct Duke of Leinster, an incomparabilis type, having a large spreading cup of pure and uniform orange. It is not a flame colour or one of those varying tones of orange, pale at the base, with a more intense coloured margin, but is of a uniform shade throughout. White Knight, the whitest of all white Ajax kinds, on opening, is a drooping flower of refined and beautiful appearance. Then there was the Geraldine, an incomparabilis, with its fiery flame-coloured cup and spreading creamy wings. Maggie May, Chaucer (poeticus), and Atalanta (see Awards). (Silver-Gilt Banksian Medal.)

Mr. CHARLES DAWSON, Gulval, Penzance; also

staged a very choice collection. Ibis (poeticus), Homespun (figured in our last issue), Lord Roberts (a fine Ajax), White Slave (of the Engleheartii type, with yellow or lemon cup), Cossack, Red Cap, and Buttercup, all distinct and beautiful flowers. (Silver-Gilt Flora Medal.)

Messrs. HOGG & ROBERTSON, Dublin, had a large assortment of standard varieties of good quality.

Miss R. SPURRELL, Bessingham, Norwich, had a small set, in which Mrs. Edmund Harvey, a Leeds flower, with delicately margined cup of citron, was noted; it is a delicate and pretty flower.

Messrs. BARR & SONS, Covent Garden, had a good display of the best kinds, also several novelties. Of the latter, Seraphim is a big, pale bi-color, a huge Weardale (with paler cup, but in every way a giant), Loveliness and Peter Barr (both white Ajax kinds), Stradivarius (with the drooping triandrus flowers), Horace (a fine Poet's Daffodil), and Janet Image, Hamlet, &c. (Silver Flora Medal.)

Rev. G. H. ENGLEHEART, Dinton, Hants, had an assortment of white seedling forms.

Rev. G. P. HAYDON, Westbere, Canterbury, had perhaps the most beautiful novelties in the show, and they were more interesting, because the parentage in not a few instances was given. Pearl of Kent, for example, seen for the first time a year ago, is a fine drooping white Ajax, a strong flower in every way, and, we were informed, it is a splendid grower. Dropmore, also an Ajax kind, has the most pronounced droop of any trumpet kind we know. Its parents are Monarch and Mme. de Graaff. Our Bessy, the result of crossing Mme. de Graaff and the Pyrenean poeticus, has produced a pure Nelsoni, while China Ware and Leiden Jar are other distinct and beautiful kinds. (Barr's Silver Cup.)

Mr. F. HERBERT CHAPMAN, Rye, obtained a Silver-Gilt Banksian Medal for an assortment of choice kinds, in which culture and freshness were points of the highest importance. The finest flowers were White Queen, Weardale Perfection, Lady Margaret Boscawen, King Alfred, and Virgil.

Messrs. POPE & SON, King's Norton, contributed many good sorts, the large-flowered King's Norton being of the number. (Silver Banksian Medal.)

Sir JOSSLYN GORE, Bart., Sligo, secured a Silver Flora Medal for a choice assortment, in which the several sections of Narcissi found many representatives.

Messrs. BULL & SON, Chelsea, displayed a general collection of well-known varieties.

Some interesting and beautiful seedling varieties were presented by Mrs. BACKHOUSE, Sutton Court, Hereford. The more remarkable were Zoe, a giant flower of the Queen of Spain type, and Lord Kitchener, a very handsome bi-color of Sir Watkin form, and these, with White Witch and Snowdon, were of exceptional size and great merit.

Messrs. R. and G. CUTHBERT, Southgate, arranged a display suggestive of a grass bank or slope studded with Daffodils. Real turves of grass were used, which made the exhibit appear very natural.

A fine assortment of Daffodils was staged by Messrs. R. H. BATH & CO., LTD., Wisbech, and here many of the finest things of commerce were to be seen. (Silver Flora Medal.)

Messrs. WALLACE & CO., Colchester, also staged a very nice lot of these flowers in the newer sorts.

Sir E. LODER, Bart., Leonardslee, Horsham (gr. Mr. W. A. Cook), had a beautiful lot of the better-class varieties, White Queen, King Alfred, and other handsome sorts being staged in big bunches.

AWARDS OF MERIT.

Narcissus Queen of the West.—A giant self-yellow Ajax kind of noble proportions. The huge trumpet or crown recalls King Alfred, more especially in the handsome reflex of the brim, while the segments of the perianth are inclined to be flat and spear-shaped. The colour is of lemon yellow, and the plant is of giant stature. The parentage is not known, though there is more than a suggestion of *N. maximus* in the crown. It is certainly one of the biggest flowers we have seen. From WALTER T. WARE, Ltd., Bath.

Narcissus Atalanta.—An Irish raised Daffodil of great beauty and charm; a flower in which

all that is good in the lovely Mme. de Graaff is seen. The perianth segments are white—not the whiteness seen in poeticus—and of large size, but it is, we think, in the creamy trumpet or crown and with the sturdy bearing of the flower generally that much of the beauty exists. More drooping than Mme. de Graaff, and larger, it is a flower full of grace and refinement. From Miss F. W. CURREY, Lismore, Ireland.

Orchid Committee.

Present: J. Gurney Fowler, Esq. (in the Chair); and Messrs. Jas. O'Brien (hon. sec.), Harry J. Veitch, De B. Crawshaw, F. M. Ogilvie, W. Boxall, F. J. Lambury, G. F. Moore, C. J. Lucas, R. G. Thwaites, T. W. Bond, W. P. Bound, A. Dye, H. T. Pitt, A. A. McBean, H. G. Alexander, W. Cobb, J. Charlesworth, W. H. White, W. H. Young, H. A. Tracy, W. Bolton, W. A. Bilney, H. Ballantine, and F. J. Thorne.

Messrs. CHARLESWORTH & CO., Heaton, Bradford, staged a group composed principally of hybrid Orchids of their own raising, *Odontoglossum* being freely represented. In the centre was a varied selection of *O. Rolfeae* varieties, and interspersed were fine forms of *O. Ossulstoni*, *O. ardentissimum*, *O. Othello*, and other hybrids; good forms of *O. crispum*, *O. Wilckeanum*, &c. There were also a number of showy *Laelio-Cattleya* Wellsiana, an equally good lot of *L.-C. Dominiana* and *L.-C. Mercia*, and a dark form of *Cymbidium l'Ansoni*, the new *Miltonia Hyeana*, *Cattleya intermedia alba*, *Masdevallia Chestertoniana*, some nearly white *Brasso-Cattleya Digbyano-Schröderae* and other fine hybrids. (Silver-Gilt Flora Medal.)

Messrs. JAS. VEITCH & SONS, LTD., King's Road, Chelsea, staged an effective group, the leading plant in which was their superb *Brasso-Cattleya-Laelia Veitchii* (see Awards). Other special plants were the handsome *Odontoglossum ardentissimum* *Lamus*, for which they gained an Award of Merit, March 28, 1905; a very dark and brightly-coloured *Laelio-Cattleya Canhamiana*; a specimen *Dendrobium thyrsiflorum* with six spikes; a good selection of *Cattleya Schröderae*, showy *Odontoglossum*, and other handsome species. (Silver Flora Medal.)

J. GURNEY FOWLER, Esq., Glebelands, South Woodford (gr. Mr. Davis), staged a very fine group of *Cattleya Schröderae*, the plants in some cases bearing ten to eighteen flowers, which, in the different varieties, varied from bluish-white segments and yellow throat to light rosy-lilac, with an orange-coloured disc to the lip, and all were fragrant. One exceptionally distinct variety had a large violet crimson blotch on the lip. In the back of the group were finely-flowered plants of *Dendrobium Wardianum*; the distinct *Cattleya intermedia* Fowler's variety. We also noticed the violet-lipped *Zygopetalum Perrenoudi* and the handsome variety "Cecil Rhodes"; the beautiful white-petalled *Cattleya Luddemanniana* Stanleyi, which had previously received a First-Class Certificate; and the large, creamy-white *Cymbidium* J. Gurney Fowler of unrecorded parentage, but one of the finest hybrid *Cymbidiums*; the broad lip bears a zone of dark purple spots. (Silver Flora Medal.)

C. J. LUCAS, Esq., Warnham Court, Horsham (gr. Mr. Duncan), showed excellent forms of *Odontoglossum crispum*, principally of the white type, but a few were spotted. *O. crispum* Jennie is a pretty variety, with spotting on the sepals. The group also included *Odontoglossum Othello* (see Awards), two pretty forms of *O. Ossulstoni*, *O. Rolfeae*, and *O. Hallii*. (Silver Flora Medal.)

H. S. GOODSON, Esq., Fairlawn, Putney (gr. Mr. Day), showed the very remarkable *Odontoglossum ardentissimum* "Herbert Goodson" (see Awards), some finely-coloured *Laelio-Cattleya luminosa* and *L.-C. Dominiana*; a plant of *Angræcum sesquipedale*, with five flowers, several specimens of the white *Cattleya intermedia nivea*; *Laelio-Cattleya highburyensis*, &c. (Silver Flora Medal.)

Messrs. ARMSTRONG & BROWN, Tunbridge Wells, put up an extensive group, in which was a varied selection of hybrid *Dendrobiums* and *Cypripediums*. Forms of *Dendrobium Venus* and *D. Sibyl* were specially attractive; other plants noticed were *Odontoglossum excellens*, some hybrid *Zygopetalums*, *Zygo-Colax*, and *Cypripedium Maudiae*. (Silver Flora Medal.)

Messrs. SANDER & SONS, St. Albans, showed the beautiful *Cymbidium Sanderæ* (C. Parishii *Sanderæ*), illustrated in the *Gardeners' Chronicle*, May 28, 1904, p. 838.

R. I. MEASURES, Esq., Camberwell (gr. Mr. Smith), showed two specimens of his pretty hybrid *Cymbidium Lowianum*.

Messrs. HUGH LOW & CO., Bush Hill Park, Enfield, staged a group in which were a fine plant of *Cattleya amethystoglossa*, several good *C. Schröderae*, *Cattleya Lawre-Mossiae*, *Lycaste Skinneri alba*, *Bifrenaria Harrisoniae*, *Coryanthes speciosa* and hybrid *Cypripediums*, the most remarkable of which was *Cypripedium E. J. Seymore* (callosum x *Prewettii*). A very large flower of distinct shape, the large upper sepal being pale green with a white margin and marked with dark purple lines; the decurved and broad petals and lip are tinged with brownish rose.

Messrs. STANLEY & CO., Southgate, arranged a small group, in which were very good *Cattleya citrina*, *Oncidium Marshallianum*, *O. sarcodes*, *Odontoglossum crispum*, *O. Edwardii*, &c.

FRANCIS WELLESLEY, Esq., Westfield, Woking (gr. Mr. Hopkins), sent *Laelio-Cattleya stellata* (L. xanthina x C. intermedia alba), a hybrid approaching L. xanthina in size and shape, but with greenish sepals and petals and white lip, with a rose blotch on either side of the front lobe and with some rose veining.

J. T. BENNETT-POE, Esq., Holmewood, Chesham (gr. Mr. Downes), showed *Cymbidium Colmaniae flavescens*, a yellowish-white hybrid.

Major G. L. HOLFORD, C.I.E., C.V.O. (gr. Mr. Alexander), showed several fine Orchids (see Awards), including *Brasso-Cattleya Cordelia* (C. intermedia x B. Digbyana).

DE B. CRAWSHAY, Esq. (gr. Mr. Stables), sent the new *Odontoglossum lago* (Harryanum x *Hunnewellianum*) and the fine *O. triumphans* *Imperator* and *Theodora*.

AWARDS.

FIRST-CLASS CERTIFICATES.

Brasso-Catt.-Laelia x Veitchii (L. purpurata x B.-C. Digbyano-Mossiae), from Messrs. JAS. VEITCH & SONS. A grand hybrid comparable to very fine *Laelio-Cattleya callistoglossa*, but with the richly-coloured labellum fringed. Sepals and petals silver-white, tinged with rosy-lilac. Lip large, the disc light chrome-yellow, and base with purple lines; the broad front is rose purple, merging lighter towards the fringed margin.

Sophr.-Laelia Phroso superba (L. Jongheana x S.-L. lata *orpetiana*), from Major G. L. HOLFORD, C.I.E., C.V.O. (gr. Mr. Alexander). A charming flower of a uniform mauve-crimson colour, with orange disc to the lip.

Odontoglossum ardentissimum "Herbert Goodson," from H. S. GOODSON, Esq., Fairlawn, Putney (gr. Mr. Day). The finest form of *O. ardentissimum*, with a very heavily-blotched flower, equal to a good blotched *O. crispum*. All the segments are broad and nearly covered with claret-crimson blotches, the margin and dividing lines being silvery-white.

AWARD OF MERIT.

Odontoglossum Othello (Harryanum x *Adrianae*), from C. J. LUCAS, Esq. (gr. Mr. Duncan). A hybrid with the dark colouring of a good *O. Harryanum*, but of better form. Sepals and petals yellowish-white, heavily blotched with chocolate colour; lip white, with purple markings at the base.

CULTURAL COMMENDATION.

To Mr. H. G. Alexander, Orchid grower to Major HOLFORD, for a noble specimen of *Cattleya Mendelii*, Westonbirt variety, with 16 flowers. It is a grand flower, with front of the lip shaded an intense purple; and for a specimen of *Odontoglossum Adrianae* Lady Wantage, grown from a single pseudo-bulb, and bearing six spikes, having together 105 flowers, one spike bearing 26 fine blooms.

To Mr. W. H. White, Orchid grower to Sir TREVOR LAWRENCE, Bart., Burford, for two splendid inflorescences of *Phalaenopsis amabilis* (grandiflora), one having three branches bearing 13, 14, and 18 flowers respectively. The single spike had 21 flowers, and all were of extraordinary size.

THE DEVON DAFFODIL.

APRIL 9.—This society opened its fourth annual show in the Guildhall, Plymouth, on the above date. The exhibition was in every sense a success, the entries exceeding those of the preceding year by nearly a hundred. Twelve

exhibitors competed in the premier Devon Narcissus class; while in two other classes there were 19 entries. The open classes were also well filled, the same Cornish growers who were successful at Truro carrying off the majority of the prizes. Spring flowers other than Narcissi were well shown, and many of the pot plants were exceptionally fine, Cyclamen and Zonal Pelargoniums especially being marvels of culture. We mention a few of the more prominent exhibits:—

Collection of 30 varieties of Daffodils.—1st prize, Mr. P. D. WILLIAMS, with a stand as good as that which occupied the premier position at Truro, Peregrine, Lucy, Étoile, Incognita, Famille Verte, Beacon, Bullfinch, Waxwing, Diana, Chaffinch, Pure Gold, Horace, Will Scarlet, Maximus, Inga, and Lord Roberts being very fine.

A group of Daffodil seedlings exhibited not for competition by Mr. J. C. WILLIAMS was certainly the most interesting feature of the show. The 15 varieties staged included Magni-coronati, white and yellow; two beautiful white Medio-coronati, one of which was said by the judge to be the finest flower in the show; and Parvi-coronati, with spreading orange-scarlet cups. For this stand an Award of Merit was given.

Best group of Rhododendron blooms.—1st prize, Mr. D. H. SHILSON, with 225 trusses of 75 different varieties, this exhibit creating a brilliant effect. A Certificate of Merit was awarded to the varieties Duke of Cornwall and Duchess of Cornwall.

Finest truss of Rhododendron.—1st prize, Mr. D. H. SHILSON, with R. Harrisii.

Group of hard-wooded flowering shrubs.—1st prize, the Earl of MOUNT EDGUMBE, with a collection including Correa cardinalis, Wistaria sinensis, Magnolia conspicua, Daphne Mezereum, Cerasus J. H. Veitch, Forsythia intermedia, Spiræa Thunbergii, Correa bicolor, Prunus triloba fl. pl., Acacia decurrens, Pyrus japonica, Jasminum primulinum.

Collection of 20 varieties of hard-wooded flowering shrubs.—Silver cup, Mr. T. B. BOLITHO, whose group contained Chorizema Lowi, Pittosporum undulatum, Photinia serrulata and several Magnolias.

Among the pot plants the 1st prizes in the classes for six Cyclamen and six Zonal Pelargoniums, won respectively by the Misses CAREW and Mrs. BAINBRIDGE, were each accompanied by Awards of Merit. Similar awards were also given to Mr. H. W. GRIGG for a collection of flowering shrubs and herbaceous plants; to Mr. T. MARTIN for Rhododendrons grown on Dartmoor and for Cyclamen; and to Col. HEXT for 20 very fine bunches of double Violets.

The DEVON ROSARY, Torquay (Award of Merit and Silver Medal) staged a fine collection of pot Roses in good bloom. Messrs. R. VEITCH & SON, Exeter (Award of Merit and Silver Medal), showed a miscellaneous collection of plants, among which were noticeable some very fine Amaryllids, winter-flowering Carnations, Clivia miniata, Camellia reticulata, Saxifraga Rhei superba, S. Guildford Seedling, S. coriophylla, S. Griesbachii, Arabis alpina fol. var. Sanguinaria canadensis, Cytisus Beanii, Androsace carnea, A. sempervirens, A. Hendersoni, and Vitis Henryana. Messrs. CUTBUSH & SON (Award of Merit and Silver Medal) showed Erica coccinea minor, Rhododendron Smithii aureum, Iris susiana, I. Haynei, I. pumila, Azalea roseiflora, Primula acaulis cærulea, P. cashemiriana, P. rosea, Boronia heterophylla, Draba aizoon, Daphne Blagayana, and many other plants. Messrs. BARR & SONS (Award of Merit and Silver Medal) provided their usual effective display of the best Daffodils, including Peter Barr.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

APRIL 4.—Committee present: E. Ashworth, Esq. (Chairman); and Messrs. R. Ashworth, Stevens, Cowan, Ashton, Williamson, Duckworth, Parker, Sander, H. H. Smith, Keeling, Leemann, Walmsley, P. Smith, Weathers (hon. sec.).

This meeting proved to be one of the very best meetings since the formation of the society, and the great feature was a unique display staged by Messrs. ARMSTRONG & BROWN, of Tunbridge Wells, whose exhibit consisted of about one hundred and fifty plants of Dendrobium nobile var. virginale, which had been

raised from seed. It was interesting to note the great variety which obtained in this batch of seedlings; of course, all were "albino," but there were great differences in form. The award of a Silver-Gilt Medal was richly deserved.

A. WARBURTON, Esq., Haslingden, again displayed a well-grown collection of plants, to which a Silver Medal was voted.

W. THOMPSON, Esq., Stone, Staffs., gained a similar award for a group, noticeable in which were some extra well-grown plants of Oncidium concolor.

Messrs. J. W. MOORE, LTD., Rawdon, near Leeds, were awarded a Bronze Medal for a miscellaneous group, and Messrs. KEELING & SONS also staged a group for which a Bronze Medal was awarded.

The following awards were made:—FIRST-CLASS CERTIFICATES to Odontoglossum crispum var. Roi d'Angleterre, shown by M. LUCIEN LINDEN; O. crispum-Harryanum x O. x ardentissimum, exhibited by A. WARBURTON, Esq.; O. Bleuanum var. Stevensii, displayed by W. THOMPSON, Esq.; Lycaste x Tunstallii (confirmed), from the gardens of E. ROGERSON, Esq. AWARDS OF MERIT to Odontoglossum Rossii var. magnificum, shown by Messrs. A. J. KEELING & SONS; Dendrobium nobile var. virginale magnificum and Odontoglossum x orphanum, both exhibited by Messrs. ARMSTRONG & BROWN; O. Cervantesii var. decorum, Thompson's variety; O. exultans var. Minerva, both shown by W. THOMPSON, Esq.; O. Sylvia (O. x Rolfeæ x O. cirrhosum), O. amabile var. Grairianum, O. Ossulstoni var. purpurescens, the last three from Messrs. CHARLESWORTH'S nursery. A CULTURAL CERTIFICATE was awarded to a plant of Odontoglossum triumphans var. latiseptum Mrs. Ardern. It was magnificently grown and reflected credit upon the grower, Mr. W. NORRIS. P. W.

Obituary.

J. HILL WHITE.—We regret to record the death from bronchitis of this prominent nurseryman. Deceased was one of the best known nurserymen and seedsmen in Worcestershire, and his services as judge were in frequent requisition at flower shows. As an exhibitor he won many prizes, including the Wolverhampton Challenge Trophy. The late Mr. White was hon. secretary of the old Worcester City and County Horticultural Society for 14 or 15 years. It was principally due to deceased that the Worcester branch of the Gardeners' Royal Benevolent Society was formed, and for several years he acted as branch secretary and treasurer; the subscriptions and monies raised from the throwing open of the grounds of Earl Beauchamp, Mr. C. W. Dyson Perrins, and other gentlemen to the public have resulted in over £1,000 being added to the funds of the society. The funeral took place on Tuesday, the 9th inst., at Astwood Cemetery. The late Mr. White leaves a widow and two sons, Messrs. Harry and Percy G. White, who have assisted him in the business for several years past.

ENQUIRIES AND REPLIES.

WYCH ELM FOR WATER.—I have had some Wych Elm split up, and intend using it to repair banks of rivers. Is this a good wood to last under water? L. L.

ANSWERS TO CORRESPONDENTS.

BLACK CURRANT SHOOT: H. C., Bath. You send no communication with the Currant twig, but if you wish us to say if "big bud" is present or not, we are sorry to inform you it is. For details of the treatment of this pest with lime and sulphur, see p. 221.

CATALOGUES: C. R. We cannot supply copies of the catalogues you mention. Apply to the firms themselves.

CHERRY BRANCH: H. D. W., Edin. The fungus on Cherry branches is Polyporus chioneus. It is not likely that it will attack living trees, as it is not truly a parasite.

GRASS: W. J. M.—One of the best lawn grasses for cultivation in shade is Poa nemoralis.

HOW TO OBTAIN A PATENT: F. B. You must make application to the Board of Trade, Whitehall Gardens, London, S.W. The applicant must file a specification, either complete or provisional, and in either case drawings of the invention may be required. The fee for a provisional protection is £1.

LIMA BEANS: C. W. These are the most appreciated Beans in the United States, but they will not ripen in this country or even in Paris in ordinary seasons. They require a hotter summer climate.

MUSCAT VINE: W. H. We cannot have any knowledge of the cause of the rod failing to grow, unless we were familiar with the cultural conditions, or, at least, had specimens for examination.

NAMES OF PLANTS: G. F. M. Nuttallia cerasifolia.—E. W., Stansted. Forsythia suspensa. The weed is Achillea Millefolium, the common Yarrow or Milfoil, one of the commonest of British plants. Dress the lawn with some nitrogenous manure, such as nitrate of soda mixed with sulphate of potash.—W. B. Oncidium concolor.—C. B. Dendrobium chrysotoxum.—R. O. Y. 1, Stelis muscifera; 2, Masdevallia nidiica; 3, Cochlioda sanguinea.—J. S. D. Bifrenaria tyrianthina, an ally of B. Harrisoniæ, which has cream-white petals and is more commonly seen in gardens.—A. M. G. The Norway maple Acer pseudoplatanus.—J. C., Hampton Wick. 1, Cupressus Lawsoniana; 2, probably the Corsican pine Pinus laricio; 3, probably Pinus excelsa; 4, Thuja occidentalis; 5, Retinospora plumosa of gardens; 6, probably Cedrus atlantica.—W. H. S. Cupressus funebris in the juvenile or Retinospora stage; the Orchid is Cattleya Bowringiana.—Basset. Rhododendron Falconeri.—W. 1, Corydalis tuberosa; 2, Saxifraga crassifolia.—G. H. B. 1, Lonicera tatarica; 2, Sanguinaria canadensis; 3, Anemone blanda; 4, Orobis vernus var.; 5, Orobis vernus var.; 6, Corydalis tuberosa.—Walton. The Rhododendron is one of the hybrids obtained from R. Edgeworthii, and should be cultivated in a greenhouse. We cannot name the varieties of Pelargonium (Geranium).

ODONTOGLOSSUM CRISPUM: A. G. The flower you send has seven perianth-segments, two lips, two columns and two ovaries. There has thus evidently been a fusion of two flowers and some of the segments (of which there should be five in each flower) have been squeezed out in the course of the fusion. Botanists would consider such a flower as an instance of "synanthly." It is not very uncommon.

PEACH FRUITS DOUBLE: Anxious. The formation of two ovaries is a reversion to the ancestral type when five was the normal number. It is not often, however, that the plant "throws back" to the condition of five, but we have often seen cases of two as in yours.

POTATOS: J. McC. The winter-rot, caused by Nectria solani, is the cause of the hollow-ness. This disease always commences in the centre of the Potato, and only reaches the surface when the tubers are not well dried before storing, when sweating occurs.—C. F. C. We cannot determine whether the variety is Up-to-Date. The tubers do not appear to have disease other than ordinary "scab."

ROSA WICHURAIANA: J. C. Rosa Wichuraiana is a "manuscript" name only, that is to say, no botanical description has been given of the plant. Wichura was a German botanist who accompanied a Prussian expedition to China, Japan, &c., in 1859-61. He died of suffocation in Berlin in 1866. See *Kew Bulletin* (1859), p. 300. Bretschneider, *Botanical Discoveries in China* (1898), p. 41. In the *Index Kewensis* R. Wichuraiana is referred to as R. Luciae. Pronounce the word as best you can in English; the foreign pronunciation would be something quite different.

YEW HEDGE: Jas. C. The hedge having been recently planted, it will be as well to defer pruning until June. The stronger growths may be again shortened in September. Somewhat frequent pruning is necessary in order to obtain a satisfactory base in the hedge.

THE EFFECTIVE ARRANGEMENT OF BEDDING PLANTS.*

THE arrangement of colour, in designs of any kind, is to some extent a matter of taste, but there are certain elementary rules generally accepted on the effect of colour arrangement, and these apply equally to the flower garden and to pictures on canvas. Mr. Robinson, in his *English Flower Garden*, observes that the object to follow in a bedded garden is to keep the scheme of colouring as simple as possible, which means, I take it, the avoidance of too great and varied a mixture. Even in the simplest combinations, however, mistakes are often made, probably the most common being a lack of proportion amongst the colours. How often does one see in summer bedding, various shades of red flower and foliage, e.g., red Pelargoniums, Coleus, Iresines, &c., predominating and "drowning" every other colour in the garden. It is often asserted that grey or whitish colours may predominate in summer bedding, even this, when seen in masses of white

variegated Pelargoniums, may become monotonous if used too freely.

Speaking generally, however, the softer and lighter hues should prevail over the bright colours. The latter should also be placed as far away as possible from the principal point of view. If, for example, a path runs around the garden, it is well to have the bright reds, blues, &c., in the central beds, whereas if the walk is in front of the beds, strong colours should be placed at the back, and be so arranged that they graduate into the pinks and other delicate tints in the front beds.

High colours naturally "show up" better, when seen from a distance, than those of softer hue, and if the beds are placed some distance from the house, they should always wear a brighter aspect than those immediately in front of the windows.

To what extent contrast of colour may be allowed in neighbouring beds must always be decided by their distance apart, and by the circumstance whether the intervening space is of grass or gravel. If they are separated by wide stretches of grass, more freedom may be allowed in the choice of colour for each bed than would be the case otherwise, as the bright green of the lawn will tend to tone down contrasts which would be too glaring if the beds were close together or separated by a gravel walk only. A healthy box edging, even, will greatly assist in this direction.

Mr. Cole, in his book, *The Parks and Gardens of London*, says: "The grand principle in the employment of colour is never to place a compound colour between the primitive colours which compose it." Thus, purple ought never to be employed between blue and red, nor orange between yellow and red. On the contrary, purple may often with advantage be placed between yellow and red, or between blue and yellow, or compounds of these colours. On the same principle blue flowers may be placed near orange, as being complementary to the red and yellow composing the orange. These remarks apply to the arrangement of flowers in mixed beds, as well as to their disposition in a parterre. In the latter case each bed forms, or should form, part of the same scheme of colouring, and it is therefore best to confine each quarter to plants of similar hues, only introducing those of other colours to lower or heighten the effects of the main colour, and to aid in making it harmonise with the surrounding beds.

ISOLATED BEDS.

In isolated beds, however, or in beds so widely separated that all cannot be seen in one view, the effect of this is usually very monotonous. In this case, therefore, one should aim at making each bed perfect in itself, by so graduating and mixing the various colours that one should be puzzled to know which tint prevails in the entire arrangement. This requires more skill on the part of the gardener than the arrangement of a parterre of flowers, as the fact of the colours being close together makes any disagreeable contrast the more conspicuous. There should, therefore, be no violent transition from one colour to another, contrasts being as far as possible avoided, in favour of the intermingling and harmonising of many different tints. This applies, as I said before, chiefly to solitary beds in prominent positions,

where they are constantly under observation. For example, a bed of one colour immediately in front of the windows of a residence becomes monotonous before the summer is half over, but a well-arranged, mixed bed shows so great a variety that the eye discovers something new each time it is seen. In more secluded spots, however, and in places where the bed comes suddenly into view, and as suddenly disappears, a mass of one colour is often more effective.

In spring-bedding the duration of the flowers is short, and simpler combinations than in summer bedding may therefore be allowed, as the effects pass away before they have time to become monotonous. Nothing in the way of bedding was more beautiful at Kew last spring than the bed of Spanish Iris intermingled with Gypsophila elegans, on the Range Terrace, although had it lasted for three or four months one might have become tired of it.

So far, I have spoken only of bedding arrangements in regard to colour, and in the style of decoration peculiar to formal or geometrical gardens, that is, of course, the chief consideration.

THE NEUTRAL STYLE OF BEDDING.

Of late years, however, a much freer style of arrangement has been introduced, in which the form and habit of the plant are of equal importance with its colour. Each system has its own peculiar beauty, and, therefore, each should find a place in the garden.

It is generally conceded that the latest development, which I will call the "neutral style," is vastly more effective than the older in certain situations, as, for example, beds on each side of a broad walk. It is, however, equally certain that it will never take the place of the more uniform style in parterres, such as that practised in front of the Palm house at Kew. The chief fault of the older style, as of the parterre generally, is not its regularity so much as its gaudiness.

The increased use of standard plants of Heliotropes, Lantanas, Fuchsias, &c., which relieve, but do not hide, the level surface of the old-fashioned bedding, is reviving some of its old popularity. Of the neutral style there are many gradations from beds filled, more or less thickly, with single plants, or groups of plants of low growth, and of various habits and colours. Such an arrangement differs only from the old-style mixed bed in its less compact appearance. It is most suitable for small beds in restricted areas, and when well carried out is very effective. It also affords opportunities for displaying many plants which may not be required elsewhere.

LARGE BEDS.

In large beds a few of the occupants should be correspondingly tall, for however well a bed may appear when planted, say, with Begonias, or with such a combination as Begonias, Sweet Alyssum, and Lobelias, there can be no doubt that the addition of a few taller plants, such, for example, as Grevillea robusta, is always an improvement. The extra height of the latter plant not only diminishes the apparent extent of the bed, but, in several respects, adds variety to the combination. In this style of bedding one should always remember that one of the most important objects is to produce contrasts of

form. Thus, in the case just mentioned, the introduction of the *Grevillea* creates a pleasing difference between its own foliage and that of the *Begonias*, and, if necessary to create a still more varied effect, this could be attained by alternating the *Grevilleas* with other tall subjects, such as *Fuchsias* or *Acacia lophantha*. The habit of either of these accords well with that of the *Grevillea*, but the plants should be placed sufficiently far apart to allow the form of each to be easily seen and compared with that of its neighbour, for if they be placed too close together, not only is this contrast of form lost, but the lower plants are to a greater extent hidden. The mixing indiscriminately and in heavy masses of tall flowering and foliage plants, and leaving out altogether those of shorter growth, is sometimes practised. In certain situations this plan is to be recommended, such, for example, as in a bed placed near the entrance to a woodland walk, where it is necessary to create a gradual transition from the natural scenery without, to the more formal appearance of the garden within.

In the flower garden itself, however, elegance rather than picturesqueness should be aimed at. It is scarcely necessary to remark that, to produce good results in the "neutral" style, the beds should be placed at a considerable distance apart. Where they are comparatively close together, as at Hampton Court, care should be taken to make each bed distinct in general appearance from its neighbours, whilst at the same time paying due attention to harmony of colour. A. W. Proudlock.

(To be concluded.)

NEW OR NOTEWORTHY PLANTS.

RHODODENDRON INTRICATUM, Franchet.

At the meeting of the Royal Horticultural Society on April 2 Messrs. James Veitch & Sons exhibited a charming little *Rhododendron* under the name of *R. nigro-punctatum* (an account of which is given at p. 225), for which they were awarded a First-Class Certificate. Subsequently Messrs. Veitch presented a plant to Kew, and it was critically examined, with the result that it proved to have been incorrectly named.

In this connection I may mention that previous to his departure for China, a few months ago, Mr. Wilson and I were engaged on a joint examination of the very fine dried collection of *Rhododendrons* made by him on his first and second journeys in China, and presented to Kew by Messrs. Veitch. To facilitate the identification of the numerous species described by the late M. Franchet, Prof. H. Lecomte loaned the whole of the types belonging to the Paris Herbarium to Kew, and we were thereby able to correct some of our earlier determinations. But we were unable to complete our revision and publish the new species, numbering about 25, before Mr. Wilson had to start, and I have not since had time to finish my part of the work, otherwise the species under consideration would, perhaps, not have come before the public under a wrong name.

R. intricatum belongs to the section *Osmothamnus* (genus *Osmothamnus*, DC.), originally founded for *R. fragrans*, Maximowicz, since reduced to *R. Anthopogon*, Don, figured in the *Botanical Magazine*, t. 3947. Maximowicz (Mem. Acad. Imp. Sc., St. Petersburg, 7me. serie, Vol. XVI., 1870, pp. 15-18), added *R. parvifolium*, Adams, and *R. micranthum*, Turczaninow, to *Osmothamnus*, as a section of *Rhododendron*. More recent investigations in

Western China have led to the discovery of upwards of half-a-dozen new species of the same section, all having foliage very similar to that of *R. intricatum*, Franchet (*Journal de Botanique*, vol. IX., p. 395); indeed, so very similar that it is difficult to distinguish them in the dried state. One set has solitary flowers and another clustered flowers; and one set has included stamens and another has exerted stamens.

The flowers of *R. intricatum* are almost invariably in clusters of five; the stamens are included, and much shorter than the corolla; the style is shorter than the stamens, and the

long and densely clothed with small peltate scales on both surfaces. These scales sometimes dry black; hence the name, *nigro-punctatum*, given to one of them.

R. intricatum is quite hardy and flowers profusely when only a few inches high. In a wild state Mr. Wilson found it from 1 to 3 feet high. The flowers are lilac or almost violet in colour, and the yellow anthers just protruding from the tube of the corolla give them the appearance of Violets. When carefully dried they are exactly violet. A coloured figure has been prepared for the "Botanical Magazine." W. Botting Hemsley.

FIG. III.—RHODODENDRON INTRICATUM: FLOWERS PALE LILAC (REAL SIZE), POLLEN-GRAINS MAGN. 240 DIAM.

filaments and inside of the corolla-tube are only very slightly bearded. In *R. nigro-punctatum* the flowers are solitary, terminating the branchlets; the stamens are exerted; the style is as long as the stamens, and the filaments and inside of the corolla-tube are conspicuously bearded. From *R. thymifolium*, Maximowicz, which also has included stamens and a style shorter than the stamens, *R. intricatum* differs in the flowers being clustered, not solitary. *R. blepharocalyx*, *R. fastigiatum*, *R. polycladum*, and *R. polifolium* are other new species, described by Franchet, which are closely allied to *R. intricatum*. All of them are dwarf, densely-branched shrubs having small, oblong, crowded, persistent leaves, mostly under half-an-inch

SUMMER IN BRITISH CENTRAL AFRICA.

(Concluded from page 230.)

A VAST panorama is spread out before one's eyes: apparently one large, white, billowy ocean, dotted with a hundred and one major and minor conical islands; in reality clouds, which are still lying low over the plains, overtopped here and there by the scattered hills. Far in the distance Zomba Mountain is conspicuous, and even more so is the brackish Lake Shirwa, with the hilly Portuguese territory beyond. Turning to the mountain, one is confronted by a series of beautifully-shaped rolling downs, covered with a short grass, with little streams, little lakes, little forests, and little mountains, which, rising

for another 1,000 to 4,000 feet, tower aloft into the clouds. You imagine that the country stretches before you for miles, when, stepping a short distance in another direction, you stop shuddering on the edge of an awful gulf, which, on a misty day, might be taken for the end and edge of the world.

Gradually ascending the grassy downs, they are found to be divided by deep valleys, in which practically all forest growth is confined, the grass land being only broken by shrubby *Proteas* (*P. Nyassæ*), now bearing their large, creamy-white flowers. The top of the downs is reached at about 6,000 feet elevation, and above this lie the numerous ridges and peaks of huge granitic boulders. The vegetation is more pronouncedly that of the Temperate zone. There are large patches of the delightful pink *Erica Johnstonii*, with dense, nodding, globose heads of flowers, which, together with the leaves, have a very woolly appearance, owing to the close aggregation of the tips of the white hairs with which they are fringed; *E. Whyteana*, a smaller plant, with a virgate habit, smooth leaves, and long racemes of delicate pink flowers; *E. arborea*, and the allied *Phillipias*, with numerous minute red flowers. *Vaccinium africanum* is common, and quite a conspicuous figure in the landscape, with its glabrous, ovate, serrated leaves, and numerous axillary racemes of nodding flowers, large, campanulate, white or occasionally red tinged, followed by brightly-coloured, fleshy fruits, the only *Vaccinium* known from tropical Africa.

Hebenstretias, *Selagos*, and *Thesiums* are everywhere. By the lesser streams *Hypericum lanceolatum*, a tree of 20 to 30 feet, is smothered with bright yellow flowers, nearly 2 inches in diameter. Equally showy is *Polygala virgata*, and its forms, growing from 4 to 6 feet high, and bearing graceful pendent racemes of bright purple, rose, and white flowers. *Rubus huillensis* is a very welcome plant, being well furnished with hundreds of luscious, orange-yellow, black-berry-flavoured fruits.

The lower rocky slopes, just above the downs, are spangled with showy *Dissotis*: gay, large-flowered, erect, trailing, and climbing species of *Senecio*; several dwarf, rich blue *Lobelias* and *Wahlenbergias*; thousands of minute *Utricularias*, about 1 inch high, with purplish-blue flowers; *Aloes* and *Crassulas*. Here and there lies a charming bog of sphagnum, accompanied with such appropriate plants as *Drosera ramentacea*, *Lycopodium cernuum*, *Hydrocotyle moschata*, *Tillæa pentandra*, and *T. aquatica*, *Anagallis Quartiniana*, *Cyanotis lanata*, *Ludwigia jussieoides*, *Thalictrum rynchocarpum*, *Anemone Whyteana*, graceful *Carices*, &c. Crowning every rock, in any spot almost devoid of soil, grows the Queen of the Mountains, *Vellozia splendens*, with repeatedly forked stems, chiefly composed of a mass of brown, imbricating scales, crowned with a number of rosulate rigid leaves, from which spring magnificent clusters of large, white, deliciously-scented flowers, now and then tinged with pink. Individual flowers at a casual glance remind one of *Lilium candidum*. Sir Harry Johnston playfully remarks that even the botanists of Kew were momentarily conscious of the plant's beauty, and ere the sensation passed away they named it "splendens." The flowers are produced for many months in succession.

Following the banks of a small stream, along which *Cyathea Dregei* is very common, a glorious shrub in full bloom instantly claims attention. It is *Mussaenda arcuata*, a Rubiaceae subject, with clusters of dainty Primrose-shaped flowers, deep yellow, with a five-rayed star of orange hairs radiating from the tube, with rich, glossy green leaves, and exhaling a delicate perfume. A mental note is made that seeds are to be secured for plant enthusiasts at home. *Podocarpus milanjanus*, with long Yew-like leaves, is very common along the stream-side,

but does not often develop into a useful timber tree as it does in East Africa and Uganda.

Underneath a large *Cyathea* one discovers a fairy scene that only a Shelley at his best could adequately describe. A flat boulder is covered with a dense carpet of a rich green moss (*Funaria hygrometrica*), the almost pellucid leaves spangled with thousands of tiny crystal drops of moisture. Dotted here and there is an Orchid (*Holothrix Johnstonii*) with two roundish ovate leaves closely pressed on to the moss, each plant with a second spike from 5 to 12 inches high, one-third of which bears numerous flowers more delicately pink than "pearls of Eastern fame," and emitting a delicious perfume—dainty pearls set in a bed of countless emerald stars. So exquisite a scene will remain to cheer the mind when now notorious events and personalities are passed into oblivion.

Roaming at ease over the rolling downs, the air is cool and bracing, the sunshine harmless, and one can with impunity discard the helmet so necessary in the plains; but when the sun sets amid indescribable splendours of fiery reds, orange, yellow, pink, purple, black and blue, in what appears to be the middle of the sky—so high is the horizon—when the clouds descend, the lightnings flash, and terrific peals of thunder are echoed and re-echoed from crag to crag, from peak to peak, Nature begins to wear an alarming aspect, and one quickly retires to the cheery comfort and company of a fire of blazing "Cedar logs."

The bracken (*Pteris aquilina*) is common on these downs, greeting one at every turn like a messenger from the homeland. The short grass is studded with *Moræa zambesiaca*, bearing bright purple flowers, equal in size to a fine variety of *Iris xiphoides*; thousands of the intensely blue *Disa hamopetala*, a really blue Orchid, which, for graceful form and charming colour, has no compeer among the *Disas* as yet discovered; *Eulophia Shupangæ*, *Lissochilus milanjanus*, *Gladiolus atropurpureus*, *Mellerii*, *Oatesii*, *oligophlebius*, *Crocasmia aurea*, *Dierama pendula*, *Eucomis zambesiaca*, *Viola abyssinica* and *Ranunculus pinnatus*, all add to a charming display. These will shortly be followed by acres of confusing species of golden and silver *Helichrysums*, tuberous *Crassulas*, other *Gladioli*, *Disas* and *Satyriums*, flaming spikes of *Kniphofias*, snowy-white *Anthericums*, and *Chlorophytums*, *Asters* and *Gerberas*, *Coreopsis*, *Inulas* and *Vernonias*, tall *Leonurus velutina*, with huge whorls of velvety orange flowers, bushes of *Lantana salvifolia*, &c. Clumps of the large golden-yellow, Lupin-like *Argyrolobium shirense* already indicate what a glorious show it can put forth, likewise the very abundant herbaceous *Clematis Kirkii*, a species with erect stems 1 to 3 feet high, bearing from five to 30 snowy-white flowers, each over 2 inches in diameter—two promising plants for greenhouse culture, or even for the open air in the favoured gardens of Cornwall and Ireland, as during the months of July and August these downs are on most mornings covered with a white rime of frost.

THE MLANJE CEDAR.

We turn to the deep, dark, peaceful forests that fill each ravine. Dominating all other trees is the so-called Mlanje Cedar or *Widdringtonia Whyteii*, only known to occur on this isolated mountain. Closely allied to *Callitris*, the older specimens suggest in appearance a combination of the Scotch Pine and the Cedar of Lebanon. The young trees are furnished with Juniper-like leaves, from $\frac{1}{4}$ inch to 1 inch long, green above and glaucous beneath; they are, however, soon succeeded by short, closely-imbricating, scale-like leaves. Grown as an ornamental tree at lower elevations, the Juniper-like foliage is retained much longer; the tree does not, however, remain in a flourishing condition for many years at less than 4,000 feet elevation. As the trees grow above their neighbours, their branches lie horizontally, and point strongly along the

line of the prevailing winds, thus giving them a very flat-topped, one-sided appearance. Most of the branches are profusely decorated with the grey, pendulous Lichen, *Usnea barbata longissima*, which frequently attains a length of 18 inches, and imparts a distinctly Arctic tone to the forests. Trees measuring 3 feet in diameter and 6 feet to the first branch are common, some of the veterans being over 150 feet high and 6 feet in diameter. The bark is extremely thick, the timber faintly red in colour, clean, strong, easily worked, takes a good polish, but has no "pretty" grain, is durable in both wet and dry works, and is especially immune from the ravages of white ants. This last good quality is due to its containing a high percentage of essential oils. In past years hundreds, nay thousands, of fine trees have been destroyed by the bush fires which annually creep up the mountain side; once reaching the oily trees destruction is rapid. This is now prevented by hoeing a broad path around each belt of forest once a year.

Naturally a varied flora is found in these damp, densely-shaded forests. At least a dozen species of *Asplenium* are there, large *Nephrodiums* of great beauty, *Hymenophyllum australe* on tree trunks and damp rocks; also *Gleichenia polypodioides*, *Cheilanthes multifida*, *Pteris quadriaurita*, *Lomaria Boryana*, *Selaginella versicolor*, and *Lycopodium verticillatum*. *Impatiens shirensis*, and others of the Sultani type, are very common. Epiphytic Orchids are all distinctly "botanical species," there being several *Polystachyas*, *Bulbophyllums*, *Angræcums*, *Listrostachys*, and a single *Megaclinium* (*M. Mellerii*). Towards the edge of the forest *Clematis simensis* climbs from tree to tree, with a wealth of bloom that compares well with *Clematis montana* at home. The fragrant Jasmine is represented by *J. stenolobium*. There are also many showy species of *Hibiscus*, *Sida*, *Dombeya*, clumps of *Acalypha villicaulis*, *Clerodendron myricoides*, and many other interesting plants.

The peaceful nature of these forests, the odorous resin, the carpets of emerald-green moss, make one long, when the dews have dispersed, to lie down amid the cooing of the doves and the murmuring cascades and cataracts of the streams, "the world forgetting, by the world forgot."

Spending a few days amid such scenes, living in the foresters' comfortable "log cabin," one returns to Zomba, physically and mentally invigorated, feeling convinced that wherever situated, and whatever difficulties Nature places in one's way, she also provides ample compensation for all who endeavour to investigate and understand her ever-varying, never-ending works. *E. W. Davy, Agricultural, Forestry, and Botanical Department, Zomba, British Central Africa.*

JOHANNESBURG: SUCCESSFUL TRANS-PLANTING OF LARGE TREES IN THE PUBLIC PARKS.

In July last it became necessary, owing to alterations, to remove several large trees in Joubert Park, and as some of these were good specimens, it seemed desirable that an attempt should be made to preserve them. The attempt has been crowned with complete success, as the accompanying photos. (not reproduced) clearly show.

The result has utterly confounded the sceptical critics, who prophesied disaster.

The following is a list of the principal trees:—

Name.	Girth.	App. Height.
	37 in.	30 feet
<i>Fagus Castanea</i> (Chestnut Spanish)	22 "	25 "
	26 "	24 "
	21 "	19 "
	13 "	14 "
<i>Betula alba</i>	8 "	18 "
<i>Quercus Robur</i> (var. <i>pedunculata</i>)	12 " to	17 " to
	24 "	30 "
<i>Cedrus Deodara</i>	—	19 "

As the alterations were unforeseen, none of the trees, with the exception of the Deodar, underwent any preliminary preparation in the way of spring trenching.

The removals were from 20 to 50 yards, and were performed as follows, generally with a running accompaniment of derisive remarks from the aforesaid critics and other bystanders.

The trees were trenched round at a distance of about 2 feet 6 inches and from 3 to 4 feet depth they were under-cut.

All large roots were carefully severed, and the smaller fibrous roots retained. An inclined plane was dug out to the bottom of the trench, and a sledge placed in position, on to which the tree, with its full ball of roots and earth, was gradually shifted by block and tackle. The largest of the Chestnuts must have weighed nearly three tons. The same process reversed was used in planting. After treatment consisted of thinning out and shortening in the heads of the deciduous trees to balance loss of roots, a thorough soaking immediately after planting, and continued at frequent intervals, and repeated sprayings of the bark.

All the trees are living, and are carrying nearly a normal crop of leaves (the Oaks are fruiting); even the Birches and Deodar, usually difficult subjects for transplanting, show scarcely any signs of their removal.

From the foregoing remarks it is evident that, contrary to the general opinion, trees of large size can be successfully transplanted in this Colony during their resting period, provided that sufficient care be exercised in the shifting and continuous attention be given to the watering and spraying, and to this latter I largely attribute our success. *A. H. Stirrat, Superintendent of Parks.*

NURSERY NOTES.

MR. DROST'S NURSERY, RICHMOND.

ALMOST overlooking Kew Gardens, and within a stone's throw of Richmond Station on the S.W.R., is situated the nursery of Mr. K. Drost. This establishment was founded by the late Mr. Herbst, and for the past 23 years has been successfully developed by Mr. Drost.

The nursery is interesting in many ways. For several years it has been recognised by the trade as one of the places where Lilac has always been successfully forced during the winter season; that is, from October till the end of April and May, when the outdoor plants come into bloom. There is an impression that the production of Lilac during the dull season of the year is a troublesome process. In the hands of Mr. Drost, however, there seems to be not the slightest difficulty in securing large quantities of blossom whenever he desires it. The variety he finds most suitable for forcing is known as "rubra de Marly." It has Lilac-blue flowers when grown naturally, but when forced during the winter months, the blossoms become white as driven snow. White varieties, of which "Marie Legraye" is the best, come with a yellowish or creamy hue, and are much more fastidious in their cultural requirements. At the present time Mr. Drost has a grand lot of Lilac in bloom, and a visit to his nursery will well repay a visit.

Besides Lilacs, another of Mr. Drost's specialties is the Hippeastrum or Garden Amaryllis. His plants are in robust health. The bulbs are 5 to 6 inches in diameter, and many of them produce three erect sturdy scapes, on the top of which five to eight flowers of brilliant hues are developed. To give an idea of the vigour of the plants, it may be mentioned that some of the leaves were as much as 5 feet long and 5 inches wide in the middle, while the scapes vary from 2½ to 3 feet high.

Besides the Hippeastrums, the next most striking feature of the nursery, at this season, is the large numbers of Azalea mollis in bloom. Only the finest varieties are grown in large batches as required, and each plant is literally smothered in bloom. Many other interesting items are to be seen, among them being thousands of a bright

Azalea indica—dwarf, sturdy bushes grown in 3½-inch pots and studded with bloom; thousands of Liliun longiflorum and Hydrangea paniculata in all stages of development, while Palms of all kinds, varying from 2 feet to 20 feet high are remarkable for health and cleanliness. To suit the requirements of the trade, they are all grown "hard" in a comparatively low temperature, the result being that they can be transferred from one part of the country to another without risk of catching cold!

Ferns, of course, are grown in vast numbers, and not a trace of disease or pest is to be seen amongst the plants. Each season naturally brings its own peculiar class of plants into prominence, and by and by hundreds of Chrysanthemums will be conspicuous in the nursery. In various stages of development, there are batches of Hydrangea paniculata, which Mr. Drost grows particularly well, and for which he finds a ready sale. *J. W.*

THE ALPINE GARDEN.

GALANTHUS NIVALIS VAR. VIRESCENS.

ALTHOUGH not to be compared in beauty with the ordinary Snowdrop, this variety attracts attention by its quaintness of colouring. It comes into flower a little late, and is much the same in size as an ordinary Snowdrop. It was described by the late Mr. F. W. Burbidge in his paper on Snowdrops read at the Royal Horticultural Society's Conference held on March 10, 1891, and a sketch of the variety, with a description, appears in the *Journal of the Society*, Vol. XIII., Part II., p. 209. The illustration shows the sepals as distinctly striped, and is probably taken from a photograph. Mr. James Allen, at the same Conference, describes it thus: "G. virescens is a very singular-looking flower, reminding one somewhat of an Ornithogalum. The outer petals are pale green, shading off to pure white at the edges, and especially at the tips; the inner petals are entirely green."

This is in accord with the flower as I know it, and one can entirely agree with the subsequent remark by Mr. Allen, that: "At first I did not care for this variety, but it has a quiet beauty which grows on one, and I should not now like to lose it."

It was grown by Dr. Fenzl, the late director of the Vienna Botanical Gardens, who sent two bulbs to Herr Max Leichtlin, and afterwards one was sent to Rev. Harpur Crewe and one to Mr. Allen, whence the stock in British gardens has sprung.

GALANTHUS VIRESCENS (DOUBLE-FLOWED FORM).

I AM giving the double green-flowered Snowdrop this name with great hesitation, as it is very unlike the single one, and cannot, in my opinion, have sprung from it. I have known of its existence for a few years, having first heard of it from Mr. W. B. Boyd, of Faldonside, Melrose, who is most diligent in finding out the rarest Snowdrops, and to whom we owe the discovery of some of our most distinct forms. It is, I believe, derived from an old Scottish garden. In the autumn of 1905 I had the good fortune to become possessed of a bulb, but it did not produce an inflorescence last spring. This year, however, it is not only giving promise of increase, but it has also given me one flower, and is the most singular-looking of all the Snowdrops I know. The floral segments, of nearly the same length, are practically all green, the shade being a darker one than that of the single G. virescens. The segments are very long and narrow, and slightly shaded; but the carriage of the flower is also singular, being semi-upright, and the whole appearance of the plant reminds one of what we should expect to find in a miniature form of Fritillaria citrina with double flowers, but semi-erect, and darker in colour. The leaves are of a dull green. Probably G. viridiflorus fl. pl. would be a more correct name. *S. Arnott.*

TREES AND SHRUBS.

LONICERA MAACKII (See fig. 112, p. 25).

AT one of the recent meetings of the R.H.S., Messrs. Paul and Son, of Cheshunt, showed specimens of this hardy Honeysuckle, which attracted attention by reason of its slender, arching branches with nearly glabrous, ovate, acuminate leaves and dense clusters of creamy-white flowers. Mr. Worthington Smith's drawing well shows the characters of the plant: with the lower lip of the corolla four-lobed and the relatively large pollen grains. These are nearly globular, finely ciliated and with three furrows.

The plant was originally called Xylosteum Maackii by Ruprecht, but as Xylosteum is now considered a section of Lonicera, the name above given is the one to be adopted. The fullest description, accompanied by a coloured plate, is given by Maximowicz in the *Garten Flora* (1884), tab. 1,162.

The species is a native of Southern Manchuria and Northern Japan. Fortune is also stated to have met with the plant in Northern China, so that there is no reason to doubt its hardiness in Britain. It flowered first in cultivation in the St. Petersburg Botanic Garden in 1883, so that it can by no means be considered as a new plant in gardens, though it is not so widely distributed as its merits entitle it to be.

The synonymy of the species may thus be given LONICERA MAACKII—Herder in *Bull. Soc. Imp. Nat., Moscow*, xxxvii (1864), p. 204, tab. 2, fig. 4; Maximowicz in *Garten Flora* (1884), tab. 1,162; and in *Mel. Biol.* x., 67. *Xylosteum Maackii*, Ruprecht in *Bull. Phys. Math. xv.*, 369; Maximowicz, *Primit. Flor., Amur*. 138.

THE PROPAGATOR.

As the sap ascends in increasing volume in this month, it is a favourable time for the propagation by cuttings of various species of plants.

CENTAUREA CANDIDISSIMA.

In view of the intended propagation of this plant in the month of July, old stock plants showing for bloom should have the flower buds removed, which will have the effect of inducing numerous lateral shoots to form, which, half-stripped from the base and left hanging by a bit of the rind for a week, or longer time, so as to get healed, will be available as cuttings in that month.

SALVIA SPLENDENS AND ITS VARIETIES, AND S. GESNERIIFLORA.

Cuttings of these plants may now be taken from plants previously cut back, and hastened into growth in gentle heat. The cuttings root easily in a mild bottom heat in sandy loam, having a layer of sand on the surface. They should be removed to a cooler atmosphere as soon as sufficient roots have formed.

RHODODENDRON (AZALEA) INDICUM.

Growing shoots can at this season be used as cuttings, striking them in porous, elastic soil (peat and loam, two-thirds of the former to one-third of the latter, and some sharp sand added), a mixture to be preferred to sand alone, in which the cuttings are apt to die off from lack of nutrition when not at once potted off. It is advisable to put a thin layer of sand on the soil in the cutting pans or pots. No bottom heat is required, merely a regular warmth of about 50° Fahr.; therefore, a bed with a northern aspect is best, and in such they may stand over the winter. The lower leaves, so far as the cuttings enter the soil, should be cut off. Until rooting takes place, they must be covered with bell

glasses having a hole at the top; or, if a case is employed, it must be ventilated occasionally. Cuttings of *Menziesias*, *Rhododendrons*, *Kalmia*, and *Rhodora* may be rooted in the same manner.

BAMBUSA, ARUNDO, AND SIMILAR GRAMINEÆ.

The rhizomes of these plants, if cut into pieces consisting of two joints and laid in a mixture of peat and garden soil on a warm bed of tree leaves and stable litter, and finally covered with a $\frac{1}{2}$ -inch layer of soil, soon push growths. The frame lights should not be more than 3 to 4 inches distant from the bed, and the temperature of the

state which may be found at this season, and at others, according to species and position and aspect, will serve as cuttings. It is advantageous to cut through about one-third of their diameter those shoots which are selected for the cuttings about 14 days previously to taking them. By so doing, a callus forms, which is all to the good of the cutting. If the shoots are very soft, a heel of the old wood should be taken with it. The soil which is employed in the pots should contain a large quantity of sharp sand. The cuttings should be afforded a bottom heat of 60° to 68° Fahr., and top heat of 50° to 55°, and the soil kept in a regular state as regards

mould, placed in an atmosphere of 60° to 65° Fahr., and bottom heat 10° to 12° higher.

AUSTRALASIAN ACACIAS.—The various species can be struck from cuttings at this season and also in the autumn; the cuttings should be of medium consistency—1 to 2 inches in length, and taken off close to the older wood. To strike them, a temperature of 55° to 50° is required, but no bottom heat, and a rather abundant supply of water. The lower leaves should be removed from the cuttings. These species may be struck, if they have simple leaves, from root cuttings, cutting back the hair-like roots and setting the pieces in pots of sandy soil, so that the ends are

FIG. 112.—*LONICERA MAACKII*, HARDY SHRUB: FLOWERS CREAMY-WHITE.

bed must remain at 65° to 75° Fahr. Under the influence of this amount of warmth and moderate applications of water, shoots soon appear at the nodes, which quickly push forth roots at the base, and may then be removed, together with a small bit of the rhizome, and potted, placing them in a warm bed to develop. Those pieces which have not pushed shoots may be returned to the bed of soil, so as to compel the remaining nodes to break.

LEGUMINOUS PLANTS.

In general, the young shoots in the half-ripe

moisture, and for that reason cutting pans should be used 2 inches more in diameter than the bell glasses that cover them, and the water should be applied outside the latter. The more suitable glasses are those with a hole at the top. These remarks apply chiefly to the cool-house species, those of the stove requiring more warmth.

ERYTHRINA.—The young shoots which at this season form at the neck of the root stock should be removed, together with the swollen base, and inserted singly in pots of sandy loam and leaf-

visible, and covering them with bell glasses. In the same manner *Bouvardias*, *Plumbago rosea*, *Clerodendrons fragrans* and *Bungei*, *Passifloras*, *Theophrasta*, *Aralia papyrifera*, and *Wigandia caracasana* may be struck. The tropical species may be struck from well-developed shoots as soon as growth has begun. They require a temperature of 65°, and bottom heat of 75° to 80° Fahr.

MYRTUS, CALLISTEMON, AND MELALEUCA, &c.—Cuttings of these species may be rooted in the present month in dung-beds covered with frames, and if many cuttings are to be struck, a bed of

sandy peat soil and two parts sand answers as well as pots. The cuttings should be divested of their leaves to one-third of their length, and inserted to that depth. If pots be employed, the mixture is the same, and the drainage should consist of a layer of crocks 2 inches in depth. A moderate bottom heat and top heat of 50° to 55° Fahr. are necessary. Of Eucalyptus, choose as cuttings shoots found on old stems and furnished with a swelling. Those species with but little powder or wax on the leaves, and which have hard leaves, must receive much moisture; *E. cordata*, *E. perfoliata*, and *E. pulverulenta*, a lesser quantity. *F. M.*

THE ROSARY.

NEW ROSES OF BRITISH ORIGIN.

SEVERAL new varieties of merit have recently been sent out by Messrs. Wm. Paul & Sons, of Waltham Cross. Of these, one of the most attractive by reason of its brightness is *Warrior*, a new scarlet-crimson Hybrid Tea. The buds are of blood-red colour, and the variety somewhat resembles the beautiful *Papa Gontier* in its characteristics. *Celia*, also raised by this firm, is a highly decorative and extremely floriferous Rose; so much so, that disbudding is advisable if large flowers are required for exhibition purposes. *Dora* is a Hybrid Tea of exquisite form; the colour is of the shade termed "silvery blush."

Amongst the more notable Roses recently introduced by the Irish Rosarians, Messrs. Alex. Dickson, of Newtownards, may be mentioned the variety *Lena*, a garden hybrid of unique beauty (it is figured in the firm's autumn catalogue); the colour is a rich shade of apricot, with a delicate suggestion of primrose at the edges of the petals as the flowers expand. Mrs. G. W. Kershaw, of strong, vigorous habit and free-flowering tendencies, with large, impressive rose-pink blooms; and Mrs. Myles Kennedy, a creamy-white Rose of quite unique grace and distinction, with buff and pink suffusions, described by the raisers, not without expressiveness, as "a glorified *Souvenir d'Elise Vardon*." This variety was given the Gold Medal of the National Rose Society. Mrs. Peter Blair, a grandly decorative Rose, endowed with splendid foliage; and William Shean, a pure pink variety with flowers of grand dimensions, have also been raised by the Newtownards firm, who have likewise recently given us the beautiful *Lady Rossmore*, with blooms of a beautiful crimson that is shaded with claret. It was raised by Dr. J. Campbell Hall.

To Mr. Hugh Dickson, of the Belmont Nurseries, Belfast, whose finest seedling, so far, is *J. B. Clark*, we are indebted for *Lady Overton*, with petals of a pale salmon colour, shading to silvery pink; and Mrs. A. M. Kirker, pure bright cerise, a Rose of great value for garden decoration. Both of these are Hybrid Perpetuals, a class that has of late years been somewhat neglected in favour of the more delicately coloured Hybrid Teas, which, drawing many of their most fascinating attributes from the Tea varieties, are generally supposed to be more graceful in form and in aspect more refined. Not a few varieties of merit have of late years been sent out by Messrs. George Paul & Sons, of Cheshunt; prominent among these is *Nellie Johnstone*, of exceedingly bright and luminous colour, with long, pointed buds and petals of the purest pink colouring, with tender violet modification on their outsides. The blooms are fragrant. It is a supposed cross between *Madame Berkeley* and *Catherine Mermet*. *Richmond* is a most interesting derivative from the variety named after *Lady Battersea*. Two Roses from Colchester are also acquisitions. These are *Nance Christy*, raised by Messrs. B. R. Cant & Sons, and named after one of the heroines of Mr. S. R. Crockett, the famous novelist. The plant is of vigorous growth, and the flowers are salmon-pink in shade and semi-double. The other is Mrs. O. G. Orpen, a climbing Rose of great attractiveness, of lustrous, roseate hue. *David R. Williamson*.

The Week's Work.

THE FLOWER GARDEN.

By A. C. BARTLETT, Gardener to Mrs. Ford, Pencarrow, Cornwall.

Window boxes.—Two sets of boxes, one for summer and another for winter use, are more economical and convenient than when the same boxes have to do duty all the year round. If duplicate boxes are available, the summer boxes may now be furnished, after which they should be placed in a cool house for a week or two to partially establish the plants before they are placed in the windows, about the middle of May. At this date no danger from frost need be feared, as the heat radiated from the walls will protect the plants at night-time. The compost used in the boxes should be rich, and should contain sufficient plant-food to last the season, for window boxes cannot be surfaced with manures nor soaked with liquid manure. A good general mixture consists of fibrous loam, with the addition of leaf-mould, bone-meal, and sand. Place a few crocks in the bottom of the box as practicable, rather using as drainage a layer of coarse broken loam. Plant firmly. The selection of plants will, of course, depend upon the owner's taste, but if possible the boxes should be furnished with something different from the ubiquitous white *Marguerites* and pink ivy-leaved *Pelargoniums*, which, while forming a pretty combination, lack distinctness, and on repetition becomes wearisome. To many people occasional plants of *Heliotropes*; *Lippia citriodora*, and scented-leaved *Pelargoniums* of the less perfumed class, are acceptable in a window box. For a north window such plants as *Begonias*, *Calceolarias*, *Fuchsias*, and *Pansies* are recommended.

Zinnias.—Seeds of this annual should now be sown. Place the seed-boxes in a gentle bottom heat, and as soon as the seedlings are large enough to be handled, transplant them singly. When these plants are rooted do not subject them to a high temperature.

Campanulas.—Sow in moderate heat seeds of both the blue and white varieties of *C. pyramidalis* in pans of light soil. Last year's seedlings which were planted in nursery beds are now throwing up their flower-spikes. The present is a suitable time to lift and plant *Campanulas* in small groups in the herbaceous borders, and also in large beds of miscellaneous plants in the flower garden.

Annuals.—Seeds of Sweet Peas and other flowering plants should be sown in the open ground to provide a succession to the first sowings.

Hardy Bamboos may be planted at any time during the next few weeks. Shelter from winds is essential, an ideal spot being a gentle slope, and, if possible, one bordering a stream which has a good background of dark foliage to act as a foil to the lighter plumes of the Bamboos. As the roots of Bamboos are excessively brittle they should be disturbed as little as possible when planting, and it will be better to smash the pot than to force the plant from it. The young shoots also share this brittle character, and where game or rabbits abound it will be wise to place some wire-netting around the choicer varieties for a time.

FRUITS UNDER GLASS.

By ALEXANDER KIRK, Gardener to J. Thomson Paton, Esq., Norwood, Alloa, Clackmannanshire.

Pines.—The earliest fruits will now be colouring, they will therefore require a dry atmosphere, and very little moisture at their roots; watering must be discontinued entirely ere the fruits become quite ripe. Plants that are coming in flower and those that have just passed that stage in the same pit should not be grown in too moist an atmosphere, but it will be necessary to damp the paths twice daily, and to ventilate freely in order to keep the plants sturdy. The night temperature should be regulated to 75° or 80° Fahr., and the structure should be closed in the afternoon with the inside temperature at 90° Fahr. Maintain a steady bottom heat of 80°. Wherever the plants that have gone out of flower require moisture at their roots, give warm manure water.

Pines which are growing actively in 8-inch pots should now be shifted into other receptacles 2 or 3 inches larger. After potting, plunge the plants in a bottom heat of 85°, and keep the atmosphere close and moist for a few

days, and lightly spray the plants occasionally with the syringe.

Strawberries should be cautiously forced now. As soon as the fruits are all gathered from the earliest batch, remove the plants to a cold frame, where they may become hardened ready for planting outside. Other batches that are swelling their fruits should be given warm manure water twice a week. Thin the fruits on each plant to eight or ten. Syringe the plants early in the day with hot water; this will help to keep down attacks of red spider, for this pest and green fly must never be allowed on the plants. Remove the latest batch of plants into a cool Peach house; these will furnish fruits up to the time the outside crop is ready. Should the plants be attacked with mildew dip them in a solution of potassium sulphide, using 1 ounce of the chemical to a pail of warm water. The variety *Royal Sovereign* is very subject to attack by mildew, but this remedy will prove effective. It should be done before the plants are in flower.

Figs in pots or in borders.—Trees on which the fruits are swelling will require to be well supplied with tepid manure water. Some growths must be cut out and others pinched at the fourth leaf and, in the case of the wall trees, tied or nailed to the trellis or wall. Syringe on each afternoon and keep the atmosphere of the house moist during the whole of the daytime. Close the structure early in the afternoon, and reduce the quantity of atmospheric moisture as soon as the fruits begin to ripen.

Cucumbers should have a night temperature of 70° to 75° Fahr. Close the pit with an inside temperature of 90°, and keep the house moist always, as Cucumbers dislike a dry atmosphere at any time. Give plenty of water at their roots, alternated occasionally with manure water. Top-dress and mulch the ridges with spent manure from a mushroom-bed. Syringe freely, especially if red spider or thrip make their appearance, and shade the plants from bright sunshine. Sow for a successional batch.

Early Grapes in pots, which have ripened fruits in bearing, will now require a cool, dry atmosphere and a plentiful supply of ventilation both by day and by night-time. Afford water very carefully and do not allow them to become excessively dry. Treat these vines in pots in much the same manner as that recommended for early vineries in last week's calendar.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower to Sir Trevor Lawrence, Bart., Burford, Surrey.

Odontoglossum crispum.—On receiving newly-imported plants of this popular Orchid, the grower should carefully examine them, and cut away all dead and diseased parts. A stage in a shady part of the coolest house should be set aside for them, and upon the stage should be placed a thin layer of rough peat mixed with sphagnum-moss. Place the pseudo-bulbs upon this compost, and, if possible, in an upright position, but first damp the moss and peat with a fine syringe. No further moisture will be required for some considerable time, as that derived from the usual daily damping of the house will generally suffice until growth actively commences. If only a small consignment has been purchased, every piece of growth that will form a plant should be separately potted in as small a receptacle as can conveniently be used, filling up to and around the base of the plant with small crocks, and making the plant as firm as possible. At Burford we twist a thin piece of well-dried Fern rhizome around the rhizome of the Orchid, place the plant in the pot, allowing the ends of the rhizome to reach the bottom, and then pack crocks closely around for the purpose of steadying the plant, and keeping it in its proper position. Stand the pots on a moist bed, and pour water through the crocks occasionally to assist the pseudo-bulbs to regain their plumpness. In due time the new shoots will appear, and fresh roots form at the base, when the plants should be potted in well-drained pots and with only a thin layer of moss and peat pressed moderately firm on the surface. After potting, afford gentle waterings, but as the new growths gain strength, moisture may be more frequently and liberally afforded.

Old and well-established plants of *Odontoglossum crispum*, also its congeneric species and hybrids are in various stages of growth. Many are sending up strong flower-spikes, and these

plants will require plenty of water at their roots until after the inflorescences have been cut, when the quantity of water afforded should be only sufficient to keep the pseudo-bulbs in a fairly plump condition.

Afford plenty of atmospheric moisture to plants in the cool house, especially in those houses which are naturally dry, and admit as much fresh air as possible whenever the weather will permit. Shade the plants from the direct rays of the sun, and afford a minimum amount of fire-heat, unless the nights become very cold. As the season advances, artificial heat should be dispensed with, unless a morning frost is apparent, when the valves should be turned on when retiring for the night, for the temperature should not drop below 50° and 55°. Turn the valves off again the first thing in the morning, and throughout the day, when the external air is at a temperature of about 40°, the bottom ventilators should be slightly opened, and when it has risen to 45° more air should be admitted, and at 50° a little top ventilation should be afforded, increasing it in accordance with the outside temperature. On dull, cold days, maintain a temperature ranging between 55° and 60°.

THE HARDY FRUIT GARDEN.

By J. MAYNE, Gardener to the Hon. MARK ROLLE, Bickton, East Devon.

Strawberry beds.—A month having elapsed since the manure was forked into the ground between the plants, it will now be time to lay down clean straw for the fruits to rest upon later, but before doing this work, the flat hoe should be drawn up the rows when the ground is dry enough. The recent rains have improved the appearance of the Strawberry beds, and a mulching of straw applied now will preserve much of the moisture in the soil for some weeks. The littering of Strawberry beds is better done ere the flower-spikes are advanced, for there is always a danger of crippling many of these. Long, strawy litter from the stable yard is often used, but the manure is liable to affect the flavour of the fruits, and many employers object to its use. There is nothing better than clean oat or barley straw, as these are pliant, and can be quickly laid around each plant. After the fruit has been gathered, the straw can be removed and mixed with stable manure. It is advisable to scatter a layer of fresh soot around each plant before the straw is applied, for the purpose of warding off slugs. Pinch out the flowers of the perpetual bearing kinds.

Raspberries.—Suckers thrown up far from the parent plant should be cut up with the flat hoe, raked off, and wheeled to the rubbish heap. Perhaps of all our hardy fruits, the one under notice thrives best when given a cool, moist rootrun; the plants will therefore benefit by a thick mulching of partly-decayed manure spread evenly a yard in width either side of the canes.

Insect pests.—The Plum is one of the first trees to be attacked by insects, the curled growths, and oftentimes withered shoots being an indication that an insect is present. Upon unfolding the damaged leaves, a tiny worm or maggot will be found, and this should be destroyed by squeezing between the finger and thumb.

THE KITCHEN GARDEN.

By WILLIAM H. HONESS, Gardener to C. COMBE, Esq., Cobham Park, Surrey.

Peas that were planted from pots, &c., as advised early in the month, will be ready for sticking, and, if possible, a mulching of stable litter should be applied at the same time. These mulchings cannot be too strongly recommended, and are especially valuable throughout the summer, particularly on soils of a light texture, and in dry seasons. Batches that were sown in the winter or early in the New Year in cold houses and frames will now be in full flower, and in some instances the pods will be setting. Continue to make fresh sowings fortnightly, and although Peas give good results if sown in drills, by far the better plan is to sow them in trenches as previously explained, a system that proves its value in seasons when watering has to be largely resorted to.

Vegetable Marrows.—The main sowing should now be made: the more forward of the seedlings can be placed under handlights and cold frames for furnishing early fruits, and the remainder planted later in the open, where they must be given some temporary protection for the first fortnight or so.

Cardoons on heavy land succeed well if planted

on the flat and without trenches. Three seeds should be placed in a four-inch pot, and the seedlings eventually thinned to the strongest plant. As soon as large enough, plant in rows 3 feet 6 inches apart. On light soil Cardoons are best grown in trenches prepared as for Celery. This plant is not so generally grown as it should be, for it provides a welcome addition to the commoner vegetables.

Winter vegetables, such as Borecoles, Broccoli, Savoy, &c., should now be sown in shallow drills in a seed bed. A space of 12 inches between the rows should be allowed, but if it is intended to transplant them before their final planting, then a distance of 6 inches will be sufficient. In some gardens, these form the whole of the winter green vegetables, but the list can be added to by the inclusion of the newer Kales, such as Improved Hearting, Hardy Sprouting, and Chou de Russie.

PLANTS UNDER GLASS.

By J. G. WESTON, Gardener to H. J. KING, Esq., Eastwell Park, Kent.

Winter-flowering Begonias are almost indispensable subjects in gardens. *B. Gloire de Lorraine* may be had in bloom at almost any season of the year, but as a general rule it is most welcome in the autumn and winter months. It is one of the easiest plants to propagate, and its cultivation presents no difficulties. If flowering plants are required for next autumn and winter, the cuttings should now be inserted,

FIG. 113.—BEGONIA GLOIRE DE SCEAUX.

around the sides of a 60-size pot filled with light sandy soil. Place the cuttings in the propagating frame, where they will quickly form roots, after which they should be given less heat, and later be potted singly, in a compost of equal parts of turfy loam and leaf-soil, with plenty of sand added. A shelf in a warm house is a suitable place for staging the young plants, which must be shaded from strong sunshine, syringing the plants freely night and morning, and generally maintaining a moist atmosphere in the house in which they are growing. The white variety *Turnford Hall* makes a pleasing companion plant to the red variety. Among other varieties of winter-flowering Begonias *B. nitida* and *B. n. alba* are persistent bloomers, and a batch of these plants made a fine show in these gardens throughout the past winter. *B. nitida* does well either grown in pots or planted out. The flowering shoots are effective when trained on wires or pillars.

Begonia Gloire de Sceaux (fig. 113) is another useful winter-flowering plant, the bronzy, metallic sheen on the leaves contrasting well with the rose-pink of the flowers. Grown under ordinary conditions, this variety is at its best in spring, but where its growth can be hastened in the summer it flowers in mid-winter, when its value is greatly enhanced. It is also a good

plant for indoor decoration, the warm, dry atmosphere in such situations suiting it when in flower. Cuttings should be inserted at once, and the plants grown without a check all through the season. Watch for *Begonia-rust*, and also for a very small thrip, which, if left unchecked, will quite cripple the growth of the plants; a spraying with some safe insecticide is the best preventive.

Other valuable additions are the hybrids from *B. socotrana* and the tuberous Begonias, of which Ensign, John Heal, Mrs. Heal, and Winter Perfection are examples.

PUBLIC PARKS AND GARDENS.

By W. W. PETTIGREW, Superintendent of the Parks and Open Spaces in the City of Cardiff.

Meteorological instruments in public parks.—As meteorological conditions have such an all-important bearing upon horticulture, it is but natural that gardeners should take a very practical interest in the subject, and have a few meteorological instruments placed in some more or less suitable position in the garden under their charge. This, coupled with the fact that long experience enables most gardeners to detect those subtle alterations in atmospheric conditions which usually indicate a change in the weather, leads to gardeners being regarded by the general public—rightly or wrongly, as the case may be—as authorities upon most matters meteorological.

Interest to the public.—Apart from the bearing that this subject has upon horticulture, it has also much interest for the public, and for this reason one park in every town of importance should be furnished with a collection of standard meteorological instruments, the records of which should be available at all times for inspection. The collection of instruments in a public garden has, as a rule, a double advantage over those often found in private gardening establishments. In the latter case, unless the owner of the garden is himself an enthusiast, the collection is generally of a very modest character, consisting merely of a rain gauge, maximum and minimum thermometer, the first of which is perhaps the only one of the three instruments that gives a correct record. In a public park station the instruments are not only more numerous and diverse in character, but by being tested periodically at Kew, their readings can be thoroughly relied upon. The records from apparatus of this description are not merely of passing interest to ordinary observers, but are of permanent value for future comparisons.

Local value of records.—For several years past the Parks and the Health Departments of Cardiff have established a collection of meteorological instruments in one of the parks under their control, from which day by day records of the meteorological conditions obtaining in the immediate district have been supplied to the citizens by the aid of the local Press. Two years ago the Meteorological Office recognised this as a climatological station, and in this way it has become of more than local importance. At the present time the collection of instruments consists of a maximum thermometer, minimum thermometer, dry-bulb and wet-bulb thermometer—all four enclosed in a Stevenson screen, a grass minimum thermometer, which indicates terrestrial radiation, two earth thermometers, and a rain gauge. As the Cardiff Naturalists' Society is about to present the Corporation with a barometer, a sunshine recorder, and black-bulb and bright-bulb thermometers, the collection will soon be a fairly complete one and of considerable value to persons interested in meteorology.

Chart board.—In order to enable visitors to have the records of the various instruments day by day, a chart (to be marked each morning at 9 o'clock) will in future be exposed on a board specially prepared for the purpose and placed in close proximity to the site where the readings are taken.

Position for the instruments.—The position for a climatological station must be carefully selected. It should be in the open, and away from trees or other shelter, and, if possible, on flat ground. Care has to be taken when fixing a Stevenson screen that it is so placed that the instruments contained in it are exactly 4 feet above the ground level and facing due north. The black and bright-bulb thermometers—used to record solar radiation—require to be fixed horizontally on a stand 4 feet above the ground, but with their bulbs facing due south.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Special Notice to Correspondents.—The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.

Illustrations.—The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but he cannot be responsible for loss or injury.

APPOINTMENTS FOR THE ENSUING MONTH.

TUESDAY, APRIL 30—

Roy. Hort. Soc. Coms. meet and Nat. Auricula Soc. combined Show in R.H.S. Hall.
British Gardeners' Assoc. Ex. Council meet.

WEDNESDAY, MAY 1—

Nat. Auricula and Primula Soc. Sh. (Midland Section) at Birmingham Bot. Gardens.
Croydon and Dist. Spring Fl. Sh.

THURSDAY, MAY 2—

Linnean Soc. meet.
Manchester and North of England Orchid Soc. meet.

SATURDAY, MAY 4—

Dresden International Hort. Exh. (May 4-12).
Soc. Franç. d'Hort. de Londres meet.
German Gardeners' Soc. meet.

TUESDAY, MAY 7—

Mannheim International Exh. of Orchids (3 days).
Scottish Hort. Assoc. meet.
Nat. Amateur Gard. Soc. meet.

WEDNESDAY, MAY 8—

Roy. Caledonian Hort. Soc. Sh., Edinburgh (2 days).

TUESDAY, MAY 14—Roy. Hort. Soc. Coms. meet.

SATURDAY, MAY 18—German Gardeners' Soc. meet.

MONDAY, MAY 20—Bank Holiday.

WEDNESDAY, MAY 22—

Devon County Agricultural Sh. at Bideford (3 days).
Roy. Bot. Soc. and Nat. Tulip Soc. Exh., Botanic Gardens, Regents Park.

FRIDAY, MAY 24—

Linnean Soc. Anniversary meet, 8 p.m.
Roy. Bot. Soc. meet.

MONDAY, MAY 27—

Annual meeting and dinner of the Kew Guild at the Holborn Restaurant.

TUESDAY, MAY 28—

Roy. Hort. Soc. Sh. in the Temple Gardens, Thames Embankment (3 days).

WEDNESDAY, MAY 29—

Ann. meeting British Gardeners' Assoc.

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich—49°2'.

ACTUAL TEMPERATURES:—

LONDON.—Wednesday, April 24 (6 P.M.): Max. 78°; Min. 53°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—Thursday, April 25 (10 A.M.): Bar., 30°2; Temp., 61°; Weather—Overcast.

PROVINCES.—Wednesday, April 24 (6 P.M.): Max. 67° Ipswich; Min. 51°, Scotland, N.

SALES FOR THE ENSUING WEEK.

WEDNESDAY—

Border Plants, Hardy Bulbs, Palms, &c., at 12; Lilliums in cases and miscellaneous Bulbs at 5; at 67 & 68 Cheapside, E.C., by Protheroe & Morris.

FRIDAY—

Imported and Established Orchids in variety from various growers; Orchids in flower and bud, at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.45.

case this past year or two in some of the great fruit-growing districts that growers are complaining that these varieties are scarcely profitable to grow, and so far they see no sign of any new varieties to take their place. Not one of the newer sorts introduced since the two varieties mentioned were raised are of better use for profitable culture, the general fault being that the fruits are too soft to travel the shortest distance to market. In the big fruit-growing district of the eastern counties, covering parts of Cambridgeshire, West Norfolk, and South Lincolnshire, and including the Wisbech district where thousands of acres of Strawberries are grown, not a single acre of any other kind but these two can be met with. But the plantations, especially during the past two years, have become very weak in growth, and barrenness is on the increase, the weight of fruit per acre not being, at most, two-thirds the crop of some few years back and the individual fruits are not as large nor of such luscious quality. Even when the plants used in the making of new plantations are obtained from maiden plants and are not allowed to fruit until the second year (when they should be at their best) the produce is still inferior to that of former years, both in weight and in quality. Mildew is also more prevalent, especially in the case of Royal Sovereign, and during last season some plantations were utterly ruined by this pest. Barren stools are also much more frequently met with.

Many of these troubles may, perhaps, be attributed to the growers themselves as the consequence of bad and careless cultivation, &c. Runners for new plantations are frequently obtained from old and worn-out stools, in some cases as much as five years old, and no attempt at selection is made. In the majority of cases mildew is allowed to attack the whole field before any means are used for checking the fungus. There is little doubt but that both Royal Sovereign and Sir Joseph Paxton would have been as good as ever to-day had the growers practised selection when making new plantations. In the absence of new varieties to supersede these kinds there is a great need for some trade grower to make a speciality of selecting and re-selecting runners from stools that show improved qualities. To commence with, runners should be procured from maiden plants; that is, those that are one season planted from the runners and which have not yet fruited. Again, runners should be taken from plants which show extra vigour in foliage and which have developed the largest and finest quality fruits. The first plants on the runners only should be utilised, or, at most, not more than the second ones, and none should be taken that develop later than about August 1. They should be layered into 8-inch pots and immediately the pot is full of roots the plants should be detached from its parent and planted into its permanent quarters, for it is a mistake and a cause of barrenness to allow the runners to remain connected with the old plants until they become pot-bound. Should it not be convenient to practise the potting system, runners may be planted direct from the beds, but with somewhat less success. The same system of selection and pinching, as when pots are used, should be employed, and in no case should the planting be undertaken later than the end of September or the beginning of October, otherwise frost and wet will cripple the plants before they secure a good root-hold. To carry the system of selection still further, it would be necessary to watch closely for stools in any plantation, and no matter of what age, that show a decided advance in cropping qualities, colour of fruits, or other improvement. Such stools should be marked with a stake and be given exceptional treatment with a view to selecting the runners. If methods such as are described above be regularly adopted there would be less cause for complaint in varieties deteriorating, but on the contrary an improvement would be seen. As every cultivated plant is greatly

stimulated by a change of soil and situation, it would be of value if growers arranged with other cultivators a hundred miles or so away to exchange annually a certain quantity of Strawberry plants for stock purposes."

OUR SUPPLEMENTARY ILLUSTRATION.—It would seem as if the process of "improvement" could no further go in the matter of the florists' Hippeastrum. In the magnificent strains exhibited by Major HOLFORD, Messrs. VEITCH & SONS, and Messrs. KER, of Liverpool, we seem, as far as number of flowers, their size, form, and colour are concerned, to have reached a stage when, however much variety in colour may be obtained, yet but little novelty can be expected. It is, therefore, desirable that new blood be introduced so as to extend the limits of variation. To this end Dr. BONAVIA has been experimenting by crossing H. 'pardinum' with an ordinary florists' Hippeastrum. The result is illustrated in our supplementary plate, and is decidedly promising. The colour is white profusely spotted with carmine. Even the midribs of the perianth-segments are profusely spotted. The spike bore four flowers and was produced before the leaves. Several seedlings were raised from the same cross, but this was the most heavily spotted.

ROYAL HORTICULTURAL SOCIETY.—The next exhibition of flowers and fruits will be held in the Hall at Vincent Square, Westminster, on Tuesday, April 30, in conjunction with the National Auricula Society's annual show. In the afternoon a lecture on "The Amateur, and Horticultural Law" will be delivered by Mr. H. MORGAN VEITCH.

SEED TESTING.—Whilst each of our large firms has its own seed-testing department, it is somewhat singular that there should be such a deficiency of public seed-testing stations here as compared with the Continent. The station at Tharandt, in Saxony, has a wide reputation, that at Zurich, under the charge of Dr. STEBLER, is equally well known. At Hamburg there is a Versuchstation und Samenprüfungs Anstalt. There are several in Sweden, one in Vienna, and a large number in the United States. We might mention others, but we have said enough to show our own defect in this particular. The Royal Agricultural Society has, for nearly forty years, done its best to satisfy the requirements of its members, its laboratory having been conducted by Mr. CARRUTHERS, and much useful work has been done for farmers' associations and even for foreign Governments. Mr. CARRUTHERS, in association with Mr. HANS GUSSOW, now proposes to extend his operations, and we can but wish him and his associate every success, and recommend those who require information about the purity and germinating power of seeds, or about plant-diseases in general, to avail themselves of the assistance of the gentlemen we have mentioned. To extensive knowledge they add prolonged experience, so that those who apply to the London Botanical Laboratory and Seed Testing Station, 44, Central Hill, Norwood, may be sure that they will obtain, at moderate expense, trained assistance from those highly qualified to give it. Much information of this kind is given weekly in our columns, entailing on us much trouble, expense and loss of time for which no direct return is obtained or even expected. If some of this work, however, is taken off from us, we shall be left the more free to attend to the more legitimate duties of journalism. The tariff of fees asked by Messrs. CARRUTHERS and Gussow is fixed very low and in some instances too low, as in the case of the "determination of a weed or other plant with report on its qualities and the means for its extermination," or where "a report on a disease affecting the plants of the farm, garden, orchard or forest" is desired. For

Deterioration in Strawberries. The following letter in respect to alleged deterioration in varieties of Strawberries is sent us by a correspondent.

"It is now becoming plainly apparent that there is an urgent need for new varieties of market Strawberries, both for early and for late cropping, and superior, if possible, to both Royal Sovereign and Sir Joseph Paxton when they were first introduced. For some years past, and particularly during the past two years, both the once magnificent Royal Sovereign and Sir Joseph Paxton, the standard early and late varieties respectively, have shown unmistakable signs of deterioration and loss of stamina. So much has this been felt to be the

HIPPEASTRUM "QUEEN OF SPOTS," RAISED BY DR. BONAVIA, FROM A CROSS BETWEEN
A SHOW VARIETY AND H. PARDINUM.

uch services as these, demanding as they do, enerally, considerable expenditure of time, and ended as they are by highly trained and competent authorities, the fees asked appear to us disproportionately small. Professional services such as these should either be rendered gratuitously, or, if remunerated, the remuneration should be adequate.

LINNEAN SOCIETY.—Mr. W. CARRUTHERS, F.R.S., formerly president of the Linnean Society, will attend at the celebration at Upsala of the 100th anniversary of the birth of LINNÆUS as the representative of the society. Mr. B. DAYDON JACKSON, as we formerly mentioned, will also attend the meeting.

—The next general meeting of the society will be held at 8 p.m. on Thursday, May 2, 1907. Papers:—(1) Prof. E. B. POULTON, F.R.S., F.L.S., "The Fauna and Flora of Abyssinia compared with those of West Africa;" (2) Mr. CYRIL CROSSLAND, M.A., "Report on the Marine Biology of the Sudanese Red Sea" (communicated with an introduction by the president); (3) "Formation of the Shone Cliff near Alexandria;" (4) "Recent History of the Coral Reefs of the North-west Shores of the Red Sea;" (5) Mr. E. R. SYKES, F.L.S., "Polyplacophora collected by Mr. Cyril Crossland;" (6) Mr. C. J. WITHE, "On Chelonethi (Pseudoscorpions) from Asia and Australia" (communicated by the Rev. T. R. R. STEBBING, F.R.S., F.L.S.); (7) Mr. A. B. DARBISHIRE, "Note on the Function of the Spiracle in certain Elasmobranchs" (communicated by Prof. A. DENDY, Sec. L.S.). Exhibition:—(1) Prof. E. B. BULTON, "Probate of the Will of Richard Anthony Salisbury," and (2) "Manuscripts of Dr. W. J. Burchell, F.L.S.," presented to the University of Oxford by Francis A. Burchell, Esq., Rhodes University College, Grahamstown, grand-nephew of the great naturalist and explorer.

R.H.S. EXAMINATION FOR PUBLIC PARKS' EMPLOYEES.—The results of the second examination held by the Royal Horticultural Society of the employees in public parks have now been published. Of the 59 candidates who entered, 51 have passed, 3 in the first class, 17 in the second, and 31 in the third. These figures show a considerable advance over those obtained in 1906, when the numbers were 6 in the first class, 11 in the second class, and 26 in the third class respectively, making a total of 43 out of 90 who entered. Of the 59 candidates who sat at the last examination, 56 were in the employment of the London County Council, and of these 48 passed, 3 in the first class, 17 in the second, and 28 in the third. Apart from the educational value of these examinations, the actual pecuniary advantages are considerable. In the parks service of the London County Council, the under gardeners who are successful in this examination are classed as gardeners, and receive an immediate increase in their wages of 1s. a week, with a possibility of obtaining two further increments of the same value each year, or a maximum of 30s. if they are placed in the first or second class. As the higher posts in the Council's parks are filled by promotion from the lower ranks, the obtaining of such a qualification is very important, especially as, when considering the claims of candidates for promotion, due regard is had to the possession of certificates in practical horticulture. Moreover, in filling up vacancies on the permanent staff, preference is given to those applicants who have passed the examination of the Royal Horticultural Society.

"KEW" SEEDS.—The "Kew Seed Company, Kew Gardens, Kew," must not be confounded with the Royal Botanic Gardens, Kew. No seeds are sold by the last-named establishment.

NATIONAL AURICULA AND PRIMULA SOCIETY (Southern Section).—The annual exhibition of this society will be held at the Hall of the Royal Horticultural Society, Vincent Square, Westminster, on Tuesday, April 30. The secretary is Mr. T. E. HENWOOD, 16, Hamilton Road, Reading.

BEAUTIFUL GARDENS.—A book with this title has been published by Mr. WALTER P. WRIGHT [Cassell & Co., Ltd.]. Beautiful gardens, how to make and maintain them, are subjects well understood by Mr. WRIGHT, who adds practical experience to good taste, and is sure of an ever-eager band of readers. Beginning with the ideal garden, towards making which all enthusiasts work, we are led to consider gardens that are beautiful and the features that tend to make them so. Lastly, and most at length, are chapters each devoted to one kind of plants (as Roses, Phloxes, &c.), and it is here that most practical hints are given. Fruit and vegetables are not forgotten, and there is a timely "Garden Remembrancer." In "A Garden Year" Mr. WRIGHT introduces some dialogues between three persons who, between them, aim at forming a beautiful garden. The book is illustrated and has an index.

AMERICAN GOOSEBERRY-MILDEW.—The following memorandum with reference to the American Gooseberry-mildew (*Sphaerotheca mors-uvæ*) has been issued by the Board of Agriculture and Fisheries:—"During the winter of 1906-7 the presence of the American Gooseberry-mildew in certain gardens in Worcestershire has been definitely confirmed, and the cases investigated under the auspices of the Worcestershire County Council. The reports which have been sent to the Board of Agriculture and Fisheries show that the extent and seriousness of the disease are much greater than was at first supposed, and, in view of the increased danger of infection which arises when the mildew passes into its summer stage, the Board think it desirable to issue a further warning to all fruit-growers, nurserymen, gardeners, and other growers of Gooseberries. No reports of the presence of the disease elsewhere than in Worcestershire and Gloucestershire have been confirmed, but as it is abundantly clear that the mildew has been present in certain centres in these counties for three or four years, and has spread to many adjoining gardens, among which must be included some nursery gardens, it is only too probable that it will be found in other districts as the spring advances. All Gooseberry-growers are, therefore, advised to watch the plants closely during the summer months, especially those bushes which have been recently bought, in order that the disease may be detected and dealt with at the earliest possible moment. The evidence that has been collected in Worcestershire shows that in most cases it is only the young shoots that have been attacked, and that generally, though not always, the disease has appeared in low-lying, damp situations. The attention of Gooseberry growers should, therefore, be directed chiefly to the damper places and to the young wood. All Gooseberry-growers who have the least reason to suspect infection are advised to spray their bushes with a solution of liver of sulphur (potassium sulphide) from the time the leaves open until the fruit is set. A solution of half an ounce to a gallon and a half of water is recommended for the first spraying, and the strength should be increased to a solution of half an ounce to one gallon of water at the second spraying. In some climates it has been found that spraying with half an ounce to the gallon of water has injured the leaves of the Gooseberry. Growers should, therefore, carefully note the effects of the first spraying, and

if the leaves appear to have suffered any injury from the weak solution, the stronger solution should not be used. On the other hand, if a spray of half an ounce to the gallon does no harm, the grower may resort to somewhat stronger spray fluids. The spray should be applied at intervals of from 14 to 20 days. It must be understood, however, that the liver of sulphur spray is recommended as a preventive, and that it cannot be relied upon to produce a cure. Should any suspicious symptoms be discovered on the plants, in spite of these precautions, the case should at once be reported to the Board. A few slips of bushes showing the disease in its most marked form should be cut off and sent carefully packed in a strong wooden or metal box (not a cardboard box) with the report to the Board. The postage on letters and packages sent by letter post need not be prepaid. All other suspected shoots should be cut off and destroyed at once. Care should be taken to see that the light conidial spores on the bushes are not distributed by the wind to other plants, and the knife or shears used in cutting off the slips should be disinfected immediately afterwards by dipping in the spray fluid. The Board will inform the correspondent as soon as possible if the plants are affected with the American Gooseberry-mildew, and if so he should take immediate steps to prevent the disease spreading. The best means to be adopted will vary in different cases. The following are suggestions for guidance:—Growers must remember that during the summer months the spores which spread the infection are very readily carried from plant to plant. They should, therefore, aim (1) at getting rid of all infected material as soon as possible; (2) at destroying all leaves, buds, and fruit to which it is at all probable that infection has spread. In dealing with small bushes the best plan would be to prune off the branches one by one, to drop them into a pail, and then to destroy by fire or by steeping in a cask containing a solution of four ounces bluestone (copper sulphate) or two ounces liver of sulphur to the gallon of water. In the case of large bushes, it would usually be best to prune off all the young shoots and then to destroy the leaves on the lower part of the bush by employing a spray containing eight ounces bluestone to the gallon of water. It would not be safe to attempt to cut down or dig out affected bushes during the summer, for in doing so workmen would probably spread the disease. Having disposed of all diseased material and of the leaves, buds, and fruit on all plants to which infection may have spread, the grower should next spray the whole plantation with a solution of half an ounce of liver of sulphur to one gallon of water. He should repeat the spraying within a week, and continue it at intervals of 10 days throughout the rest of the season. Spraying should be done on a dry day; if rain should fall soon after spraying, and the liver of sulphur is washed off, the bushes should be sprayed again as soon as they are dry. In order to assist growers in identifying the disease the Board are issuing an illustrated leaflet, which will be sent upon application. American Gooseberry-mildew has attacked Red Currants in Ireland and some other countries, and there is reason to believe that it may also attack Black Currants and Raspberries; these plants should, therefore, be kept under observation by fruit-growers. The Board would again urge upon growers the necessity of taking every possible precaution to prevent the spread of American Gooseberry-mildew during the summer months. From the experience of Irish and Continental growers it would seem likely that those owners of affected Gooseberry bushes who neglect to take drastic measures may incur serious losses. T. H. Elliott, Secretary."

BRITISH GARDENERS' ASSOCIATION.—We are informed that at the last meeting of the Executive Council of the British Gardeners' Association, Mr. R. HOOPER PEARSON in the chair, 18 new members, including three apprentices, were elected, bringing the total up to 1,051. The Secretary read the draft report to be submitted at the annual meeting. The Secretary was instructed to invite, through Mr. GEO. SCHNEIDER, the French gardeners who will visit London in May to attend the annual meeting of the Association. The Secretary undertook to find out the cost of a circular trip to the Continent during the summer. The report of the proceedings of the Publication Committee was read. It was decided that only advertisements of an educational character be published in the *Journal of the British Gardeners' Association*, and these only on the cover. On the motion of Mr. DALLIMORE, seconded by Mr. FULTON, it was decided that the list of members and report of the Executive Council be printed together for circulation, and be kept separate from the *Journal*.

GARDEN CHANGES.—The extraordinary calamity that has overtaken the WIGAN family, by which it has lost two succeeding Baronets in little more than a month, has its sequel in the announced sale of Orchids from Clare Lawn, East Sheen. The late Sir FREDERICK WIGAN, Bt., had a collection of which any amateur might feel proud, and his Phalaenopsis were probably unequalled in this country. His Orchid-grower, Mr. W. H. YOUNG, who had charge of the Kew Orchids 18 years ago before succeeding Mr. WANT as Orchid-grower to Sir FREDERICK WIGAN, has written the "Orchid Calendar" in this journal for several years, and is generally esteemed as a first-class cultivator. We are informed that he will now be free to take up another situation as Orchid-grower, or as gardener and Orchid-grower, and we hope that he will soon find a suitable field for the exercise of his ability.

THE OUTLOOK IN THE VALE OF EVESHAM.

THE appearance of the Vale of Evesham at the present time is exceedingly promising, but it is never safe to prophesy as to a fruit season until June. In past years we have seen a glorious promise absolutely spoilt by frosts in the latter part of April and in May, and it may be so again. The Plum trees are now in full bloom, and it is a hopeful sign that the leaf has appeared with the bloom. This will no doubt prove a protection should the much-dreaded frosts occur. The trees look exceedingly healthy. It was thought when the cold weather succeeded the prolonged drought that the blossom would be later than last year, but the summer-like weather at Easter made a great difference to the appearance of the country, and the trees advanced very rapidly. The few warm days have been succeeded by a continuance of cold north-easterly winds, and it is feared that these may have a deleterious effect on the flow of the sap, the effect of which will be seen when the stoning process commences. Fortunately, there have been no frosts to speak of at present. The Gooseberry bushes look very healthy, despite the fact that in some plantations the American Gooseberry-mildew was discovered in the autumn. In this matter the Worcestershire County Council, who had the assistance of the Board of Agriculture, took prompt action, but in the absence of powers of compensation, they were able to do little except in the matter of advice. It was unfortunate that two such authorities as Mr. Salmon and Mr. Massee, both of whom visited the affected districts, should have disagreed as to the seriousness of the outbreak and the remedies to be applied, as this led to an amount of apathy which is to be deplored.

Developments of this disease are awaited with interest. Red spider has already made its appearance among the Gooseberries, and various washes are being used to check its ravages. The Apple trees look exceedingly healthy, and the buds are just ready to burst. The Apple-sucker (*Psylla*), which has become a very serious pest, are beginning to hatch out, and we shall soon know the results of the various washes which were experimented with by the Fruit-Pests Committee during the winter. It will be remembered that this committee did a very fine work in counteracting the activity of the winter moth, which practically destroyed the Plum crop some years ago, and it is a very satisfactory sign of the times that the committee has been resuscitated. The Strawberry plants look very strong and healthy. Gardeners have had a bad spring so far, and money has been short. The Radish crop has been very much of a failure, as two sowings were general, and now the yield is short but the price is well maintained. Onions are selling well, but Spring Cabbages, an important crop in this district, are late, and are coming in badly. Many are running to seed. The welcome rain of last week has improved them, but warmer weather is needed if they are to head up well. Asparagus is just coming in, and is

one instance, though soil and aspect appeared identical in both cases. Around Penzance a heavy fall of snow, to the depth of a foot, was experienced. This did considerable damage, the limbs of many Conifers being badly broken, whilst the finest specimens of *Ozothamnus rosmarinifolius* in the south-west was beaten to the ground, necessitating it being cut hard back. Frost of an intensity of from 10° to 16° Fahr. was registered in this district, but probably more damage was done in exposed gardens by a bitter easterly gale which raged for days during the continuance of the frost. In one garden all the plants of *Echium*, *Mesembryanthemum*, *Arctotis*, and *Gazania* (10 varieties) were killed, as were *Myoporum laetum* (a plant 18 feet in height, the largest specimen in the south-west), *Meryta Sinclairi*, *Acacia armata*, *A. longifolia*, *A. lophantha*, *A. verticillata*, *Pittosporum undulatum*, *Brachyglottis repanda* in flower-bud, clumps of *Iris* (Morea) *Robinsoniana*, 6 feet high, *Cantua dependens*, *Solanum jasminoides*, *Candollea tetrandra*, *Psoralea pinnata*, a fine specimen in another garden, 10 feet high, being also killed. *Metrosideros* (true), not the *Callistemon* that is usually sold under this name, has nowhere been injured. Other plants killed or badly hurt are *Hoheria populnea*, *Furcraea*

FIG. 114.—SHOWING THE WHITEWASHED FRUIT TREES, WITH THE POET'S NARCISSUS GROWING BETWEEN THEM, AT EVESHAM.

meeting with a ready sale. There will be no bulk in the market until the conditions change. Flowers, of which more are grown every year, are late, but are now coming in. Wallflowers sell poorly, and the Narcissus were too late for the Easter festival, and consequently have suffered in price. They will be at their best at the end of this week. We are able to give a photograph of a field of these flowers beneath Plum trees in full bloom, and this is an example of what may be seen by the acre in the Vale H., April 15.

EFFECTS OF THE WINTER IN THE SOUTH-WEST.

I HAVE just returned from a tour of gardens in southern Cornwall, where I carefully studied the effects of the past winter. The more one examines the eccentricities of the frost the more inexplicable do they appear. In one garden a plant is killed that in another place is uninjured, and vice versa. This I noticed in more than

longæva, *Buddleia madagascarensis*, still alive in two other gardens against walls; *Semele androgyna*, so badly cut that its recovery appears problematical, and *Calceolaria Burbidgei*, which is dead in all cases except one that came under my inspection. In the garden under notice, several species of *Correa* and the New Zealand *Aralia crassifolia* were unhurt, whilst *Lomatia ferruginea* also came through the winter unharmed without protection. In other gardens in the neighbourhood of Penzance the following losses occurred: *Thibaudia acuminata*, *Lagerstroemia indica*, *Fuchsia triphylla*, *F. Dominiana*, *Euryops virginicus*, *Solanum Wendlandi*, *Eriostemon pulchellus*, *Lonicera Hildebrandiana*, *Phoenocoma prolifera*, *Brachysema acuminata*, *Leschenaultia biloba major*, *Sutherlandia frutescens*, *Dendromecon rigidum*, *Sparmannia africana*, *Tecoma jasminoides*, *Cestrum aurantiacum*, *Leonotis Leonurus*, and *Lasiandra macrantha*, though in one garden this was breaking again freely. The vicinity of Falmouth did not suffer as severely as that about Penzance,

and in a noted garden in the former town Myoporum laetum was scarcely injured, but Solanum aviculare, 15 feet in height, was killed, as was Acacia lophantha, and Datura sanguinea, 14 feet in height and 24 feet through (the largest specimen known) was dead to the ground level, but it will doubtless break again from the root stock. A fine plant of Sempervivum holochrysum was badly injured, and but a small piece is alive.

TREMOUGH.

At Tremough, Rhododendrons grafted the preceding year lost some of their lower leaves, but the young leaves at the top of the shoots were unharmed. Other losses around Falmouth were large plants of Sollya heterophylla, Swainsonia alba, Grevillea Preissi, G. pendula and Cape Heaths. The garden that had suffered least of all those that I visited was Trebah. This is situated in a sheltered valley running down to Helford River and is about 8 miles from Falmouth. On the house an Ivy-leaved Pelargonium was alive, but every other plant of this flower that I saw, excepting one on some Government buildings close to the water at Falmouth, was dead. The Zonal Pelargonium is evidently hardier, for a plant that had reached the eaves of a small house in a street in the outskirts of Penzance was apparently uninjured, and I saw others that were scarcely damaged. Tacsonia quitensis and T. mollissima were shooting again from their bases. Three fine plants of Psoralea pinnata, about 7 feet in height, were absolutely unharmed, not a leaf being browned, and only the upper foliage of a large bush of Loropetalum chinense, 4 feet in height and 6 feet through, was harmed; an Echium was also uninjured, this being the only one I saw that was not killed. A specimen of the Cape Silver Tree (Leucadendron argenteum), 7 feet in height, which has been planted in the open for six years, had its foliage a little cut, but was not seriously hurt. Metrosideros robusta and M. lucida were both killed, as they were in all gardens in which they were growing, and a fine tree of Acacia lophantha, 15 feet in height and 18 feet in spread, was dead, but a young plant in a sheltered spot was alive and green. Young plants of Solanum aviculare were also alive, though the finest specimen was killed; Grevillea robusta, Libonia floribunda, and Dimorphotheca Ecklonis were unharmed. Greenhouse Rhododendrons, of which there are enormous bushes in the open, had not a leaf injured, but the greatest proof of the exceptionally favourable conditions at Trebah were the Tree Ferns, which, although standing in the open with no protecting branches overhead, had perfectly green fronds, whereas in other gardens the leaves were quite brown.

PLYMOUTH.

In the neighbourhood of Plymouth the frost was more severe, and shrubby Veronicas were killed. Calceolaria integrifolia was cut to the ground, but is breaking strongly from the base.

The past winter has certainly been the most disastrous experienced in the south-west for many years. In my garden, at the mouth of the Dart, Sollya heterophylla, Semele androgyna, Bowkeria triphylla, Mandevilla suaveolens, Lonicera Hildebrandtiana, and Salvia dichroa are uninjured. Iris Robinsoniana, Salvia leucantha, and Arctotis aureola have been badly damaged, but the two last-named are breaking from the root-stock, and Iris Robinsoniana, after the dead leaves were cut away, showed green beneath, and will doubtless recover. Arctotis aspera arborescens is dead, as is Psoralea pinnata and an unprotected plant of Lagunaria Patersoni, but another that was protected has survived. Myoporum laetum is badly hurt, but alive, and M. rosmarinifolium is dead, as are Solanum aviculare and Gazania longiscapa. Nowhere in Cornwall have Embotrium coccineum or Clethra arborea been damaged, and Clanthus puniceus has, only here and there, been slightly cut. S. W. Fitzherbert.

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

THE EMPLOYEES OF THE SEED AND NURSERY TRADE OF THE UNITED KINGDOM.—How many there may be I do not know, but the number must be considerable. With the exception of a few associations in such centres as Edinburgh and Dublin, there is no organisation of a widely-spread character to which an employee, however isolated, might belong, and through which, if need be, he might express his opinions. Gardeners have societies scattered up and down the country, and unquestionably these bodies have done much to stimulate and spread a wider and deeper knowledge of the things of that profession. The seed and nursery trade has its association and its various journals, but it must be admitted that often the employee, unless he holds a substantial position, is debarred from seeing these publications, and, further, his interests are but little catered for in any one of them. The question has long been in my mind and probably in that of not a few others, whether it would be desirable and feasible to form an association of the seed- and nursery-trade employees of the United Kingdom. I believe that employers generally would view such an association with favour and encouragement, as tending to foster a larger interest in their work, and as helping to develop what latent talent many employees may possess. It will be at once seen that such an association would be of little practical value if there were no means of bringing the members into continual touch with each other, and this would probably be best achieved by a journal issued at regular intervals, in which topics of general interest should appear, grievances could be aired, discussions carried on, and information disseminated. Such a paper might possibly be further utilised as a means of assisting members in various ways. It is not my purpose, however, neither is this the occasion, to attempt to plan out the full possible operations of such a journal or association, but to solicit the opinion of my fellow-assistants on the question: "Whether an association of employees is desirable and feasible." The Editor is in possession of my name and address, and in the meantime some of my colleagues might favour him with their opinions. *Seedsman*. [Seedsman's assistants are qualified to become members of the British Gardeners' Association, and that body is about to bring out a journal to fulfil the very objects to which our correspondent refers. The Secretary is Mr. J. Weathers, 7, Talbot Road, Isleworth, with whom "Seedsman" should put himself in communication.—ED.]

ROSA WICHURAIANA is not merely a manuscript name, as stated on page 260 of your last issue. It was fully and carefully described by Crépin twenty years ago in the *Bulletin* of the Belgian Botanical Society, Vol. XXV., part 2, page 189. It was also described and figured in Sargent's *Garden and Forest* for 1890, plate 477, and under the name of *R. Luciae*, by Sir J. D. Hooker in *Bot. Mag.*, t. 7421. J. G. Baker. [We took our statement from the *Index Kewensis*.—ED.]

LEAD ARSENATE AS A SPRAY.—The season is approaching when fruit growers will be spraying their trees for caterpillar, and they may be glad to know that arrangements have now been made whereby the American preparation, known as Swift's arsenate paste, will be procurable from English dealers in insecticides. Those who make their own lead arsenate by mixing solutions of sodium arsenate and lead acetate may be reminded that the proper proportions are $\frac{3}{4}$ of acetate to every one of arsenate, if the latter be what is sold as "dry" or "crude" arsenate, or else, two of acetate to one of arsenate, if the latter is the crystallised or "pure" salt. Smaller proportions of lead acetate may result in serious scorching; larger proportions may cause some scorching, and must cause waste of money. For every 450 ounces of the wash, 1 oz. of the crystallised, or $\frac{1}{4}$ oz. of the "dry" sodium arsenate, is the maximum proportion which should be used. The proportions in which the two substances should be mixed depends solely on the nature of the chemical reaction occurring, and this action has now been fully established (6th Woburn Report, 1906, and *Transac-*

tions Chemical Society, March, 1907): yet the Board of Agriculture continues to recommend in their leaflets (one of them just recently issued) proportions which have been proved to be incorrect, hurtful, and wasteful, which are opposed to those accepted everywhere else (even by their own chemical adviser), and of which they themselves can give no explanation. *Spencer Pickering*.

POLLINATION OF DAFFODILS.—All who have worked at crossing Narcissi must have noticed the very early maturity of the stigma, and found that in order to utilise it at its most receptive stage, the safest plan is to open the flower while still in bud. Working under glass early in the season I used to wonder why this was so, seeing that the anthers begin to shed their pollen almost immediately after the flower opens: in other words, the female stage of the flower adapted for cross-fertilisation seemed to last too short a time, self-fertilisation becoming imminent almost as soon as the perianth segments unfold. Later, when the same varieties of Daffodils such as Horsfieldii, Sir Watkin, and Barrii conspicuus were blooming out of doors in their own season, the secret was revealed. Every bud I opened at a certain stage in order to extract the stamens contained several tiny flies apparently very much at home and not anxious to escape. Not being a naturalist I cannot speak with authority about these flies or their habits, but it seems obvious that if they were first attracted to a wide open flower in its second flowering period when they would get dusted by the pollen, and then crept into the lightly-folded opening buds, where I found them, they would effect naturally and accidentally that cross-pollination which occurs naturally and which gardeners attempt with design. I found no flies in very young buds, nor in those opening a few weeks before their natural season under glass. J. Garner.

CYDONIA JAPONICA ROSEA.—Amongst these well-known members of the Pyrus genus, to some of which have been given the apposite name of "Fire-bush," none, so far as I have seen, give such a brilliant mass of bloom colour as this variety, judging from two plants of it growing against a low east wall at Hampton Court Palace. Visitors walking down the footpath in the inner gardens leading to the vinery may have seen a mass of rich colouring that on reaching has proved to be produced by those two plants. Kept close to the wall by nailing and pruning, the mass of large Chery-red flowers produced have been so great as to literally cover wood and leafage. Others in the same garden, white, red and pink, are pretty, but for the production of a wonderful mass of colour, these plants of the variety rosea are much the more effective. It is all the more remarkable, seeing that the plants get little sunshine after mid-day. D.

PHOTINIA SERRULATA.—No injury has occurred to the young growths of this shrub in these gardens, but scarcely any of the flowers have opened, for they were nipped by the frost. Our specimen is a very good one and measures 118 feet in circumference, and about 20 feet in height. It is growing in the open, but receives some protection on the north and east sides. Not only is the young foliage very pretty, but the old leaves often have a brilliant scarlet colouring before falling. We registered 15° and 16° of frost several times this winter. G. H. Head, Kingsdon, Taunton.

PLANTS SUITABLE FOR A DRY BANK.—A dry bank is not found in every garden, but those who possess one are often interested to know what may be grown upon it. In the late Sir Michael Foster's garden at Shelford a bank is furnished with some early spring flowers. Vinca minor first attracts attention, and in consequence of its dry position the stems are quite short and the flowers appear fully in view as if they were those of a Gentian. On the same bank near by Phlox subulata, often known as P. frondosa, is very charming. The best effect is obtained by Aubrietia in contrast with Alyssum saxatile. The purple of the former mingled with the gold of the latter makes a perfect combination of colours. Anemone Pulsatilla and its immediate allies are, of course, quite at home, and for numerous Irises of the bearded section this situation is perfectly suitable. The various kinds of Dianthus suggested here by a plant coming into flower must not be forgotten. R. Stewart Lynch.

PYRUS SORBUS.—With reference to the opinion expressed in an article in the *Gardeners' Chronicle* for April 18, where it is said (p. 238), "We doubt if the liquor so obtained would be very acceptable to anyone at the present day," you will be interested to know that here, in Anjou, we cultivate the Service tree, which grows wild in our forests, for the sake of its wood, which is used by turners and cabinet-makers, as well as for its fruit. We utilise the fruit in three ways: 1, from the juice of the fresh fruits extracted by the press we make excellent cider superior in taste and alcoholic strength to perry; unfortunately the juice is not abundant; 2, from fresh fruits put into a cask with water and allowed to ferment, we make a beverage much appreciated by the country folk, who contrive to make it keep a very long time, adding water from time to time above as they draw off the liquor below; 3, the fruits dried in an oven and stored dry are useful when fermented in water to make a palatable drink analogous to that made with dried Apples. *R. Chollet, Cheffes, Maine et Loire, France.*

PELARGONIUM SPORT.—I am sending two trusses of Pelargonium bloom. No. 1 is a sport from No. 2 and you will observe they are very distinct, the sport being a double and pale pink, similar to Madame Crousse, Ivy-leaf Pelargonium. I have five plants of the sport that I propagated and they are all coming true. The truss I am sending is the first truss fully out, but if you care for any more, when there are more out, I shall be pleased to forward them. *J. S., Liphook.* [The sport is a very interesting one, not only are the flowers doubled by the replacement of the stamens by petals, but they are perfectly regular in form and the petals are devoid of the dark blotch characteristic of the petals of a show Pelargonium. A botanist would say that the flowers were instances of "regular peloria" and "petaloidy of the stamens."—ED.]

SOCIETIES.

ROYAL HORTICULTURAL Scientific Committee.

APRIL 18.—Present: Dr. M. T. Masters, F.R.S. (in the chair); Sir John Llewelyn, Bart., Messrs. Curtis, Hooper, Douglas, Cuthbertson, Druery, Elwes, Bennett-Poë, Bowles, Baker, Güssow, and Chittenden (hon. sec.).

Green wood.—Rev. W. WILKS exhibited a dead branch having the wood of a deep verdigris green colour. All the fallen branches in a certain wood in Sussex became of this green colour. Such wood is used in making "Tunbridge ware," and owes its colour to the presence of a fungus, *Chlorosplenium æruginosum*.

Plants exhibited.—A species of *Megaclinium*, with the curiously flattened rachis, was shown by J. B. H. GOODDEN, Esq., F.R.H.S., of Sherborne, Dorset; another Orchid, under the name of the "beetle" Orchid of Australia, with flowers curiously simulating a beetle with long antennæ, shown by Mrs. WHITLAW, of Amerden, Taplow, and an interesting bigeneric hybrid between *Diacrium bicornutum* and *Epidendrum Ellisi*, with flowers of a pinkish colour, shown by J. COLMAN, Esq., of Gatton Park. The terrestrial Orchid, *Satyrion coriifolium* (*Bot. Mag.*, tab. 2172), was shown by Messrs. WARE. It has a long spike of yellow flowers, having the labellum at the upper part of the flower, since the ovary is not twisted as in most Orchids. A vote of thanks was unanimously proffered to the exhibitors.

***Tchihatchewia isatidea* (Boiss).**—The Viscountess EMLYN, Frensham Hall, Haslemere, exhibited this very curious Cruciferous plant, a native of the mountains of Asia Minor, where it grows at an altitude of between 5,000 and 6,000 feet. The habit of the plant is exactly that of an *Echium*. A Botanical Certificate was unanimously awarded to the plant. (Figured in *Bot. Mag.*, tab. 7608).

New break in Auricula.—Mr. DOUGLAS showed an Alpine Auricula having golden stripes running through the edges of the petals. Mr. DOUGLAS stated that this was the first time he had seen this remarkable variation in colour.

African Crinums.—Mr. ELWES showed inflorescences of Crinums, one having white flowers with a very curious and somewhat un-

pleasant scent, which Mr. WORSLEY recognised as a form of *Crinum giganteum*; the other flowers had a pinkish tint, and the plant sold under the name of C. Macowani. Mr. WORSLEY regarded this as a form of *C. latifolium* from the most southern part of the range of that species.

Hybrid Japanese Plum and Peach.—Mr. LAXTON showed an interesting hybrid raised between the Japanese Plum ♀ and the Peach Sea Eagle ♂. The foliage of this hybrid is illustrated at fig. 181 in Rept. International Conference (1906) on "Genetics." This year the hybrid has flowered for the first time, the flowers being white with the faintest tinge of pink in the bud stage, the filaments of the stamens white and stouter than those of the Japanese Plum, the anthers well developed, and pollen apparently properly formed, the flower as large as that of the Peach. No pistil was present in any of the flowers shown, but a photograph showed the style and stigma developed in some of the flowers. No fruits have, however, been so far perfected, the ovary being frequently absent even when the style and stigma are present. (See *Gardeners' Chronicle*, April 20, p. 256, figs. 109, 110.)

Pruning and protection of Gooseberry bushes.—Mr. J. F. BAKER showed a branch, completely furnished with blossom throughout its entire length of over 3 feet, from a Gooseberry bush. It had been regularly summer pinched every June, but not otherwise pruned. Several snags left at the last pinching were still present, and at the base of each one or two blossoms showed that the pinching of the young shoot had induced fruit formation. Each autumn the bush had to be bound up with string, so that the branches were brought near together and kept as upright as possible to prevent disbudding by birds, which abound in the district. The string was removed each spring. He stated that as a result of his experiments, extending over several years, he had for the last two or three years adopted these methods extensively, very little trouble or expense being involved, and the results were excellent. A branch from a bush treated and left in the ordinary way, growing in the same plot, was also shown, and this was almost denuded of buds.

MIDLAND DAFFODIL.

APRIL 23 & 24.—The ninth annual exhibition of the Midland Daffodil Society was opened on Tuesday last in the Botanical Gardens, Edgbaston, Birmingham. It was larger than any of its predecessors, and the increase was almost entirely due to the greater number of competitive exhibits. The available space in the gardens for such exhibitions as this being somewhat restricted, a departure was made this season in respect to the Midland Auricula and Primula Society's show, which for several years past has been held on the same day as the Daffodil show. It was decided to postpone the Auricula show until May 1, but even when this had been done, it was exceedingly difficult to accommodate all the Daffodils and Tulips, &c., which filled the Exhibition Hall, the conservatory, and even part of the corridor leading from the entrance gates to the Water Lily house.

There are so many classes for seedlings and new varieties in the Midland schedule, that there are always numerous novelties exhibited at Birmingham. The non-competitive exhibits from Mr. ENGLEHEART, Mr. WILSON, and others were composed entirely of novelties, whilst in the competitive groups from Mr. CROSFIELD and Mr. WILLIAMS there were many new varieties of great merit.

Six Awards of Merit were awarded to new Daffodils, all of which are described below.

The display of honorary and competitive exhibits, consisting mainly of Narcissus, but including some Tulips, Cinerarias, Hippeastrums, rockwork, Alpine plants, &c., was very bright.

There were many visitors, and some exhibitors from the extreme south-west of England, Ireland, Wales, London, and the southern counties. Among the visitors were Sir Pieter Bam, Mr. C. du Chiappini (South African Exhibition), Miss Willmott, &c.

It was generally remarked that the Botanical Gardens were in excellent condition, and many congratulations were offered to Mr. Humphreys, the genial curator.

The "Barr" Cup was again won by the redoubtable amateur, Mr. R. C. CARTWRIGHT.

The Champion Medals offered by the Birmingham Botanical and Horticultural Society were not awarded at the time our report was written.

In the evening of the first day the exhibitors, judges, and visitors were entertained at dinner by Mr. Robert Sydenham at the Grand Hotel. The Rev. G. H. Engleheart read a short paper on "Notes and Notions About Daffodils."

MIXED DAFFODILS.

The first class was one for 50 varieties fairly representing the three types magni-coronati, medio-coronati, and parvi-coronati, and including Polyanthus Narcissus. The 1st prize was awarded to Mr. F. H. CHAPMAN, Rye; the winner last year was Mr. Crofield. Extraordinarily good culture was seen in the winning collection, every flower being finely developed, as was exemplified in the magnificent perianths of Barcarolle and many other varieties. Messrs. POPE & SON were 2nd, and Mr. R. C. CARTWRIGHT 3rd.

AJAX OR TRUMPET DAFFODILS.

The 1st prize in a class for nine distinct varieties of yellow, self-trumpet Daffodils was awarded to Messrs. POPE & SON, King's Norton. This firm staged the following varieties:—Olympic, Glory of Leiden, King's Norton, Quintus, Progress, Andronicus, Surprise, "A Mere Seeding," and Captain Nelson. Mr. R. C. CARTWRIGHT, King's Norton, who won the 2nd prize, had some excellent flowers of Glory of Leiden, Emperor, M. J. Berkeley, P. R. Barr, &c. 3rd, Mrs. F. M. WALTON, Handsworth.

A very pretty collection of bicolor trumpet Daffodils was shown by Messrs. POPE & SON in the class for nine varieties. The three "back-row" flowers were Horsfieldi, Madame de Graaff, and Grandee. In the centre row, Rembrandt, Mrs. Galton, and Glory of Noordwick found a place, and in the front were J. B. M. Camm, Mrs. Betteridge, and Mrs. Camm. A very pretty group from Mr. R. C. CARTWRIGHT obtained the 2nd prize, and Mrs. F. M. WALTON won the 3rd prize.

INCOMPARABILIS OR CUP DAFFODILS.

The next class was one for varieties of the medio-coronati type possessing yellow or sulphur-coloured perianths, and in this competition Mr. R. C. CARTWRIGHT beat Mrs. F. M. WALTON and Messrs. POPE & SON with the following varieties:—Sir Watkin, Princess May, Frank Miles, Conspicuous, Leonie, Glitter, Gloria Mundi, Beauty, and Gwyther; Mrs. F. M. WALTON was 2nd, and Messrs. POPE & SON 3rd.

A similar class for flowers having white perianths was represented by three exhibits, and the winners of the 1st prize—Messrs. POPE & SON—staged the following varieties: White Lady, Will Scarlett (excellent flowers), Marina, Lady M. Boscawen, Rebecca, White Queen, Dorothy Yorke, Mabel Cowan, and Lucifer; Mr. R. C. CARTWRIGHT was 2nd, and Mrs. F. M. WALTON 3rd.

THE POET'S NARCISSUS.

The parvi-coronati section was shown in twelve varieties, and a very pretty collection from Mr. R. C. CARTWRIGHT obtained the 1st prize; his collection consisted of Saturn, Firebrand, Blood Orange, Robert Browning, Falstaff, Bullfinch, Dorothy, Ellen Barr, Jno. Bain, Agnes Barr, Baroness Heath and Vanessa. The highest colour was seen in the variety Firebrand. Messrs. POPE & SON won the 2nd prize.

The best collection of six varieties of the true poeticus type was shown by Mr. F. H. CHAPMAN, Bath, who had Barcarolle, Virgil, Horace, Cassandra, Homer, and White Elephant. All these varieties possess high merit, but some of them are nearly alike, as seen at an exhibition, although they may exhibit greater degree of distinctiveness in the garden. The Rev. J. JACOB, Whitchurch, was placed 2nd, and Mr. R. C. CARTWRIGHT 3rd, there being two other exhibitors in the same class.

INEXPENSIVE DAFFODILS.

When novelties can only be purchased at 50 many pounds per bulb, it is useful to know of other sterling varieties that are sold cheaply. The following classes were intended to indicate the best of these inexpensive Daffodils:—

Collection of Daffodils in twenty-five varieties, none of which shall cost more than ten shillings per bulb. There were six or more collections in

this class, and amid the keen competition Mr. H. B. YOUNG, Lincoln, won the 1st prize. The exhibit contained five excellent flowers of Glory of Leiden, which made a bold central feature, and Madame de Graaff, Emperor, and other trumpet flowers were around them, whilst the medio-coronati and parvi-coronati types were equally well represented. The varieties were as follow:—Empress, Barrii conspicuus, Emperor, Katherine Spurrl, Maximus, Stella Superba, Crown Prince, Lucifer, Minnie Hume, Glory of Leiden, Poeticus grandiflorus, Præcox, Frank Miles, Queen Sophia, Madame Plemp Branst, Gloria Mundi, Madame de Graaff, C. J. Backhouse, Mrs. Ware, Ornatus, J. B. M. Camm, Lulworth, Mrs. Langtry, John Nelson, and Jno. Bain. Mr. W. A. WATTS, St. Asaph, was 2nd, and Mr. A. R. GOODWIN, Kidderminster, 3rd.

Six distinct varieties, costing not more than three shillings per dozen! Messrs. POPE & SON offered five prizes in this class. Mr. C. L. BRANSON, Coleshill, won the 1st prize with the varieties Victoria, Emperor, Flora Wilson, Horsfieldi, Stella superba, and Barrii conspicuus. There were many competitors.

SEEDLINGS AND NEW VARIETIES.

Group of twelve varieties of seedling Daffodils that have not been in commerce four years. Not fewer than two nor more than five stems of each variety could be shown. The first prize was awarded to Mr. E. M. CROSFIELD, Wrexham, for one of the best exhibits in the competitive classes. His flowers were as follow:—Banzai, a very large trumpet Daffodil with sulphur-coloured perianth and lemon-coloured, much frilled trumpet; White Slave, Fiona (self-coloured trumpet flower, sulphur, or very pale lemon); Compass (sulphured perianth and broad, much-flattened, deep orange-coloured crown); Countess of Stamford, a trumpet flower, almost white throughout, but with sulphur tint; Giraffe, with a light-yellow perianth, and rather short, much-spreading, buttercup-coloured trumpet; Fantasy, a nearly white trumpet flower with long, slender trumpet; Tartar (of poeticus type with excellent, flattened, deep orange-coloured crowns); Mrs. Ernest Crosfield, nearly white trumpet flower; Harmony, a large trumpet flower, in which the trumpet is of richest golden yellow, and the perianth pale sulphur; Circlet, sulphur-tinted perianth and lemon crown, with orange margin; and Lola, a pale sulphur-coloured trumpet flower; 2nd, Miss SPURKELL, Norwich; and 3rd, Messrs. POPE & SON. There were several other exhibits in the class.

Three distinct varieties (any section) not in commerce. Mr. P. D. WILLIAMS, St. Keverne, won the 1st prize, showing the varieties Comet, whitish perianth and fine, blood-orange chalice; Edgar, similar perianth, with yellow crown, having green eye; and Godoy, a variety with orange-coloured crown, having greenish centre. Of the five other exhibitors in the class the most successful were Messrs. POPE & SON.

Three distinct varieties of magni-coronati section, raised by exhibitor, and not in commerce. Mr. E. M. CROSFIELD, who was awarded the 1st prize, showed the following varieties:—Majestic, very large, having sulphur-coloured perianth and deeper-tinted trumpet, which is much frilled, very fine; Indamora, of nearly the same shades as Majestic; and Uncle Robert, an exceedingly large trumpet flower, in which the most prominent feature is the very large, widely-expanded trumpet. 2nd, Mr. J. MALLENDER, Worksop.

Three distinct varieties of medio-coronati. Mr. P. D. WILLIAMS, St. Keverne, won the 1st prize in this class, and showed "Seville" (Award of Merit), Water Lily, a very beautiful, pure white variety; and Hestia, a flower with very large, spreading perianth of a sulphur shade, and yellow chalice with greenish eye, and brilliant orange-coloured margin. 2nd, Mr. E. M. CROSFIELD, in whose exhibit the variety Comet was remarkable for its very deep orange-coloured crown.

Three distinct varieties of parvi-coronati seedlings. 1st, Mr. P. D. WILLIAMS, showing Aphrodite (Award of Merit); Hornet, a flower of excellent form, and having sulphured-shaded perianth, with the deepest orange-coloured crown, which is much flattened; and Poseidon, perianth nearly white, and the crown of greenish yellow, with orange-coloured ring. 2nd, Mr. E. M. CROSFIELD.

Awards of Merit.

Aphrodite.—A very large flower of the parvi-coronati type, possessing excellent form. Perianth pure white, with green base to the crown, and the frilled margin yellow. A very pretty flower. Shown by Mr. P. D. WILLIAMS.

Seville.—This variety belongs to the medio-coronati type. The flower possesses excellent form if the perianth is pressed flat, but at present it appears rather wavy and irregular. The magnificent "cup" is of the richest, orange-colour, and very spreading. The variety may prove to be a rare acquisition, and it certainly will, if greater substance and smoothness can be developed in the perianth. Shown by Mr. P. D. WILLIAMS.

Brilliantcy.—An extremely large flower of the medio-coronati group. Perianth of a rich yellow colour, exceedingly large; cup short and widely expanded, colour of cup yellow, with brilliant orange band. Shown by R. H. BATE, LTD.

Corallina.—An incomparabilis flower, with the palest sulphur-coloured perianth, and straight cup with notched margin free from frill, and self-coloured pale orange approximating to coral. The Award was probably given for the novel shade of colouring. Shown by Messrs. BARR & SONS.

Glitter.—A medio-coronati flower, perianth of a rich lemon shade, and the cup of reddish orange, becoming paler to yellow at base. A well-formed flower of moderate size. Shown by Mr. ROBT SYDENHAM.

Kestrel.—A very fine variety of the poeticus type. Perianth white, with well-developed, flattened crown of rich blood-orange colour. Shown by Mr. A. M. WILSON.

Caltha polypetala.—A strong-growing Caltha that was awarded an Award of Merit by the Royal Horticultural Society, April 17, 1906.

PREMIER BLOOMS.

Prizes were offered for the best single bloom of each of the following types. We append the names of the winning varieties:—Magni-coronati, yellow self trumpet, King Alfred; Magni-coronati, bicolor, cream, white, or any other type of trumpet Daffodil, Frost Bound; Medio-coronati, yellow or sulphur perianth only, Home Truth; Medio-coronati, white perianths only, Empire; Parvi-coronati, poeticus varieties excluded, Astræa; True poeticus type, Horace.

DAFFODILS AND TULIPS IN POTS.

Excellent cultivation was observed in some of the examples of Narcissus growing in pots, the variety Madame de Graaff forming the subject of frequent comment. Mr. W. H. PARTON and J. A. KENRICK, Esq., Harborne (gr. Mr. Usher), won the 1st prizes for Daffodils; and J. A. KENRICK, Esq., Mr. W. H. PARTON, Mr. R. C. CARTWRIGHT, and Mr. P. WILLIAMS won the 1st prizes for Tulips and Polyanthus, &c.

AMATEURS' CLASSES.

We may briefly allude to some of the classes exclusively reserved for amateurs. Mr. H. B. YOUNG won the 1st prize for six distinct varieties of the Medio-coronati type, with white perianths; and Mr. A. R. GOODWIN for varieties with yellow or sulphur-coloured perianths. The 1st prize for six varieties of Parvi-coronati (including Engleheartii type, but excluding true poeticus) was also won by Mr. YOUNG, who was followed by Mr. A. R. GOODWIN.

Mr. GOODWIN had an excellent exhibit of six varieties of the true poeticus type, showing Horace, Dante, Virgil, Herrick, Homer, and Laureate.

Mrs. GUMBLETON, Tewkesbury, won the 1st prize for three distinct varieties of double Daffodils; and J. A. KENRICK, Esq., the 1st prize for three varieties of Polyanthus Narcissus.

There were classes for exhibitors who had never won a 1st or 2nd prize in the Birmingham exhibition, and Mr. W. MARPLE, Penkridge; Mr. E. DEAKIN, Hay Mills; Mr. MILES JOHNSTON; and Mr. WALLACE DAVIES won 1st prizes.

DECORATIVE CLASSES.

The principal decorative class was one for a group of cut, hardy, spring flowers, arranged on a round table 2½ feet in diameter, suitable for the drawing-room. There were six tables so arranged, and the 1st prize was given to an exhibit of Muscari and Lily of the Valley flowers arranged in silvered rustic stands over a blue cloth. The

award was criticised from the point of view that the effect of the cloth detracted from the flowers. This may have been so, but the cloth so perfectly toned with the flowers that the whole, judged as a "blue" floral ornament, was agreeable to the eye, if not in accordance with the general practice of using a neutral ground, or one calculated to "throw up" the colour of the flowers. This exhibit was shown by Mr. S. S. JONES, Prees; Messrs. POPE & SON obtained the 2nd prize for a neat arrangement of Narcissus incomparabilis varieties which, in the opinion of some, should have been placed 1st. There were several other classes for vases, bowls, and epergnes of Narcissus flowers, and in most of them there was much competition for the awards.

HONORARY EXHIBITS.

These were numerous, and whilst most of them were composed of, or contained Narcissus, others were of different character.

The only Gold Medal was one awarded to the Rev. GEO. ENGLEHEART, Dinton, near Salisbury, for a collection of seedlings under numbers, and therefore of little value for descriptive purposes. Mr. ENGLEHEART's exhibits nowadays are not confined to the poeticus type, but incomparabilis and trumpet Daffodils are seen amongst his novelties, as well as varieties obtained partly from the pretty little *N. triandrus*.

Messrs. BARR & SONS, King Street, Covent Garden, London, W.C., made a most extensive exhibit of Narcissus flowers, which was rich in novelties of the highest merit. Some of the firm's newest seedlings were exhibited under numbers, reference to them individually would, therefore, be of little value. With these were some superb flowers of Weardale Perfection, Lord Roberts, George Philip Haydon, Peter Barr, Cygnet, Chancellor, Royal Star, Scarlet Herald, with sulphur-yellow perianth and brilliant orange-coloured, flattened crown, White Virgin, &c. (Silver-Gilt Medal.)

Miss F. W. CURREY, The Warren Gardens, Lismore, Ireland, had a capital exhibit of Daffodils, the flowers being remarkable for excellent form and brilliant colouring. Lady of the Snows, Madame de Graaff, King Alfred, Child of the Mist, Cygnet, and Avalanche were unsurpassed amongst the trumpet varieties, and Joan of Arc, Beacon, and Lucifer were prominent amongst the incomparabilis. (Silver-Gilt Medal.)

From the LISSADELL BULB FARM (Sir J. Gore-Booth), Ireland, was sent a collection of Narcissus blooms exhibiting superb cultivation, especially in the case of Madame de Graaff, which was unusually good, the flowers possessing rare size and substance. The large trumpet variety Glory of Leiden, amongst a large number of varieties, was excellent. (Large Silver Medal.)

Mr. A. M. WILSON, East Keal, exhibited some seedlings, one of which is described under "Awards of Merit." Orangeman, with fine, orange-coloured trumpet and pale sulphur perianth; Greeneye, with sulphur-coloured perianth and yellow cup possessing a green "eye"; Homespun, Stonechat, &c., were of much merit. (Large Silver Medal.)

Mr. R. H. BATE, LTD., The Floral Farms, Wisbech, made an extensive exhibit of Narcissus, in which the various types of the flower were well represented. Amongst the large trumpet flowers were such varieties as Weardale Perfection, Glory of Leiden, King's Norton, Snow Queen, Madame de Graaff, Madame Plemp, and King Alfred. Of the parvi-coronati section, some of the more prominent were Præcox grandiflorus, Baroness Heath, Nelsoni aurantius, C. J. Backhouse, Beauty, Lucifer, Barrii conspicuus, Gloria Mundi, &c. (Large Silver Medal.)

Messrs. W. H. SIMPSON & SONS, Birmingham, had a group of Daffodils, in which Madame de Graaff formed a good central feature, and the rest of the flowers were relieved with some pots of Narcissus placed at intervals amongst them. (Large Silver Medal.)

Messrs. HOGG & ROBERTSON, 22, Mary Street, Dublin, showed a very admirable display of Narcissi, which was particularly noticeable for careful selection in the flowers and neat, effective staging. Excellent cultivation was evident in this exhibit, the numerous varieties being quite up to the best standard. A group of Tulip flowers was just as remarkable for a very flower of the brilliant, scarlet species *T. F.*

the segments of which were 5 inches in length; the new *T. Fosteriana*, scarlet, with yellow base; and a number of good varieties were included in the exhibit. (Large Silver Medal.)

Messrs. DICKSON'S, LTD., Chester, had a group of *Narcissus* flowers, including many varieties, amongst which the well-known white incomparabilis *Elaine* was pretty. *N. poeticus præcox* was shown well. (Small Silver Medal.)

Messrs. GILBERT & SON, Anemone Nurseries, Dyke, Bourne, Lincolnshire, showed flowers of their brilliantly-coloured *Anemones*, and, in addition a collection of *Daffodil* flowers, *Fritillarias*, &c. (Silver Medal.)

The Rev. G. P. HAYDON, Westbere, Canterbury, showed some seedling *Daffodils* with extraordinary names, amongst which were Bull Pup, Giraffe, The Secretary, Lacquer Ware, &c.

Mr. ROBERT SYDENHAM, Tenby Street, Birmingham, exhibited a collection of *Narcissus*, *Tulips*, *Irises*, *Fritillarias*, *Lily of the Valley*, &c., growing in moss-fibre in glazed green vases, without means of drainage. (Silver Medal.)

Mr. S. MORTIMER, Rowlledge Nurseries, Farnham, Surrey, had a dozen or more large trumpet-shaped glasses furnished with excellent winter-flowering or tree *Carnations*, the varieties being similar to those usually seen at the London shows. In addition, Mr. MORTIMER exhibited flowers of a good double white *Stock*, named "All the Year Round." (Silver-Gilt Medal.)

Messrs. "BAKERS," Wolverhampton and Codrall, had natural rockwork arranged as a bank on a table and sloping to the wall. The effect was very pleasing. The projections, and more exposed positions were planted with species of *Saxifraga*, *Aubrietia*, *Hutchinsia alpina*, *Sempervivum*, &c., and the sheltered depressions with varieties of *Primula Sieboldi*, *P. nivalis*, *Cypripedium nivale*, *Iris pumila*, *Lithospermum prostratum*, &c., whilst *Acers* and some other dwarf-growing shrubs and *Dicentra* (*Die-litra*) *spectabilis* were at the top of the Rockery. (Silver-Gilt Medal.)

Messrs. GUNN & SONS, Olton, Birmingham, exhibited rockwork planted with species of flowering plants. The employment of numerous *Violas* had the result of making the exhibit very gay. (Large Silver Medal.)

Messrs. DOBBIE & Co., Rothesay, had a gay exhibit of *Anemone* flowers in great variety, and a collection of varieties of *Viola*. (Silver Medal.)

Messrs. KER & SONS, Aigburth Nursery, Liverpool, staged a grand group of *Hippeastrums*, many of the varieties being of exceptional merit, but particularly that known as *Rose Madder* of the new tint that was so greatly admired in Messrs. KER's exhibit at the Temple Show last season. (Large Silver Medal.)

Messrs. SUTTON & SONS, Reading, showed a large group of *Cinerarias* in pots; the varieties being of shades of pink and blue. The same firm had some plants of a single *Ranunculus* with brilliant crimson flowers. (Large Silver Medal.)

Messrs. WALLACE & Co., Kilnfield Nurseries, Colchester, showed an exhibit containing selected varieties of *Narcissus* and *Tulips*. In addition were a few hardy flowers of a miscellaneous character. (Silver Medal.)

The Misses HOPKINS, Barming, Maidstone, showed some coloured *Primroses* and other species of *Primula*.

Messrs. FELTON & SONS, Florists, Hanover Square, London, exhibited good arrangements of cut flowers. (Silver-Gilt Medal.)

HUNTS DAFFODIL SPRING FLOWER.

APRIL 18.—The second show of the above-named society was held on this date. Principal prize-winners were Lady LILFORD (winner of the Silver Vase offered by Messrs. Barr and Sons), H. R. DARLINGTON, Esq., Mrs. NOWELL USTICKE, Hon. Mrs. DUBERLY, Sir CHARLES HAMILTON (president), and the popular secretary, Miss L. L. LINTON. The attendance was much larger than that of last year. Honorary exhibits were staged by Messrs. BARR & SONS, King Street, Covent Garden; Messrs. R. H. BATH, LTD., Wisbech; Messrs. W. and J. BROWN, Peterboro'; Messrs. J. E. PERKINS, Huntingdon; Messrs. LAXTON, of Bedford; Mr. ROBERT SYDENHAM, Birmingham. Lady DE RAMSEY's exhibit of *Carnations* also came in for much admiration. The Right Hon. the Earl of SANDWICH sent an exhibit of star *Cinerarias*, *Azaleas*, *Dracænas*, *Caladiums*, &c., which were tastefully displayed.

ROYAL BOTANIC.

APRIL 24.—The exhibition of the above Society held on this date was favoured with splendid weather, and a very pretty show was attended by many visitors. The great conservatory was brilliant with groups of *Roses*, forced shrubs, *Cinerarias*, and *Zonal Pelargoniums*, in addition to the usual occupants, and the corridor was entirely filled with exhibits of seasonable flowers.

The *Roses* and flowering shrubs were staged by Messrs. W. PAUL & SON, Waltham Cross, Herts, and they made quite a bank of flowers. The *Roses* were principally pillar varieties, the White Waltham Bride being shown in excellent condition, with *Wedding Bells*, whose pale rose semi-double flowers hung in clusters; the bronze *Crepuscule*; *Nymph*, a charming single variety, with creamy white petals; *Kathleen*, another single, and a new one named *Tausendschön*, to which a certificate was awarded. The flowers are large, and are disposed in big clusters; their colour is pale rose, but in the opening buds the shade is richer and deeper. The shrubs included *Cherries*, *Peaches*, *Apples*, *Cydonia japonica*, *Choysia ternata*, &c. (Gold Medal.)

Messrs. H. CANNELL & SONS, Swanley, Kent, had large bunches of brilliant *Zonal Pelargoniums*, with star *Cinerarias* at the back, and interspersed with plants of *Grevillea robusta*. The following is a list of some of the choicer varieties of *Pelargoniums* with their colours: *Queenswood*, delicate salmon; *Kingswood*, flame scarlet, the top petal is white at its base; *Lilacina Improved*, purple-pink, the pips are exceptionally large; and *Frogmore*, the largest of the magenta-coloured varieties, with a scarlet marking in the posterior petal. (Silver-Gilt Medal.)

EDWARD WAGG, Esq., The Islet, Maidenhead (gr. Mr. D. Phillips), was awarded a Gold Medal for a fine display of *Cinerarias*, including both the florists' and the lax-flowered type.

Lady TRESS BARRY, St. Leonard's Hill, Windsor, Berks, exhibited a very large number of *Camellias* from the open. The collection was very representative, and several seedlings were included, notably a single of dark-red colour named *Sir F. T. Barry*, and to this a Certificate of Merit was awarded. (Gold Medal.)

Messrs. H. B. MAY & SONS, Dyson's Lane Nurseries, Upper Edmonton, staged a group of hardy and another of exotic *Ferns*, some very large *Pansies*, dwarf *Roses*, *Statice profusa*, and a hybrid *Pelargonium* named *Millfield Gem*. (Silver-Gilt Medal.)

Mr. JAMES DOUGLAS, Edenside, Great Bookham, showed a fine batch of *Auriculas*—principally *Alpine* varieties. New varieties of merit were *May Day*, a yellow fancy after *Daffodil*, only paler: the form and size are both good: it is a little lacking perhaps in the best type of paste; *Mikado*, a very dark crimson-maroon self, with a dense paste set in an even ring; and *Argus*, having petals edged with vinous red, merging into a darker Plum colour and with a white centre. Each of the foregoing plants received the Society's Certificate of Merit. (Silver-Gilt Medal.)

H. R. DARLINGTON, Esq., Park House, Potter's Bar (gr. Mr. D. Bignell), showed 71 varieties of *Daffodils*, including examples of most of the sections, all in the best condition, and to which was awarded the Cup offered by Messrs. Barr for the best display of these flowers in the show.

Messrs. HOGG & ROBERTSON, 22, Mary Street, Dublin, showed a fine display of *Daffodils*, amongst which we noticed *Countess Cadogan*, with a white trumpet; *Mona*, a fine *Poet's Daffodil*; *Lady Arnott*; and *Mrs. C. R. Hamilton*, of the incomparabilis section, and with a rich open cup. *Tulips* and a few hardy flowers were also displayed by the same firm. (Gold Medal.)

Messrs. BARR & SONS, King Street, Covent Garden, W.C., had vases of choice *Daffodils*, all in the best condition, a selection of *Tulips*, and seasonable hardy flowers. *Narcissus Cygnet* was selected for Award; it has a refined canary-yellow-coloured trumpet set in a perianth of creamy-white. (Gold Medal.)

Messrs. THOS. S. WARE, LTD., Feltham, Middlesex, showed *Alpine* and hardy flowers, tree *Pæonies*, and *Carnations*. (Silver-Gilt Medal.)

Messrs. JOHN PEED & SON, West Norwood,

London, had a display of *Alpine* plants, bulbous flowers, *Clematis*, *Pansies*, and a batch of hardy succulent plants. (Silver Medal.)

The SOCIETY exhibited *Streptocarpus grandis* in flower. Only one very large ovate leaf is developed, and this is addressed. One plant bore six flowering spikes, which were curiously developed one behind the other in the same plane. The lax cymose inflorescence has small pale lavender flowers.

LINNEAN SOCIETY.

APRIL 18.—Dr. A. Smith Woodward, F.R.S., vice-president, in the chair. Mr. James Saunders, A.L.S., showed a series of lantern-slides of "Witches' Brooms," which are usually caused by one of three agents, parasitic fungi (*Æcidium* and *Exoascus*), parasitic insects and gnarling. The illustrations shown were of trees affected by parasitic fungi, the mycelium of which permeates the woody tissue of the diseased plants. They included *Silver Fir*, *Norway Spruce*, *Common Elm*, *Hazel*, *Hornbeam*, *Birch*, *Elder*, *Hawthorn*, and *Wild Cherry* (*Prunus avium*). The *Silver Fir* was from Norfolk, but all the others from South Bedfordshire and North Hertfordshire.

The first paper was by Mr. J. C. Shenstone, F.L.S., "On the Ecological Functions of Stolons and Cleistogamous Flowers." He pointed out the advantages to the plants by the colony-forming habit such as its more certain pollination, and greater power of holding its own against competitors, instancing as examples *Bellis perennis*, *Thymus Serpyllum*, and *Mercurialis perennis*. Further examples were dwelt upon in the cases of *Urtica dioica*, *Adoxa Moschatellina*, and the *Violets Viola odorata* and *V. canina*, where both stolons and cleistogamous flowers co-operate in keeping the colonies compact.

Mr. A. O. Walker, F.L.S., then introduced the subject, "The Conservation of existing Species by Constitutional or Physiological Variation giving greater power of adaptation without perceptible change of structure." The author referred to a supposed case of two healthy men going to an unhealthy climate: one proving immune to the local diseases might conceivably transmit that quality to his children; the other, falling a victim to the climate, would leave no descendants. In the case of plants he brought forward the case of *Crepis taraxacifolia*, long known in Wales as a rarity, which in 1896 onwards became extremely abundant at Colwyn Bay. He considered that this might be accounted for by the introduction of a different variety, morphologically identical, yet physiologically distinct, which, by its ability to adapt itself to its surroundings, had rapidly extended its area of growth. Another case was of *Cardamine pratensis*, usually stated to grow in moist meadows, which is accurate as regards North Wales, but in Kent, its favourite habitat is coppice woods, the second year after cutting the undergrowth. It is frequent on dry banks, on masses of rocks, of trees or shrubs, probably as xerophilous a station as could be imagined. *Parnassia palustris* may also be found in exceptionally dry places.

Mr. Hugh Scott gave the substance of his paper, which was communicated by Mr. J. J. Lister, F.R.S., F.L.S., "On an Aberrant Coccid."

The last paper was by Prof. W. B. Bottomley "On some Results of Inoculation of Leguminous Plants." After briefly adverting to the known facts of nitrogenic bacteria in root-nodules, the author stated the results of some experiments made last year at the College Farm, Kilmarnock, on *Lucerne* (*Medicago sativa*), which induced him to repeat the experiments in his own laboratory. In May, 1906, experiments were begun; *Tares* (*Vicia sativa*) were chosen and inoculated seeds set in sterilised sand, to which the requisite potash and phosphate salts had been added. A second set of pots was prepared with untreated seed, but besides the potash and phosphate, nitrate of soda proportionate to 2 cwt. per acre was added. In the last week of July the results were tested and found to be:—*Tares*, with nitrate of soda, yielded 1.92 per cent. nitrogen; *Tares*, inoculated, yielded 3.07 per cent. nitrogen; showing that the latter contained over 50 per cent. more nitrogen than those grown with nitrate of

soda, the food value being correspondingly increased. Specimens of field crops were obtained from Scotland to check these results, in September, and the three experimental plots proved:—Section A: No nitrogenous manure, 3.41 per cent. nitrogen; Section B: Nitrate of soda, 3.75 per cent. nitrogen; Section C: Inoculated, 4.04 per cent. nitrogen. Here the differences are less, due to the fact that farm soil invariably contained a certain number of the nitrogenous bacteria, which accounted for these results. Section B showed a yield of 9 tons 8 cwt. per acre, and Section C (inoculated) showed 12 tons 5 cwt. of fodder.

ORCHID SALES—WESTFIELD DUPLICATES.

The sale of duplicate Orchids from the Westfield collection of FRANCIS WELLESLEY, Esq., at Messrs. Protheroe and Morris' Rooms, Cheap-side, on Tuesday and Wednesday, April 23 and 24, notwithstanding the number of similar events this season, proved satisfactory, the 570 lots realising £1,800. The plants were mostly good specimens, and all were in excellent condition. The white Cattleyas sold well, a small healthy plant of *C. labiata* "The Empress" realising 55 guineas; *C. Mossiae* Arnoldiana 20 and 16 guineas; *C. labiata alba* "Louise" 36 guineas, *C. Mossiae* "Gloire de la France" 21 and 17 guineas, *C. Mossiae alba* "Miss E. Harting" 40 guineas, *C. Mendelli* "Mrs. Frederick Knollys" 21 guineas, and other recognised good forms, both albinos and coloured, fetched good prices throughout. As at the sale last year, *Cypripedium Thalia* "Mrs. Francis Wellesley" (a small healthy plant) reached the highest price, 120 guineas; *C. Mrs. Wm. Mostyn*, Westfield variety, fetched 27 guineas; *C. "King Edward VII."* 16 and 14 guineas, and all others went well. *Lælio-Cattleyas* and *Cattleyas* of the older kinds sold well, and although it might be said to be a buyers' sale, by reason of being without reserve, it still showed the healthy tone of the market.

DEBATING SOCIETIES.

CROYDON & DISTRICT HORTICULTURAL.

"General Management of Pleasure Grounds" was the title of a paper read before the members of this society on Tuesday, the 16th inst., by Mr. J. C. Lewis, Reydon Mount Gardens, Croydon. The lecturer gave details of work in the pleasure grounds in each month. Beginning with October, which may be described as the commencement of the gardener's year, he detailed operations as each season comes round, so that at the end of September the cycle of work in the outside garden was completed.

READING AND DISTRICT GARDENERS'.

There was a very large attendance of members at the last meeting of this association, which was held in the Abbey Hall, and presided over by Mr. W. Turnham. The committee had arranged some interesting competitions, and these proved a great success. The first contest was the making of a gentleman's buttonhole and a lady's spray. Head gardeners and foremen were debarred from competing, but the second competition was open to all, and was for five small vases arranged for effect and suitable for a breakfast table. Mr. W. H. Watson was successful in both classes. A magnificent display of cut flowers was made by the members, and next morning the flowers were conveyed to the Royal Berkshire Hospital. In addition a collection was taken at the meeting in aid of the funds of this hospital, and a sum of about 60s. was realised.

THE WEATHER.

THE WEATHER IN WEST HERTS.

Week ending April 24.

A long continued rainfall. The first four days of the week were cold, but since then the weather has been getting warmer. To-day the maximum reading in the thermometer screen was 70°, which is the highest as yet recorded here this year. On the other hand, on the three cold nights the exposed thermometer registered from 9° to 11° of frost. The ground is now becoming warm again, being at about an average temperature at 3 feet deep, and 8° warmer than is seasonable at 1 foot deep. Rain fell on two days to the total depth of over half an inch. This was really one continuous fall, for the rain began at 8 p.m. on the 20th and continued with only four hours intermission until 8 p.m. on the 21st, or for 24 consecutive hours. This fall re-started both the percolation gauges, but the amounts now passing through them are very small. The sun shone on an average for 5½ hours a day, or for a quarter of an hour a day longer than is usual at this season. Calms prevailed in the early part of the week, but since then the wind has been moderately high. The mean amount of moisture in the air at 3 p.m. was 1 per cent. in excess of a seasonable quantity for that hour. In my last report the date of the first swallow was given as April 13, whereas it should have been April 12. E. M., Berkhamsted, April 24, 1907.

MARKETS.

COVENT GARDEN, April 24.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—Ed.]

CARBONIC ACID GAS: A PUZZLE.

IT is universally recognised that one of the chief elements in plant-growth is carbonic acid gas, which is absorbed through the pores of the foliage, and there transmuted by solar action on the chlorophyll into compounds, which form the solid parts of the structure, and also play a material part in developing the innumerable secretions of plant life. This is effected by dissociating the carbon from the oxygen, and forming fresh combinations. One result of this, however, is that a proportion of this absorbed carbon in all trees and woody plants, and, probably, to a less extent, in succulent ones, eventually finds its way to the soil as a practically imperishable residuum, such as is seen in immense deposits of coal of various kinds, including peat, and, in short, of all vegetable contributions to the earth's strata. Annually, therefore, an immense amount of carbon, of which much is locked up in the earth, is extracted from the atmosphere. This process, too, has doubtless continued uninterruptedly from the in-

conceivably remote period when vegetation first commenced, and this brings us to the puzzle we have in mind. We are taught that the balance is maintained by the fact that, while all the members of the vegetable kingdom absorb carbonic acid gas, those of the animal kingdom exhale it by dissociating the gases contained in the air they breathe and the food they consume, using the oxygen to revitalise the blood and throwing off into the air the carbonic acid gas produced in the processes. In this way there is undoubtedly a large return, but it can be only a partial one. In the first place, this leaves out of account entirely the constant removal of that which, as we have seen, becomes locked up permanently in the soil; and, in the second place, when the relative proportions of plant-life and animal-life in the earth's surface are considered, there is apparently, and, I believe, really, an enormous relative difference in favour of the plant-world. Vast areas of the terrestrial surface are densely clothed with vigorous forest vegetation, and by far the greater part with vegetation of some kind, the comparative areas of absolute desert being small. The latter, too, scarcely affects the question, since animal life, being almost dependent, directly or indirectly, on vegetable life, is equally absent where vegetation fails. Now, if we examine these forestal and other areas where vegetation is rife, even if we take into account the insect world with its myriads, and make every allowance for the capacity of animals to hide themselves, their numerical proportion falls infinitely short as compared with that of all the plants, every leaf of which during the growing season is actively engaged in absorbing carbonic acid gas from the air as a preliminary to solidifying a proportion and putting it out of circulation. Leaving the dry land, and turning to the ocean as a possible source, we find no solution there, for over the vegetable kingdom therein ranging, from the immense seaweeds of the Sargasso Sea to the microscopic vegetation which pervades the waters, the animal life cannot possibly preponderate, for the simple fact that rules here as on land, viz., that the animal can only exist by consuming the vegetable directly or indirectly, since carnivora live by devouring the vegetarians, and preponderance of animal life anywhere is, therefore, an impossibility, nor—and this is very important—can an animal give out more carbonic acid than it takes in in the shape of food. Hence we are confronted with the fact that there must be a constant draft upon the aerial supply which is not replaced by animal exhalations. Seeking some other source, we know that in some places, such as the Grotto del Cane, in Italy, carbonic acid is emitted from the soil; active volcanoes, probably, exhale the gas on a larger scale; man, apart from his breathing, contributes some by the combustion of fuel in his manufacturing and domestic fireplaces, and for motive power, &c., generally; but, if we could take a bird's-eye view of the world, we should perceive that all these contributions are the merest trifles as compared with the demand. Finally, we must enquire what the aerial supply is, and we learn that, roughly speaking, there is only one part of carbonic acid in about three thousand parts of air, and that there are no data and no evidence implying that this proportion is decreasing. The puzzle,

therefore, is, How is the balance maintained? It is interesting, in this connection, to quote Prof. Huxley's *Physiography*, p. 84, in which he estimates the weight of solid carbon existing as a constituent of the carbonic acid gas in the atmosphere covering a square mile of land at about 3,700 tons, which suggests the question as to how long this supply would last for a square mile of dense forest of vigorous-growing trees, assuming that wood, as Prof. Huxley pointed out, "contains about half its weight in carbon." Having arrived at this concrete example relating to supply, it occurred to me to write to my friend, Mr. A. D. Webster, the well-known authority on forestry, to see if we could arrive at any definite data as to demand. He writes:—"The amount of timber added to a forest per year will, I find, vary exceedingly according to soil, age, and particular species of tree, but for all practical purposes it might be put down at 12,000 tons per square mile. Larch approximates 10,000 tons, and Oak 13,330, and this is worked out on the low basis of each tree producing 1 cubic foot per annum."

This means that the large areas of forest on the earth's surface entirely exhaust the supply of carbonic acid existing over at least three times their area each year, which, in its turn, means that, ignoring all other vegetation entirely, the entire atmospheric supply would become exhausted within a few years, even if one allows for partial restoration in the several ways above alluded to and the areas devoid of vegetation.

Personally, I find that the puzzle I started with has immensely increased in profundity, now that I have defined the two factors in it. In this connection I may mention an experiment I made. Two years ago I placed a small quantity of washed sand in a pickle bottle, hermetically stoppered with a glass stopper and a rubber ring, which I wired on after dropping a severed base of a Harts-tongue Fern frond on the surface of the sand. The base (a $\frac{1}{4}$ -inch section of the bottom of the stalk) had a tiny bud on it, which has sent up five or six fronds, each several inches long, very much drawn and attenuated, it is true, but yet alive, and fresh growth is showing. This bottle holds approximately 24 cubic inches of air, in which we may assume there was .008 of a cubic inch of carbonic acid gas, out of which, plus the little material in the base itself, these fronds have been fashioned. How is it done? Chas. T. Druery, V.M.H., F.L.S.

ORCHID NOTES AND GLEANINGS.

ODONTOGLOSSUM CRISPUM
FOWLERIANUM.

Our illustration (fig. 115) represents one of the most beautiful and distinct forms of the much-valued blotched section of the favourite *Odontoglossum crispum* from a plant in bloom in the collection of J. Gurney Fowler, Esq., Glebelands, South Woodford (gr. Mr. J. Davis). It has been named after its owner, the well-known chairman of the Orchid Committee of the Royal Horticultural Society, who is a keen collector of good and rare Orchids, and especially of *Odontoglossums*, which grow to perfection in the model cool Orchid house at Glebelands.

The reverse side of the flower is heavily blotched with claret colour, and it has a light

violet shade along the middle. The ground colour of the flower is white, but the greater part of the segments is taken up with deep ruby-crimson blotches of a peculiar brightness. The sepals have generally two very large irregularly formed ruby-crimson blotches, and some smaller ones of a purple hue. The petals are marked on about two-thirds of their area with large irregular, confluent ruby-crimson blotches, slightly divided in two or three places by narrow white lines, a thin purple line running from the base to the blotching in each petal, the margin being white. The lip is of good size, crimped at the margin, white, with a yellow crest and a pleasing marking of purple. The upper side of the column is tinted a deep reddish-purple. Distinguishing features in the flower are the clearness of its white ground and the glowing appearance of its rich ruby-crimson marking. Originally the plant belonged to Messrs. J. & A. A. McBean, of Cooksbridge, Sussex.

watched for, and already some very promising varieties have flowered, two of the best being the very distinct *O. crispum* Fergus (a flower of good shape and having a nebulous rose-purple centre to each segment), and another form with very finely shaped flowers, densely spotted with claret-red, and which is again expanding its flowers. Several others of the *O. crispum* Bonnyanum class, and with one large blotch in the centre of each segment, are in bloom; and of the white and rose-tinted typical form there are a number of very large flowered specimens, in each case the spikes being unrestricted, and bearing all their flowers, often to the number of 15 or 16, all expanded together. Examples of this kind sufficiently explain why *Odontoglossum crispum* is the favourite of most orchidists.

O. crispum is represented by thousands of fine plants, and other species and hybrids are in less quantity, but in equally choice condition. In bloom are some excellent *O. Adrianæ*, one with very large, broad-petalled flowers of a pale

vexillaria, including the varieties Queen Alexandra, superbum, and other rare forms. These are thriving and sending up spikes abundantly. In another division the Cattleyas and *Lælia* are accommodated, the specimens of *Lælia purpurata* being very strong and well set with flower-sheaths. The scarlet *Epidendrum O'Brienianum* covers the end of the house, and among other subjects in bloom were noticed Phaius Norman, Epiphronitis Veitchii, various Masdevallias, *Lælio-Cattleyas*, and on one side a representative selection of hybrid Cattleyas. The raising of hybrid *Odontoglossums* is a progress in these gardens, and little plants of various crosses were noticed, one of the most interesting being the already proved and handsome cross between *Odontoglossum Pescatorei* and *Cochlioda Noezliana*.

The warmer houses are reached through a lobby arranged as an ornamental rockery. Here in one house was found a very fine batch of the pure white *Cypripedium niveum* in bloom. These, with *C. bellatulum*, *C. Godefroyæ*, and others of the section, and their hybrids, seem to thrive well at The Shrubbery, and some promising crosses of these plants have been made, *C. Lawrenceanum Hyeaenum* × *C. bellatulum* album being one of which much is expected. In one of the houses is a large batch of *C. callosum* Sanderae, together with several *C. Lawrenceanum Hyeaenum*, and *C. Maudiae*, *C. Marshallianum*, and others; and of uncommon hybrids in fine condition were seen *C. Honoræ*, *C. Venus*, *C. Mrs. E. V. Low*, *C. Winnifred Hollington*; some good forms of *C. aureum*, including the still rare *C. aureum* Surprise, *C. Gravesiae*, and many other choice hybrids of *C. niveum*, some of which had not yet flowered. The next house was devoted to seedling *Cypripediums*, and a good batch of *C. Lawrenceanum* varieties in bloom. The most distinct is *C. Lawrenceanum Marjorie*, with which Mr. Ogilvie took the Second Diploma at the Royal Horticultural Society, June 12 last. The plant, which has since greatly improved, seems distinct from either *C. L. Hyeaenum* or the nearer ally, *C. L. Gratixianum*. It bears a noble, green-tinted flower, with a large white dorsal sepal bearing from the base emerald-green lines, the petals and lip having a very slight rose tint. The varieties of *Lælia anceps*, *Catasetums*, &c., are suspended in the corridor, and in the adjoining warm house is a small healthy lot of *Phalænopsis* and a good selection of the best varieties of *Dendrobium nobile*, and the showiest hybrids, some of which are in bloom. One of the best of the hybrids is the dark yellow *D. Thwaitesiae*, Veitch's variety, for which Messrs. James Veitch & Sons received a First-class Certificate in April, 1904, and of which there are several healthy little plants at The Shrubbery. In the intermediate house one side is devoted to *Cymbidiums*, in flower being several large plants of *Cymbidium eburneum* with many flowers, good *C. Lowianum*, a fine plant of the cream-white *C. eburneo-Lowianum* with several spikes, *C. Devonianum* in bud, two finely flowered *C. Schröderianum*, *C. insigne*, &c., together with some showy examples of the scarlet *Sophranitis grandiflora* and *Ada aurantiaca*, the yellow *Oncidium concolor*, *Odontoglossum triumphans*, and other species. In another house a specimen of *Cypripedium Rothschildianum* has a spike of four flowers, and many plants of *C. niveum* are also in bloom, with *Angræcum sesquipedale*, *Dendrobium Dalhousianum*, *D. Juno*, &c. In the other plant houses are Carnations, yellow *Richardias*, Crotons, and other decorative plants, and the garden outside will later be showy and interesting, by reason of its clever arrangement and the variety of the subjects included in it. J. O'B.

FIG. 115.—ODONTOGLOSSUM CRISPUM FOWLERIANUM.

(See page 277.)

The healthy condition of the *Odontoglossums* at Glebelands proves the success of the model Orchid house there, described in the *Gardeners' Chronicle*, December 15, 1906, p. 404, and which contains several excellent new features that might with advantage be copied by others who are not so successful in the culture of these beautiful plants. J. O'B.

ORCHIDS AT THE SHRUBBERY, OXFORD.

THE finest form of *Odontoglossum crispum* takes the leading place in the compact collection of F. Menteith Ogilvie, Esq., at Oxford (gr. Mr. Balmforth). Some years of experience in the culture of these favourite flowers has enabled their owner to provide quarters suitable for them in every respect, and a judicious weeding out of any but the finest forms has resulted in the present large collection being in the finest condition. Spotted forms are, of course, eagerly

yellow, spotted with dark reddish-purple, is most beautiful; there are also *O. loochristense*, *O. Rolfeæ*, *O. triumphans*, *O. Vuylstekei*, and many others. One plant of *O. crispum xanthotes* has two spikes of flowers ready to expand. These cool *Odontoglossum* houses are roomy, span-roofed structures, with central staging and side staging of open work. The moisture-providing surface is furnished by a low rockery on the floor beneath the stages, covered with green *Tradescantia* and other plants; and the close staging beneath the open one on which the plants are standing, and which is usually adopted for holding moisture, is now dispensed with. In these houses *Dendrobium Falconeri*, suspended overhead, thrives admirably, as do also *Vanda Kimballiana* and *Lycaste Skinneri*, varieties of which are making a good display in one of the houses; the variety *Ruby* has rich ruby-red petals and lip.

In another house is a good batch of *Miltonia*

EXHIBITION AT SASSENHEIM.

It is one thing to see bed after bed, row after row of Narcissus and Hyacinths in Holland, with a stork's nest on a long pole in the middle, and another thing to see the bulbs grouped as they would be in a private park or garden, with due reference to the surroundings.

FIG. 116.—SASSENHEIM: HYACINTHS IN FRONT OF THE MANSION.

It is one thing to see a vast glare of colour and experience an overpowering fragrance, and another to come suddenly on a bright patch of colour in front of a belt of leafless trees or ever-green shrubs. The directors of the great bulb exhibition at Sassenheim have adopted the latter plan. At present we do not know the details, but we can in a measure judge of the effect by the accompanying illustrations which we received from the Algemeen Correspondentie Bureau of Amsterdam.

The plan of the "Tentoonstelling" shows a park in the English style, with hundreds of beds appropriately arranged, and so contrived as to produce a picture and enable the connoisseur to examine and compare the components of each bed individually.

THE EFFECTIVE ARRANGEMENT OF BEDDING PLANTS.*

(Concluded from page 262.)

TYPICAL BEDS.

Let us take, for example, a row of five beds. In No. 1 plants with pinnate leaves might predominate amongst the taller subjects. No. 3 might be characterised by the presence of Japanese Maize, *Eulalia japonica*, &c.; whilst in bed No. 5 the use of broad-leaved plants such as *Ricinus* Gibsoni or *Wigandias* might be adopted. In beds Nos. 2 and 4, between those already mentioned, we could utilise flowering plants such as *Plumbagos*, *Streptosolens*, &c. Thus each bed would be distinct in its most prominent features from those next to it.

For the carpeting we might choose such plants of lower growth as would associate well with the taller species already decided on. *Celosias* may be well associated with the *Grevillea*, &c.; their somewhat stiff and upright habit will produce a pleasing, yet not too striking, contrast with the more graceful habit of the *Grevillea*. In bed No. 3, however, we should utilise

plants of a freer habit than the *Celosias*, in order to associate with the narrow, uniform leaves of the Maize above them, therefore we should do well to choose such plants as *Alonsoa incisifolia* or *Fuchsias*. In bed No. 5 we should also require plants of loose habit as a foil to the rather heavy foliage above them.

plants of striking habit in masses according to the form of their foliage. The first thing to be considered is the choice and situation of the beds. Groups of beds are most undesirable unless very widely separated. Widely spaced beds, in rows by the side of a straight walk, are better; but the ideal place for a sub-tropical garden is in some shady dell by the side of a stream or lake, where the walks are winding and where the beds can be irregularly disposed in front of a good background of trees and shrubs. The shape of the beds is also of importance. Thus nothing is more displeasing than a square or oblong bed filled with pinnate-leaved Palms or other plants of graceful habit. The straight outline of such a bed is altogether opposed to the appearance of the plants it contains, and utterly destroys any good effects they might otherwise have. For this reason a round or oval bed, or even a bed of irregular shape, is to be preferred to one of a rectilinear shape.

In the grouping of the plants, it is best to confine each bed to such as have similar habits, keeping those with stiff, narrow leaves, such as *Phormium tenax* and *Pandanus* apart from such plants as *Cannas*, *Ricinus*, &c. Flowering plants should be used very sparingly amongst the foliage plants, although beds of flowering plants in the neutral style are not out of place as accompaniments to the truly sub-tropical beds.

Fan-leaved Palms do not group well together, nor do they associate well with other plants in beds, except where the latter are very large. They are, however, amongst the best plants to be used as specimens on the lawn. In fact, Nature seems to have intended them for such situations, as in their native habitats they are generally found on grassy plains or in open forests, and, unlike the pinnate-leaved Palms, they seldom occur in dense bush. In a border of sub-tropical plants, however, the fan-leaved Palms may often find a place, as much greater freedom of arrangement may be followed here than when the plants are disposed in beds.

FIG. 117.—HYACINTH AND TULIP-BEDS AT SASSENHEIM.

SUB-TROPICAL BEDDING.

In the formal style of bedding the object is to arrange plants in uniform masses with regard to their colour only; in the natural style, the object is to produce harmony of colour combined with contrast of form; whilst in sub-tropical bedding the object is to arrange large

This applies also to flowering-plants, and also to variegated-leaved plants, which may be used much more freely in a border than in a bed.

Plants specially suitable for sub-tropical bedding are those with characteristically graceful or massive foliage. A. W. Proudlock.

* A paper read before the members of the Kew Gardeners' Mutual Improvement Society by Mr. A. W. Proudlock.

TREES AND SHRUBS.

RHODODENDRON INDICUM (AZALEA) AT LEONARDSLEE.

THE collection of these plants in the open garden at Leonardslee is very rich in varieties, and there are in addition to named sorts hundreds of choice seedlings, the whole making a brilliant display during May and June. These plants require to be kept clean, and free from the presence of tree roots. They should be top-dressed annually, if possible, with a mixture of good leaf soil and cow manure, but, under any circumstances, they should not be left longer than three years without receiving additional food in the shape of a top-dressing. Azaleas should not be planted deeply for they are surface rooting, but they should be planted as firmly as is possible. Sandy loam with a mixture of flaky leaf soil forms an ideal rooting medium, and a top dressing as before stated should be given the second year after planting. The plants need little in the way of pruning, but long, unshapely growths should be cut out, and if the pruning is performed when the plants are in flower, the shoots removed can serve a useful purpose to help to furnish the vases indoors. Azaleas can be shifted any time during the winter and up to the end of March, with every hope of success. Plants may easily be raised from seeds, and seedlings may be flowered in this locality within a period of four years from the time of seed sowing.

PHOTINIA SERRULATA.

IN answer to H. W. (p. 223), respecting the hardness of this shrub, the frost did not seriously damage our plant, and it was after the severe frost of March 8 that I took sprays to the Royal Horticultural Hall. We have lost very few plants from the effects of frost this season. Amongst those that have suffered most is *Dracena Parryi*, and I am afraid some very fine plants of this tree will succumb; they appear to have been frozen about 8 feet up the stem. *Calistemon floribunda* has been injured at the tip of a few growths, but this is not to be wondered at, considering the trees made very late growths last autumn and developed a second batch of flowers. *Opuntia glauca* has been much injured, *Eugenia apiculata* has also suffered considerably, but *Eugenia Ugni* is unhurt. One large plant of *Fabiana imbricata* has several branches injured and this specimen was given protection by Heather and Bracken. An unprotected plant of this species situated a few yards away was unharmed. W. A. Cook, Leonardslee Gardens, Horsham.

JASMINUM PRIMULINUM.

THE severe winter here has not interfered with the flowering of this lovely species. It has been a sheet of yellow for the past month. The leading shoots made last summer have been crippled a little at the points, otherwise the plant is unhurt. The flowers are mostly produced from short, twiggy shoots made in the previous year, but as our plant was only put out a year ago I cannot say much about the treatment it requires, but probably if treated similar to *Chimonanthus fragrans*, by having the shoots spurred back moderately immediately after flowering, this would prove satisfactory. The plant occupies a very warm position. J. Mayne, Bilton, Devonshire.

NURSERY NOTES.

FERNS AT H. B. MAY & SONS', UPPER EDMONTON.

THIS firm also owns two other large nurseries: the one at Tanner's End, Edmonton, and the other at Chingford, but it is to the older nursery at Dyson's Lane, Edmonton, that the following remarks apply. Here it is that the choicer Ferns are housed. Many of the most popular varieties of market Ferns were first sent out from this nursery. Looking back, I remember the time when *Pteris serrulata cristata compacta* first

attracted attention, and this still retains favour with many growers, but it is not so extensively grown now as formerly, being superseded by *Pteris Wimsetti*, which was also sent out from this nursery, and which is one of the most popular market Ferns at the present time. *Pteris cretica Mayi* had a long run of favour, but it now has a rival in *Pteris Alexandra*, which also originated at Dyson's Lane. Many other old favourites, if not raised by him, were first brought into the market and popularised by Mr. May, who is one of the pioneers of Fern growing for market. *Adiantum* have given no novelties in recent years, but those raised in these nurseries a few years ago still remain popular. From one batch of seedlings several very distinct varieties occurred, and of these *Schneideri*, *tenellum*, and *Hemsleyanum* each received an award from the Royal Horticultural Society; later, *Scutum ramosum* and *fasciculatum* were added. This nursery is also noteworthy for the raising of some of the most distinct varieties of *Aspleniums*, these including *Mayi*, *Herbeti*, and *Drueryi*, which have all been honoured with awards from the Floral Committee of the premier society.

Among *Davallias*, Mr. May's *D. Fijiensis robusta* is now extensively grown, and *D. r. gracillima*, and *D. r. magnifica* are other pretty varieties from the same source. *D. effusa* and *D. decurrens* also originated here. And the genus is represented at Edmonton by a large number of choice species, including the charming little *D. alpina* and *D. parvula*.

Gymnogrammas, including all the best species, are well grown. Varieties raised by Mr. May include *grandiceps superba*, *Mayi*, *Cordreya*, *Reginae*, *Alstoni superba*, &c.

Lomarias have been productive of many distinct varieties, these being chiefly raised from *L. ciliata*. *L. Hermineri* was very bright in colour at the time of my visit (November). *L. attenuata* is another species with tinted fronds. Of *Nephrolepis* a number of very pretty varieties have originated in this establishment, *N. exaltata superba* being one of the prettiest of all. *N. e. Mayi* is very distinct, and *N. e. crispato-congesta* very pleasing when small. *N. e. superba* is a fine variety. *N. e. canaliculata* is one of the most recent introductions, and this is a remarkably distinct kind that produces a hairy growth at the extremities of the pinnæ. Several other crested varieties of *Nephrolepis* were noted, and all the best of the American sorts are grown. Of these *Whitmani* appears to be a great improvement on *Piersoni*. *N. elegantissima* recently gained a First-Class Certificate from the Royal Horticultural Society. It is a neat and compact plant, with a wonderful development of the additional lobes of the pinnæ. *N. Barrowsi* is another *Nephrolepis* from America which looked promising. *N. e. Scotti*, the compact form of *exaltata*, as grown here, appears a very useful Fern, but the old favourite (*exaltata*), which makes the best basket Fern we have, is most extensively grown. More progress has been made with this genus, both in regard to improved varieties and in popularising them as market plants during the last few years, than has been done with any other Ferns. In *Polypodiums* some beautiful varieties have been raised: perhaps the most prominent is *P. Mayii*, the plumose form of *glaucum* or *sporocarpium*. This Fern, like many others with extended growths, has failed to produce spores, yet large quantities have been propagated. It may possibly never pay to grow this variety for market, but it should be included in all collections. *P. Schneideri* is another beautiful Fern, and from this Mr. May has some sports. A new variety from America, *P. angustatum*, is a Fern of great promise. Particularly interesting and pretty were those with small fronds and spreading rhizomes, growing on moss-covered tree stumps. The *Platyceriums* are well grown, and seedlings of *P. grande* were doing well, also *P. angolense*, *P. Veitchi*, *P. madagascarense*, a distinct and new introduction, *P. alcorni*, and its

varieties, of which *divergens* may be considered the best form. In America the *Platyceriums* have been popular for decorative purposes, and if growers persist, they will soon be appreciated in this country for the same purpose, for they last better than almost any other Ferns.

Plants of *Pterises* seen included a large number of Mr. May's own raising. A batch of *P. Summersi* was very pretty. *P. Childsi*, another plumose variety, was well grown. I find there are 30 varieties of *Pterises* of Mr. May's own raising, and of these 18 have gained awards from the Royal Horticultural Society. I will conclude by mentioning the *Selaginellas*, which are represented by something over 50 of the best species and varieties. Interested Visitor.

KEW NOTES.

THE GREENHOUSE.

[SEE SUPPLEMENTARY ILLUSTRATION.]

AT this season of the year the pot plants in this house, No. 4, are changed more frequently, perhaps, than at any other. Whilst a number of subjects remain in the house in a decorative condition for several months, a few are valuable for about a week only, especially when such bright weather as at Easter last is experienced. Others, particularly species of forced trees and shrubs, are attractive for a fortnight or three weeks.

The section of plants known as "hard-wooded" are strongly in evidence at the present time. A large bush of *Eriostemon myoporoides*, on which the first flowers opened in December, is still carrying a goodly number of flowers. The pretty pink *Boronia fastigiata* (syn. *polygalaeifolia*) is not fragrant like *B. megastigma*, but it is more showy, very free-flowering, and eminently suitable for pot culture. *B. heterophylla* also deserves mention in passing. A small group of *Olearia stellulata* in 6-inch pots is well in flower. It is worthy of more extended cultivation as a pot plant for the cool greenhouse, whilst it proves hardy in some parts of the country. *Ericas* are represented by *E. persoluta alba* and *rubra*, *E. candidissima*, *E. Wilmoreana*, and *E. Cavendishiana*. The scarlet-flowered *Correa cardinalis*, although a rather difficult subject to grow, is worthy of the extra attention it needs on account of its flowering freely, and remaining in flower, as it does, for so long a period. *Correa speciosa major* makes a better growth than the last-named: its flowers are also pretty, but not so striking as those of *C. cardinalis*. *Polygala myrtifolia grandiflora* (syn. *Dalmaisiana*) is well represented in the house, there being both large and small specimens. *Helichrysum* (syn. *Aphelexis*) *humile*, var. *purpureum* continues for a considerable time in flower; the shining, silvery leaves also render the plants additionally attractive. The large plants of *Acacia armata* are past their best condition of flowering, but a few in small pots serve to prolong the season. *A. hastulata* and two large specimens of *A. pulchella* are also worthy of mention. Two plants of *Audouinia capitata*, about 18 inches in height, are a mass of purple flowers, which, though small, are very numerous, and are arranged in crowded terminal heads.

Senecio auriculatissimus, sometimes called the Yellow Star *Cineraria*, is a notable feature. It is readily raised from seeds or propagated by means of cuttings, and the old plants may be grown for several years. Trained around three or four stakes in the shape of a balloon they are very pretty objects. *Dimorphotheca Ecklonis* is just now one of the most pleasing plants in this house when the sun is shining. The ivory-white ray florets, tinted with purple on the outside, are a fitting setting to the violet-coloured disc florets. A group of the scarlet-flowered *Salvia splendens* mixed with *Lilium longiflorum* forms a rich bank of colour. The *Salvias*, after flowering in this house last

autumn, were placed in an intermediate house in which they afterwards developed plenty of flowers. A brilliant scarlet colour such as furnished by this plant is always welcome.

The genus *Arctotis* is represented by several species. *A. aureola* has rich orange-coloured flowers. The ray-florets of *A. aspera* are white on their upper surfaces and tinted with pink beneath. The variety *arborescens*, as the name indicates, grows much more vigorously than the type; several of the plants at Kew are 8 feet or more in height. The ray-florets of this flower are also white above; the underside, however, has the pretty pink tinge more marked, rendering the lower side of the flower prettier than the upper. Being tall in growth,

certainly the most pleasing shade. Two large plants of a particularly good form of *Alonsoa incisifolia* are covered with rich red flowers. This is a glabrous, greenhouse shrub, with flowers disposed in terminal racemes. It has been in flower at Kew for several months past. Plants can be readily raised from seeds, but when a superior variety such as that in the greenhouse under notice is possessed it should be increased by means of cuttings.

A group of the rich yellow Canary Island Buttercup [*Ranunculus cortusæfolius*] must not be passed by without mention. An old plant, fully 4 feet high, is surrounded by young plants 2 feet to 3 feet in height that were raised from seeds last year. One of our British wild plants,

THE COUNTRY GARDEN.

IN striving for a beautiful garden there is one thing that we cannot afford to overlook, and that is to make of it also an interesting one. Of course, every garden is, in a sense, interesting, but, just as some plants are more beautiful than others, so there are some of greater interest; and, if we want to secure an interesting garden, we must see to it that a full proportion of these finds a place. For instance, we might name as constituting especial interest the presence of those forms of blossom that are but sparsely represented in the flower-world, for such will always attract attention. Thus, the salver-shaped blossoms are ever with us, but take the *Dicentra spectabilis*, to what can you compare that graceful and wonderful shape of flower? It stands out among other plants as a beautiful, a rare, almost an idealised form of blossom. Or, again, some curious or unusual habit of growth—even a quaintly-formed seed vessel or fruit may constitute a plant's claim to be grown as a subject of especial interest. Such a plant as *Carlina acaulis* is thoroughly typical of an unusual habit of growth—a solitary flower to crown the elongated foliage, and that, too, of not common texture, or colouring; a silver flower, shall we call it? Of a plant producing a noticeable fruit, *Podophyllum Emodi* may be cited. For a good many reasons I look upon this as a desirable plant for the garden, beyond its merit as an interesting plant: its flowers, produced in May, are extremely pretty, and its highly-coloured fruit is ripe sufficiently early (by the end of July) to make the place again decorative during the summer months, and it flourishes in the semi-shade, a matter of considerable importance, I think, and decidedly a merit not to be overlooked. Unusual in habit of growth—yes, and striking too—is *Lewisia rediviva*. When in flower it is one of the unforgettable things, and it is not really difficult to grow it to perfection if established in gritty loam in the rock-garden in some sunny aspect, with a slab of stone on either side of it.

As touching both the beauty and the interest of the garden there is a consideration that seems to me worthy of careful thought and attention, and that is the need to secure to the full value the decorative effect of blossom in great variation of height. Take a garden poorly planted so far as flowering trees and shrubs are concerned, and compare it with one in which at early summer there is blossom from the top-most branch of an old *Acacia* tree down through the lesser heights of *Lilac*, and *Laburnum*, and *Guedres Roses*, and so descending to the plants in the perennial borders, the *Pæonies*, and *Oriental Poppies*, until it reaches well nigh to the ground level in the *Pansies* and the creeping, trailing things. Then, again, at a later season, how much fuller of blossom does a garden appear when the eye finds colour at the height of a bold group of *Hollyhocks* than it does if blossoms stop short at the height of *Phlox decussata* and early-flowering *Chrysanthemums*. I recently came upon a paragraph in which the writer was at the pains to praise the dwarf annual *Sunflowers*, and to regard them of greater worth by a good deal than the older and taller varieties. I may be wrong, but it seems to me this writer did not realise how valuable these tall, bold *Sunflowers* are in the garden—characteristic, handsome, distinctive, and for their very height filling a need, holding their own, and likely to hold it, as the new dwarf varieties will never do. To raise the colour level in a border to 6 or 8 feet is a vastly different thing from stopping short at three or four, so far as decorative value is concerned, and especially for distant effect.

There are some of our perennial plants that must be looked upon as indispensable, simply because they flower when they do. There are short periods in the midst of the flower year when there are, as it were, pauses: one of

FIG. 118.—SOPHRO-LÆLIA "PHROSO SUPERBA" (L. JONGHEANA X S.-L. LÆTA ORPETIANA): COLOUR OF FLOWER MAUVE-CRIMSON, WITH ORANGE DISC TO THE LIP.

(Awarded R.H.S. First-Class Certificate on April 16 when shown by Major Holford, see p. 259.)

the reverse of the flower is more often seen than the top. At present there are only one or two flower heads open on *A. revoluta*, but plenty of buds are visible. The chief points to remember in growing *Arctotis* are that the plants require during the winter sufficient heat only to counteract frost, a sandy, well-drained soil, and water sufficient to prevent them from flagging.

A number of plants of the flesh-pink Stock "Beauty of Nice," 2 feet in height, interspersed amongst a group of double Wallflowers, together pervade the air with their delightful fragrance. *Nicotiana Sanderae* is to be seen flowering profusely in many shades of colour, pure white, deep purple, rich red, &c. The last-named is

Fritillaria Meleagris (the Snake's Head Fritillary), finds a place. The flowers are white, pale purple, and deep purple. The bulbs were potted last autumn in company with such plants as *Iris reticulata* and kept in a cool frame, from which frost was excluded till the flower buds appeared. The new yellow *Coreopsis Grantii* gives promise of being a useful addition to our winter and spring-flowering greenhouse plants. Although *Buddleia asiatica* has lately been extolled very frequently, the more the plant is seen the more does it impress one with its worth. The plants in this house have been in flower for a period of between seven and eight months. D. D.

these comes with the advent of June. The late spring-flowering plants are passing, and the summer flowers are coming, but, as yet, scarcely come. Buds and promise everywhere, but all the same this slight pause. The Lupines fill the gap: it is their flowering time. Every year, as it comes round, the value of them is emphasised, as I find them in great quantity in the garden until I have come to set quite an especial value on the Lupines among the hardy perennials, and I am not thinking so much at the moment of the tree Lupines as of such varieties as *L. polyphyllus* and its different strains, *L. perennis*, and *L. subcarneus*. The weeks go by, during which the Delphiniums and early-flowering Campanulas, *Buphthalmum*, and other perennials are in their full beauty. Their day is over—again comes a perceptible, though a short, pause. But this pause is the flowering time of *Achillea ptarmica* fl. pl., so that it, too, I have come to regard as one of the indispensable plants for the summer garden. It flowers over so long a period, and it so charmingly fills the gap, that it seems to me to be well worthy of a choice position and good cultivation. It does well in ordinary garden soil, especially if it be of a loamy nature, but I have always found that it flourishes in positions that are not too hot and dry. This is easily accounted for, as the roots are close under the surface, and the plant does not thrive in too hot an aspect during long droughts on that account. The variety known as "Snowball" is excellent. *Practical Gardener*.

The Week's Work.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower to Sir Trevor Lawrence, Bart., Burford, Surrey.

Odontoglossum house.—At the coolest end such species as *Odontoglossum Edwardii*, *O. ramosissimum*, also *Oncidium tetracopis*, *O. loxense*, *O. serratum*, *O. monachicum*, *O. macranthum*, and its distinct variety *nanum* thrive well. The new growths are now making considerable progress, and several species have their flower-spikes well advanced. Afford these plants plenty of water at the root, or the pseudo-bulbs will, in some cases, shrivel under the strain imposed by the growth of the flower-spikes and consequently fail to expand some of their flowers. The aerial roots of the rambling *O. æbrinum*, and those of the new *O. Clæianum* should be sprayed over several times each day whenever the weather is bright. *Lycaste Skinnerii* and its varieties also thrive well in this house. As the plants pass out of flower, let them be examined in order that those needing re-potting may be given attention. They succeed well in a well-drained compost of fibrous loam, peat, and sphagnum-moss. Growers should be careful not to bury the base of the young growths too low in the soil, or they may decay. For several months after root disturbance water should be applied sparingly, reserving an abundant supply until new roots are seen pushing through the compost and growth is luxuriant. During the growing season these *Lycastes* are sometimes attacked by a small species of red spider, therefore it is advisable to wash the leaves occasionally as a preventive.

In the intermediate house plants of *Cœlogyne cristata* and its varieties are starting to grow. Any overgrown specimens may now be divided and re-potted, and plants requiring more room for extension should also be attended to at this season. Pots or shallow pans are suitable for *Cœlogyne*s; but whatever receptacle is used it should be well drained. A compost of peat, fibrous loam and sphagnum moss will suit the plants, adding sufficient small crocks to keep it porous. Specimens which have been broken up and re-potted require very careful treatment; the pseudo-bulbs usually shrivel slightly after root disturbance, but it is not advisable to saturate them with water at the root in order to keep them plump, it being better to spray them overhead occasionally and to shade them from all direct sunshine. Plants of *Miltonia vexillaria* that are growing well and developing flower-spikes should be copiously supplied with water whenever the compost appears dry. Small, weakly plants should have their flower-spikes removed immediately they appear. The distinct

hybrid, *M. Bleuana*, and its variety, *nobilior*, are now in bloom. Do not spray the flowers, and they will then remain fresh for a long time. The Brazilian *Miltonias*, as *M. spectabilis*, *M. Moreliana*, &c., are growing freely, and will require to be kept moist at the root. Prevent over-wetness or the young growths will rot and disease ensue in the bulbs.

Odontoglossum citrosimum has now passed through its resting season, and no amount of dryness at the root will cause plants to flower that have not been properly rested. Let these plants be suspended well up to the light in the Cattleya or Mexican house, and kept well supplied with moisture all through the growing season.

THE HARDY FRUIT GARDEN.

By J. MAYNE, Gardener to the Hon. MARK ROLLE, Bicton, East Devon.

Gooseberries give every promise of yielding a full crop, but a severe frost has been known to destroy most of the tiny fruits even later than this date; therefore, it would not yet be safe to say that they are out of danger. This is not all, for the Gooseberry caterpillar or saw-fly frequently attacks the bushes, and if left unmolested for long, completely riddles the foliage, which naturally causes the fruit to fall. If the pest is taken in hand immediately the larvæ can be seen, we can soon clear the bushes of this pest; but as the eggs are laid on the under side of the leaves, an observant eye is necessary to detect them before much damage is done. Examine the bushes, therefore, at short intervals. By persistent hand-picking every other day or so for a week, we are always successful in saving the bushes from suffering much injury. It is a tedious job, but it is time well spent. Finely sifted lime and soot dusted over the bushes when the leaves are wet has been a success, but if the fruit is of much size when this is done, they will require to be washed before they are sent to the kitchen. Hellebore powder has also been effectual, but as this is poisonous, much care is required that the fruit is made perfectly clean before using. Paris Green and London Purple have been used with more or less success, but both are extremely poisonous.

Apple trees and their enemies.—The two most dreaded pests are the Apple blossom weevil and the Apple sucker. The former appears early in May as the weather becomes warm, and attacks the flower buds before they are fully expanded, causing the petals to turn brown. These, if minutely examined, often contain the yellow pupa of the weevil, and on comparatively small trees this may be easily exterminated by the hand, but on large trees this would be out of the question. It may be hoped that winter spraying will eradicate the pest if carried out periodically. The Apple sucker, as its name implies, imbibes all the juice it can get from blossoms and buds, causing the same to decay and fall off. The small holes in the flower buds and petals denote the presence of this pest. Spraying with quassia extract at about 4 p.m. in the day will, to a certain extent, lessen the attack, the bitterness of the wash making it unpalatable to this pest.

Protection of blossom.—The decided change to milder weather will be welcomed by all fruit cultivators, enabling them to dispense with the protecting material over Apricots and Plums; as well as Cherries growing against warm walls. Where glass copings are in use these may be left for another week, and it is best to remove part at a time in case a check may be caused to the trees. There need be no hurry about the Peach wall, unless very warm weather sets in, although the leaves which are clean and healthy will now shelter the small fruits more or less from late frosts and cold storms.

Thinning and disbudding.—Continue the removal of superfluous shoots on Apricot and Peach trees, and the thinning out of the fruits, but do not thin Peaches and Nectarines severely at this date. Should the black aphid be present, the trees may be safely syringed with quassia extract on a mild afternoon, washing this off next morning with clear water before 9 a.m., remembering that foliage and fruit alike are both tender as yet, so that weak doses only ought to be applied, and these should not be applied with much force from the syringe.

FRUITS UNDER GLASS.

By ALEXANDER KIRK, Gardener to J. THOMSON PATON, Esq., Norwood, Alloa, Clackmannanshire.

Muscat Grapes which have a fairly good "set" and are swelling their berries very evenly should have the atmospheric temperature raised to 65° Fahr., or even 70° on very mild nights. Close the house early in the afternoon when the thermometer registers 90° of sun-heat. Keep the atmosphere of the house moist by damping the paths and borders in the morning and again at closing time. Admit air by the top ventilator only. Open the ventilator very little in the morning as soon as the inside atmospheric temperature is over 70°; admit more air as the day advances. Avoid opening the bottom ventilators thus early in the season if possible, as this would favour the spread of red spider and tend to produce leaf-scorching by causing too rapid evaporation. Before thinning out the berries, tie up the shoulders of the bunches with small strips of matting. When thinning, run a small strip of matting through the bunch to enable the operator to hold it in position. Always commence thinning from the point upwards, first cutting out all the small and stoneless berries; do not thin too severely. Muscat should not be thinned until it can be detected which berries will fail to produce "stones," it being desirable to remove all such berries. Pinch the sublateral and tie in young growths wherever there is space and light for them. If the borders are found to be dry, remove the mulch to one side, apply a good dressing of a fine-grade vine and plant-food and afford a plentiful supply of tepid water.

Black Hamburgh and Madresfield Court Grapes.—Late vines now coming into flower must have an atmospheric temperature of 70° at night during mild weather. Close the house early in the afternoon when the temperature is 85°. Keep the atmosphere dry. Admit air cautiously, and only by the top ventilators. Give the cane a good shake with the hand at mid-day to disperse the pollen throughout the house. Black Hamburgh sets its flowers so easily that the vines do not need so much attention in this respect as is given to many other varieties.

Late vines of the varieties *Lady Downes*, *Lady Hutt*, &c., now breaking strongly, must have the points of the shoots pinched at two leaves beyond the bunch and the sublateral pinched at the first leaf. Do not be too hurried in tying down the shoots to the wires, as they are so easily turned out of their sockets. Damp the ground surface twice daily and keep the atmosphere fairly close. Maintain the atmospheric temperature at night at 65°, and at 85° by day, closing the house early in the afternoon.

Young vines that were planted out in March will now be making good growths. Pinch the leading shoot when it has made growths 4 feet in length, and afterwards allow it to run to the top of the house, pinching all laterals beyond the first leaf, unless the vines are weak, when they must be tied in. Admit air freely that the vines may make hardy and short-jointed growth. Maintain a humid atmosphere. Close the house early with sun-heat.

PUBLIC PARKS AND GARDENS.

By W. W. PETTIGREW, Superintendent of the Parks and Open Spaces in the City of Cardiff.

Bowling greens and tennis courts.—The beginning of May is the usual time for the opening of bowling greens and tennis courts. The provision of ground for the purposes of bowls and tennis in public parks is not so general as might be expected. From a number of enquiries, however, that we have recently received from other towns, the popularity of these pastimes—especially bowls—seems to be increasing, and park authorities are apparently awakening to the fact, and are trying to meet the demand for proper facilities. It is now generally recognised that public bowling greens or tennis courts, to be of the greatest value to the greatest number, must be so managed that everyone playing upon them should pay a small fee for doing so. The advantage of this, from the standpoint of the public, is that all the apparatus needed for playing the game is found for them. Persons who cannot afford to pay for membership of a club, or purchase the requisites for the game, can on such greens get ample recreation and amusement for a very small outlay. From the administrative point of view this system of management means better control, and, further, that as a revenue is derived from the greens, a

great deal more care and attention can be bestowed upon their upkeep, resulting in greater satisfaction being given to those patronising them. Generally speaking, a free bowling green or tennis ground is only of use to a select few or a club, whereas the grounds where small fees are charged are practically open to all comers.

Necessary rules.—Public greens, to be a success, have to be managed under a set of good and comprehensive rules, which should always be strictly enforced. The rules must be of a two-fold character—the first having as its object the protection of the ground and the apparatus belonging to it; the second the convenience and help of the public using the ground. In the first case every precaution must be taken to prevent excessive wear and tear of the greens, hence it is necessary to stipulate that none but actual players shall be allowed upon the ground; that all players must use indiarubber-soled boots or shoes; that no umbrellas or walking sticks shall be taken on the greens; and, lastly, that no play shall be allowed during unfavourable weather.

Regulation of players.—To enable the greatest number of persons to use the ground at one time, eight players in the case of bowls and four players in the case of tennis should be the recognised number of a rink or court. No player should be allowed to play for more than one hour at a time if others are waiting to use the ground. The charges made for the use of bowls vary in different towns, but are from 1d. to 2d. per hour for each person. For tennis courts 2d. or 3d. an hour is charged per person, and if rackets and balls are supplied each player pays an extra fee of 2d.

THE KITCHEN GARDEN.

By WILLIAM H. HONESS, Gardener to C. COMBE, Esq., Cobham Park, Surrey.

Brussels Sprouts.—The first batch of these that were sown early in February will now be large enough, and should be sufficiently hardened for planting out in their permanent quarters. Plant them in drills drawn at from 2½ feet to 3 feet apart, and put each plant at 2½ feet distance from its neighbour. Ground which has just been cleared of late Turnips, and well manured, would provide a good site for this crop.

Celery.—The earliest plants will soon be large enough for planting out in the trenches, and they may be put out as soon as they are considered to be in a fit condition. If the plants were allowed to become starved, or overcrowded before transplantation, they would be more liable to bolt than those given timely attention. Those plants intended to form the main crop will now be ready for pricking off into a cold frame. Employ good, rich soil, with a good layer of decayed cow manure at the bottom. The depth of the combined compost need not exceed 4 or 5 inches, but care must be taken to keep it in a moist condition. When the time arrives for planting them in the trenches, the young plants will be furnished with an ample quantity of roots. These should be disturbed as little as possible in order to avoid causing the plants unnecessary check. If a liberal sprinkling of soot is applied both at pricking-out time and again when the plants are put into the trenches, it will act as a preventive against the Celery fly, which is often troublesome soon after planting time and again after the work of earthing-up has commenced.

Runner and French-climbing Beans.—Sowings should now be made in the open ground of such excellent varieties as Hackwood Park Success and Scarlet Emperor. The former is a good standard variety, and the latter, of more recent introduction, is one of the finest novelties ever introduced. It is advisable to afford the plants some protection as soon as they appear above ground, and it may be required until the end of May. Much bitter disappointment has been experienced during the last two or three years owing to this type of Bean having been cut off by the severe frosts late in May. By sowing the seeds thinly in boxes, and cultivating the young plants in a cold frame, such disappointment may be averted, for strong plants may be thus raised, which will be ready for planting out as soon as all danger from frost is considered to be past. With ordinary care Beans may be lifted and transplanted most successfully.

Globe Artichokes.—There is still time to plant suckers of these, if this work has been delayed. From plantings made even late in May, that have been mulched and kept well watered; we have had a good supply of "Chokes" late in the autumn, long after plants that have been fruiting through the summer have ceased to be productive. It being usual to allow these plants to occupy the same site for several years in succession, the ground should receive a thorough preparation previous to planting. Put out the plants at distances of 4 feet each way.

PLANTS UNDER GLASS.

By J. G. WESTON, Gardener to H. J. KING, Esq., Eastwell Park, Kent.

Chrysanthemums.—Re-pot the plants before the roots become pot-bound, otherwise they will suffer a check to growth. The compost should consist largely of good turfy loam, adding leaf-soil and sand. Make the compost firm about the roots, for loose potting, especially if the soil is very rich, tends to encourage rampant growth, instead of the sturdy, short-jointed shoots so much desired. Return the plants to the frame, and admit air at all times, keeping the lights off altogether on suitable days. If it is imperative to place some of the plants outside, arrangements should be made to cover them when necessary with spare lights, boards, and mats in order to protect them from hailstorms and frosts.

Climbing plants in houses.—Examine these at regular intervals, not allowing the new growths to become entangled, but thinning them out and pinching them as required, tying in a sufficient number to furnish the desired space, and if head-room permits, allowing the lateral growths to droop downwards in a natural manner. Stephanotis, Dipladenias, Cissus discolor, and similar climbers will thus show to better advantage than if trained stiffly along the wires. Young plants should be potted on before there is any check to growth, while established plants should be stimulated by an application of some approved fertiliser. Strong growers like the Allamandas require frequent and abundant supplies of water. Insect pests must be rigorously combated, or they will soon become an intolerable nuisance. Bougainvilleas should be given an exposed sunny position. The plants flower much better from well-ripened wood of the previous year, and the bracts are of a much better colour than when grown in comparative shade.

Caladiums.—Re-pot these as required, giving liberal shifts to any that it is desired to grow into large specimens. Use a rich, porous compost, and provide the pots with perfect drainage. Caladiums require stove temperature, and the syringe should be used freely to maintain a damp atmosphere. Keep the plants well up to the light in order to develop the beautiful marking of the foliage, but provide shade during the hottest part of the day. *C. argyræ* and *C. minus erubescens* are two useful varieties of dwarf growth for the edging of decorative groups or stages in warm plant houses. For such purposes, pots 3 or 4½ inches in diameter are large enough for these varieties.

Gloxinias.—Afford plenty of room, and keep well up to the light the early plants now showing bloom. If the pots are filled with roots, apply a gentle stimulant. Re-pot the batches of seedlings as required.

THE FLOWER GARDEN.

By A. C. BARTLETT, Gardener to Mrs. FORD, Pencarrow, Cornwall.

Wall-plants.—The shoots of Clematis require to be frequently regulated or most of the bloom will be massed at the top, leaving the lower portion bare. All wall-shrubs of doubtful hardiness should have their growths kept thin so that they may become well ripened and better able to withstand a hard winter. Roses will need spraying or syringing to kill green fly. Soapy concoctions stain the walls and leave unsightly deposits on the leaves. Quassia chip water has neither of these defects, and not only kills the fly, but leaves its bitter property behind, which is unpalatable to the next generation of aphids. Occasional searches should be made for the Rose maggot, squeezing the curled leaves, and removing any flower buds which have been pierced.

Camellias.—Established bushes should be afforded every three or four years a top dressing, which may consist chiefly of fibrous loam, with a little leaf-mould, sand and bone-meal added. In the other years a dressing of artificial manure should be given. The Camellia is harder than many people imagine, and, in a favourable flowering season, such as the present one, good-sized bushes in the open are a revelation. An ideal spot for their culture would be a gentle slope to the south or south-west, sheltered from rough winds. The semi-double and single varieties are better than the double forms for culture out-of-doors, as the double flowers hold the rain and quickly decay. *Lavinia Maggi*, *reticulata*, *japonica*, *Donkelaar*, and *Mathotiana* may be recommended. The best time to put out pot plants is just as they have finished their growth.

Wild garden.—While, on the one hand, ostentatious tidiness is undesirable, this part of the garden must not, on the other hand, be allowed to degenerate into a wilderness. All coarse weeds must be hooked out, and vigorous growers—especially those of the *Rubus* genus—which are occupying too much room must be restricted. This is best done by cutting away whole branches or growths, rather than by pruning. Bulbous and shrubby plants which have been forced and are not required again for culture indoors may be planted in the wild garden, taking care not to leave more evidences of soil disturbance than can be avoided.

Bedding plants should now be removed to cold frames, affording them as much air by night as well as by day as can be safely given, so that the plants may become thoroughly hardy before being planted in the flower beds. At first all necessary watering should be done in the mornings; if the surroundings are fairly dry a low night temperature is less harmful than when the atmosphere is charged with moisture.

THE APIARY.

By CHLORIS.

Virgin queens.—One means the bee-keeper may employ for the cutting down of expenses, with very little degree of danger to efficiency and success, is to purchase virgin queens. It is very expensive to buy fertile queens, while the virgins may be bought at a very low figure, for so many of these can be raised with little difficulty by the queen-raiser, but the fertile ones are fewer. The reason few virgins are bought is because the purchaser is afraid that they will not be mated. There need be no doubts on this head if they are purchased from a reliable source. No queen-raiser who hopes for success in business would dream of sending out those queens that have passed the period when successful mating can be expected. The one thing that should ensure the success of the system is that virgin queens are so very easily accepted by a queenless colony if care be adopted. The queen to be introduced ought not to be more than two or three days old if complete success is to attend the effort.

How to make nuclei with virgin queens.—Take about three combs from established colonies, such combs as contain sealed brood, but neither eggs nor larvae from which queens could be raised. The combs, with their adhering bees, taking care there is no queen among them, should be removed about mid-day and placed in a hive at a distance as far as convenient from the old stand, and the entrance must be closed. In the evening the entrance may be cautiously and noiselessly opened, and the box containing the new sovereign may be placed at the opening and she will go among the cluster almost unobserved. I advise noon for the removal of the combs because most of the field bees will be from home. When many queens are hatching, if a cage be placed over each ripe cell, many valuable young queens may thus be secured from one's own apiary and utilised in the same manner, if the bee-keeper purposes increasing his stocks.

Dysentery.—Bees suffering from this trouble should be changed to a clean hive and be given fresh quilts.

Robbing.—At this season, when there is little nectar to be gathered, bees from strong colonies will often attack those that are weaker; therefore, keep each colony as strong as possible, and spill no syrup about the hives. Should there be a tendency to robbing, cease feeding for a little time, and close all entrances, so that one bee only may leave the hive at one time.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY, MAY 4—

Dresden International Hort. Exh. (May 4-12).
Soc. Franç. d'Hort. de Londres meet.
German Gardeners' Soc. meet.

TUESDAY, MAY 7—

Mannheim International Exh. of Orchids (3 days).
Scottish Hort. Assoc. meet.
Nat. Amateur Gard. Soc. meet.

WEDNESDAY, MAY 8—

Roy. Caledonian Hort. Soc. Sh., Edinburgh (2 days).

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich—51°0'.

ACTUAL TEMPERATURES:—

LONDON.—Wednesday, May 1 (6 P.M.): Max. 52°; Min. 41°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—Thursday, May 2 (10 A.M.): Bar. 29.8; Temp. 55°; Weather—Bright.

PROVINCES.—Wednesday, May 1 (6 P.M.): Max. 51° Ireland S.; Min. 45°, Blackpool.

SALES FOR THE ENSUING WEEK.

TUESDAY—

The beneficial interest in the lease of Kew Nursery, Stanmore Road, Richmond, Surrey, comprising Greenhouses, Piping, Boilers, Buildings, &c., on the premises, by Protheroe & Morris, at 12.

TUESDAY AND WEDNESDAY—

Duplicate Plants from the "West Bank House" collection of Orchids, at West Bank House, Heaton, Mersey, by Protheroe & Morris, at 1.

The whole of the stock of Palms and Plants, Utensils, &c., at Kew Nursery, Stanmore Road, Richmond, Surrey, by Protheroe & Morris, at 12.

WEDNESDAY—

Herbaceous and Border Plants, and Bulbs, Palms, &c., at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.

FRIDAY—

Orchids in variety at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.45.

Comparatively few botanists and horticulturists of the present day know anything more of Dillenius than that there was such a person. Nevertheless, in spite of the rapid progress of botany along somewhat different lines, the memory of Dillenius is worthy of honour. Botanists have, therefore, cause to thank Mr. Claridge Druce, the curator of the herbaria in the University of Oxford, for a book* recently published by him, and to which the present Professor of Botany has affixed an introduction.

Dillenius was the contemporary of Ray and of Linnæus, and although he did not rise to their level, his merits amply entitle him to be mentioned in association with them. From a botanical point of view, his work among the cryptogams, especially the mosses, was the most important, but to horticulturists he is best known by his *Hortus Elthamensis*, the figures of which are still valuable. This was an account of the plants growing in the garden of James Sherard, the brother of his friend and patron, William Sherard. The last named left his books and the sum of £3,000 to the University to found the Sherardian Professorship of Botany, at

the same time indicating Dillenius as first Sherardian Professor. The *Hortus Elthamensis* consists of two folio volumes, published in 1732, with over 300 plates, many of them devoted to the illustration of Mesembryanthemum and other succulent plants. The book before us contains, as has been mentioned, an introduction from Professor Vines, in which the historic value of his predecessor's researches among the mosses and other cryptogams is clearly set forth. Then follows a biography of Dillenius, a list of his published works, a selection from his correspondence, and an account of the plants in the herbarium. This account must have demanded an immense amount of labour and watchfulness in its compilation, and great judgment in determining the nomenclature and its relation to that now in use. Incidentally, we may mention that Dillenius was the first to propose the genus *Narcissus*. The species he mentions are *N. pseudo-narcissus* and *N. biflorus*, both indicated by the binomial system in vogue before Linnæus adopted and rendered popular the binomial system of naming plants, than which he rendered no more signal service to botany. A copious index completes the work. We can but congratulate Mr. Druce on the completion of this formidable task, and if it is not too much to expect, we hope he may find leisure to give us similar synopses of the works of Sherard and Sibthorp.

OUR SUPPLEMENTARY ILLUSTRATION to the present issue is reproduced from a photograph of part of the interior of the Number 4 plant-house at Kew, commonly termed the greenhouse. It is a large + shaped house having a span roof, and is devoted all the year round to the exhibition of temperate plants in flower. There are a few beds extending along the centre of the house, in which Camellias and many other foliage plants are planted out. Amongst these are placed from time to time specimens cultivated in pots, and smaller plants are arranged on the shelves at the sides of the structure. Numerous species of climbing and trailing plants are trained under the rafters and allowed to droop over the pathways. Our photograph was taken when the Indian Rhododendrons, Japanese Pæonies, Eupatoriums, and other spring-flowering plants were in full bloom. Fuller notes of the plants now blooming in this house appear on page 280.

THE NATIONAL CHRYSANTHEMUM SOCIETY.

—The schedule of prizes and list of members for 1907, as well as the annual report for 1906 of this society, have lately been issued. It is proposed to hold three exhibitions and a market-show this year, as in previous seasons. The society is considered to be in a satisfactory condition financially, and an increase in the number of fellows and members is desired to still further increase its working powers.

FLOWER SHOWS AT BIRMINGHAM.—Two summer flower shows were held at the Botanical Gardens, Edgbaston, last year under the auspices of the Birmingham Botanical and Horticultural Society, and at a recent meeting, presided over by the chairman, Mr. NEVILLE CHAMBERLAIN, it was decided to hold two similar shows this season, one on June 12 and another on July 3. The committee is very grateful to those exhibitors who supported the shows last year, and will be glad to welcome them and others on the dates mentioned. The hon. secretaries are Mr. T. HUMPHREYS and Mr. W. H. WHITELOCK.

THE CORRUPTION BILL.—Mr. J. M. HENDERSON, at a recent meeting of the House of Commons, asked the President of the Board of Trade whether he was aware that, consequent upon the provisions of the Prevention of Corruption Act, 1906, and the action of various trade-associations in making public the provisions thereof, offers of secret commission to agents were now being extensively circulated in this country from firms writing from abroad, the offer in some cases amounting to a very large percentage on the amount of the order sent to the foreign firms in question, whether he would give the matter his attention at the earliest possible opportunity. In reply Mr. LLOYD GEORGE said: My attention has already been called to this matter, and a notice was published in the *Board of Trade Journal* for February 21 last, in which it was pointed out that the acceptance of any such offers from foreign firms renders agents in this country liable to penalties under the Act. I trust that the efforts which I understand are being made by various associations of British traders to put an end to the practice will be successful.

SURVEYOR'S INSTITUTE.—The next meeting will be held on Monday, May 13, when a paper on "The Prevention of Corruption Act, 1906," will be read by Mr. MAURICE L. GWYER, barrister-at-law. The council have accepted an invitation from the Scottish Committee of the Institution to hold the next country meeting at Glasgow on May 23 and 24. Visits have been organised to various works and places of interest in Glasgow, and the Clyde trustees have allowed the use of a steamer for viewing the harbour and shipping yards. Various excursions have also been arranged. An afternoon reception will be held in the gardens of the Royal Botanic Society, Regent's Park, on Tuesday, June 18, from 4 to 7 p.m. Particulars will be issued shortly.

METEOROLOGICAL NOTES FROM GLASGOW.—

Mr. JAMES WHITTON publishes, as in former seasons, his meteorological notes and remarks upon the weather during 1906, with its general effects upon vegetation. These notes are compiled from the records kept at Queen's Park, Glasgow. Briefly summing up, it may be stated that the promise given by a previous year of favourable weather was but partially fulfilled, sudden atmospheric changes causing much disappointment. A cold spring with a disastrous hailstorm in May checked early growth, and it was not until June that much recovery was noted. Hay crops and cereals and root-crops were, on the whole, up to average, while most trees and shrubs did well, save those damaged after growth was started. Although the present season seems not so promising as last year appeared at first to be, there is yet sufficient display of buds to ensure good results unless again unexpectedly checked.

BERLIN.—A great international horticultural exhibition will be held in Berlin in April, 1909, under the auspices of the Verein zur Beförderung des Gartenbaues in den preussischen Staaten. All enquiries should be addressed to the General Secretary of the Society, Invaliden Strasse 62, Berlin.

THE NEW ZEALAND INTERNATIONAL EXHIBITION, 1907.—Messrs. SUTTON & SONS, Reading, have been informed by cable that they have been awarded by the jurors four gold medals for their exhibits of samples of their pedigree stocks of farm seeds, vegetable seeds, flower seeds, Potatoes; models of various types of Mangels, Swedes, Turnips and vegetables; specimen bunches of Grasses for temporary and permanent pastures; horticultural requisites, cutlery, &c.

* The Dillenian herbaria, an account of the Dillenian collection in the Herbarium of the University of Oxford, together with a biographical sketch of Dillenius, selections from his correspondence, notes, &c. By Claridge Druce, M.A., edited, with an introduction, by S. H. Vines, M.A., F.R.S., Sherardian Professor in the University, Oxford, at the Clarendon Press.

THE SEEDLESS APPLE.—The following is an extract from a "warning" by L. R. TAFT, of the Michigan Agricultural College, addressed to the farmers of that State, but of interest to all nurserymen, and reprinted in the *Weekly Florists' Review*: "From various sources it has come to me that agents of a certain company have been taking orders for the seedless Apple, and that many farmers and fruit-growers have agreed to take one or more trees at 2 dollars each. They have been led to do this by the representation that the fruit, in addition to being large in size, handsome in colour, fine of texture, and of delicious flavour is seedless, seedless, and free from the attack of the meddling moth and frosts. I have been watching this variety for the last three years, and am convinced that it is in every way inferior to our common varieties which can be obtained for 10 or 15 cents each. The State law requires that every person selling nursery stock in Michigan shall take it a license. Sellers who omit this precaution are liable to incur the penalties of the law."

GARDENING AT THE ZOO.—It is pleasant to note, in the recently-issued annual report of the Council of the Zoological Society, a well-deserved tribute to the energies of Mr. J. J. OUNG, garden-superintendent, who has almost completed his 27th year of office. During the last year the opening of the new section of the gardens—part of which accommodated the Prince of Wales's collection of Indian animals entailed much work which had to be accomplished in a short time, yet this was successfully effected. The new part of the gardens promises to be the most picturesque part of all, and there already a goodly show of spring flowers both in this and in the older portion of the grounds.

HOW TO STUDY WILD FLOWERS. By the Rev. GEORGE HENSLAW, M.A., &c.—This is the first impression of this hand-book, thus proving at it has already made its way into popularity. The information is clearly, and, of course, accurately given, and there are many illustrations, some of them coloured. While useful to those who have no other guide this book will also be of serviceable to tutors for reference, and to assist them, as the writer says, in "training the young mind in systematic observation and accurate habits." The appendix describes the coloured plates, and there is an index of the genera of the plants mentioned. *How to Study Wild Flowers* is published by the Religious Tract Society, 4, Bourne Street.

THE BOOK OF THE OPEN AIR.—The second part of this handsome book is to hand, and would please every lover of the country. The contents include a diary for May; a paper on "Making of Scenery," by EDWARD CLODD; "Life-story of a Badger," J. C. TREGARTHEN; "Some May Flowers," by Canon VAUGHAN; "The Bee Mind," GEORGE A. DEWAR; "Story of some Pebble Hills," by W. JOHNSON, &c. As these are accompanied by several coloured plates from drawings and photos., it will be seen that various phases of open-air life are considered. The letterpress is light and readable, and encourages the observation, not the destruction, of our country-side creatures.

NATURE'S OWN GARDENS. Written and illustrated in colour and line by MAUD U. CLARKE. London: J. M. DENT & Co.; New York: E. P. DUTTON & Co.—Nature's own gardens are, of course, those not merely beautiful, but effective masses of flowering plants that best lend themselves to description and illustration. We are told here of some of the flowers that pass in long procession through the year, especially through the warmer seven months of it, and attention is rightly enough called to the inconspicuous beauties as well

as to the more showy glories. For coloured illustrations the writer has chosen the bolder treasures; a golden page represents marsh Marigolds and bitter Cress, a brown and blue effect is called Forget-me-Not. Frankly, the many large plates are illustrations of general effects rather than careful or minute studies of nature's gardens. The black and white sketches found here and there throughout the pages are more satisfactory, for accuracy of form has not been sacrificed to colour effects. The letterpress has no pretensions to being instructive. The writer loves her flowers, and would fain have others share the admiration that ever rises new within herself at the sight of country-side pictures. This is comprehensible, and we hope readers will not be satisfied without also observing for themselves now that yet another book is pointing them in the right direction. We also agree that many more of nature's plants might be admitted into our own artificial gardens, but it is well to know which to exclude owing to their probable rampancy, and also how to group the others. To mix Cow Parsnip and other hedge-row friends with rose-coloured Phloxes would satisfy a love for contrast rather than that of harmony or appropriateness, while double red Daisies may not look their best by the water-side among their wild relations. It is somewhat of an infringement in *Nature's Own Gardens*, which we have just been told are so perfect. The Anemone wood in April, the Bluebell carpet in May, the Cornfield, the Primrose banks, the summer river—these are all of nature's planting (as regards the wild-flowers within, of course)—but "when each and all of the nature gardens are so lovely in their own particular way it is unwise to show partiality, and yet there is something dangerously like it, if I say that the garden of the Grass-fields in June seems to hold the largest possibilities of any. Towards the end of the month there is such a flower show that is hardly repeated during the year in any other situation." Many will quite endorse the writer's opinion.

BRITISH PLANTS.—From the Department of Botany of the British Museum (Natural History), Cromwell Road, London, S.W., comes a *List of British Seed-Plants and Ferns*. Those who are familiar with the old London catalogue will be glad to possess a new list framed in accordance with the latest official pronouncement at Vienna. It is of no use offering any criticism upon a *res judicata*, but, at any rate, we may point out that one of the main rules laid down to be followed is that which prescribes that the earliest specific name is henceforth to be adopted, no matter under what genus that name was first used. In this country we have been in the habit of accepting the specific name given by that author who first placed the species in the correct genus. Finality in this matter is, we fear, unattainable, and uniformity of practice hardly less so, but this "list," prepared by Dr. RENDLE and Mr. BRITTEN, will, at any rate, contribute towards these most desirable objects. The arrangement of the orders is that of *Bentham's Handbook*, whilst for the limitation of genera and species Messrs. GROVES' edition of *Babington's Manual* as the most recent descriptive British flora has been followed. Cross references are made to the latest editions of (i) *Bentham's Handbook*; (ii) *Hooker's Students' Flora*; and (iii) *Babington's Manual* in those cases where the name adopted in the present list does not correspond with that in one or other of the books just mentioned. This must have been a troublesome piece of work, and one beset with pitfalls, for, without critical comparison of type specimens—not always practicable—it is, we suppose, quite impossible to avoid error, and to assert positively that any given name is actually synonymous with that proposed by some former authority. To illustrate the plan fol-

lowed by the compilers, we may say that *Clematis Vitalba*, which heads the list, is adopted by all the authorities, and, therefore, no cross reference is required, but *Thalictrum majus*, of Crantz, has the figures I. and II. placed after it to show that the same plant is included under *Thalictrum minus* in (i) *Bentham*, and (ii) *Hooker*. In the old London catalogues the species were all numbered consecutively, which greatly facilitated the arrangement of the specimens in the herbarium. In the present list only the genera are numbered, but as a rule not the species. Within the limits of some of the genera, however, the species are sometimes numbered, as in *Sedum*, the species of which are numbered from one to eleven. In *Oenanthe* no numbers are affixed to the species, and so with many others. We have not discovered the reason for this diversity of practice. After all, general usage and convenience will prevail over the rules of strict priority, at least for some generations to come. We can hardly imagine, for instance, the common white Water Lily being generally called *Castalia alba*, a name proposed by GREENE as lately as 1888, or that the common yellow Water Lily will henceforth be generally known as *Nymphaea lutea*, or that the Winter Aconite will henceforth be known as *Cammarum hyemale* of GREENE. These changes may be quite justifiable from some points of view: we are not attempting to dispute their legitimacy, but they are certainly inexpedient, and their most appropriate place would be among the list of synonyms, with an indication of the date. A list of the kind prepared by Dr. RENDLE and Mr. BRITTEN is most serviceable, and will, we hope, save much time and research to future students, who will be able to devote themselves more completely to the study of the plants themselves, and less to the unravelling of the opinions and practices of those who wrote about them in past times. In saying this, we by no means wish to derogate from the importance of historical research, which, arid though it looks, is often fascinating, but to emphasise the fact that for the average student it is of more importance to study the plant itself, and of less value to disinter the ancient literature relating to it.

THE ELKS HORN FERN (PLATYOGONIUM ALCOICORNE).—All Fern cultivators are familiar with this species, with its broad, sterile fronds placed in a different plane from that of the much-lobed fertile fronds, which bear their spores on the lower surface. M. POISSON, in the *Bulletin of the Botanical Society of France*, describes and figures a case in which the ordinarily sterile frond bears spores upon its upper surface and is directed upward.

PLANTS OF THE HOLY LAND.—A new work entitled *The Flowers and Trees of Palestine*, by Miss AUGUSTA A. TEMPLE, is announced for early publication by Mr. ELLIOT STOCK. It will contain a description of the flora of the country, with some 40 photographic illustrations of the chief examples mentioned and a full glossary of plant names.

SLUGS.—M. H. DU BUYSSON, as cited in the *Moniteur du Jardinier*, speaks very highly of the use of sulphate of iron, green vitriol. The crystals are scattered freely on the soil. The result is that the slugs are annihilated and the plants uninjured.

SEEDLESS COCOA NUT.—Whatever may be said in favour of seedless Apples we imagine that seedless Cocoa Nuts would not appeal to anyone but the pure botanist. He at least would be interested in the figures and description given of these productions in the *Agricultural News*, published in Barbados.

NATIONAL FRUIT-GROWERS' FEDERATION.—The annual general meeting will be held at the Royal Horticultural Hall, Vincent Square, Westminster, on Monday, May 6, 1907, at 8 p.m. In addition to the routine business to be discharged, Mr. E. S. SALMON will read a paper on "The American Gooseberry-mildew in England: the Present State of Affairs." Lantern slide illustrations of the appearance of diseased Gooseberry shoots and fruit will be given. A discussion will take place on the bearing of the above question on the proposal to form a sub-department of the Board of Agriculture. The subject of "Damage by Wild Birds" will be introduced by Mr. F. SMITH.

ALEXANDRIA.—The Horticultural Society of this town is in a flourishing state, owing to the zeal of Judge SANDARS, the president, and the interest taken in the matter by the English Colony and many of the Egyptian residents, including M. MONFRONT, the superintendent of the municipal parks and gardens. The treasurer is Mr. P. W. CARVER, the head of one of the large cotton mercantile houses. Perhaps the most remarkable feature of the show, which opened on the 20th ult., was the series of beds of Tom Thumb, Phlox Drummond, exhibited by M. MONFRONT.

MR. McDONALD.—We are informed that Mr. DONALD McDONALD has retired from the position he has held for over 30 years with Messrs. JAMES CARTER & Co. He leaves with the good wishes of all at Holborn and was the recipient of some handsome presents. He will still reside at Bexley Heath, Kent.

AURICULA MISS BERKELEY.

THIS variety of Alpine Auricula is an advance on any previous variety of the white-centred type. It is rather curious that all the white-centred varieties have purple, maroon purple, lilac, or bluish tints, while the yellow centred varieties are all of crimson, reddish crimson, and red of various shades. They all have shaded edges, whether they are gold-coloured or white, and there ought to be no powder on the flowers, such as is always present on what the fanciers term the "show" Auriculas. The variety Miss Berkeley is one of a large number of seedlings raised by Mr. J. Douglas by crossing a variety named Teviotdale with a more recent seedling. It gives a bold truss of flowers on quite an erect, stout stem, which requires no support. The corolla (pip) has a white circular centre; the margin is of maroon-purple at the centre, shading off to a paler tint at the margin.

These Alpine Auriculas are vigorous growers, and well adapted for planting on the north side of a rock garden, or the front row of a herbaceous border. The plants may either be set out singly or in groups of three, or as many as a dozen may be put in a group. The flowers are not so large in size as those grown in flower pots in greenhouses or frames, but the colours are richer and deeper. The Auricula does not need a very rich soil, nor any special mixture. All that is required is a good loam, with a fourth part decayed manure, and some leaf-mould, with a little sand to keep the compost open, if it is not already of a sandy nature.

VEGETABLES.

CUSTARD AND BUSH VEGETABLE MARROWS.

THE Custard Marrow is a delicious vegetable in season from June to November, and with the Custard I have bracketed the Bush, for though quite distinct in flavour, they are somewhat similar in growth. They should both be cooked and eaten when in a young state and before the seeds mature. Many persons grow the ordinary Marrow merely for its size, and when cooked it is cut up, and, of course, for market

supplies it is very useful, because it is capable of standing much rough usage. For home supplies, however, the smaller Marrows are far preferable to the ordinary vegetable Marrow and quite superior in flavour. Most of the Custard and Bush Marrows are compact growers, but

medium for these plants, and I have often seen them planted on large masses of manure. Grown thus, in a wet season they make too much leafage, the fruits frequently turn yellow and drop before they are of any considerable size, and the crop is poor. My best results from

FIG. 119.—ALPINE AURICULA MISS BERKELEY: COLOUR OF FLOWERS MAROON-PURPLE AND WHITE.

one of the best, Sutton's Improved Custard, has a trailing habit, and this is a great cropper. I have grown several distinct types from seeds obtained from the Continent, and they were remarkable for their free growth and large leaves. Many persons provide too rich a rooting

both the Bush and the Custard varieties were obtained by planting in the open and giving each plant a little decayed manure and leaving a good space for watering. The Bush forms can be grown somewhat closely together, and in hot weather they greatly benefit by sprinklings of

water given late in the day. This keeps down red spider, one of the most troublesome pests of these plants. For an early crop in frames, these small Marrows are most suitable. Much heat is not required, and the plants resent too close a treatment, which causes failure in the setting of the blossoms. Given ample ventilation, good fruits may be cut in a few weeks from the time the seeds are sown. To obtain a succession, three sowings should be made, making the last sowing late in June. The plants will require some protection at night-time in the late autumn. Plants raised from seeds sown in May or June, and planted out, will give a full summer crop, and will, providing some food, such as liquid manure, be given them, furnish fruits till the vines are cut down by frost in the autumn.

Both the Bush and the Custard Marrows should be cut before the seeds harden; indeed, many persons cut them before the seeds are formed. They are best cooked whole. Bush Marrows are green, white, or yellow, and the fruits are often produced close to the centres of the plants. They are also known as Cluster Marrows. Cut in halves, filled with finely-chopped, highly-seasoned meat, and cooked they make a capital dish. For gardens limited in size, the Bush varieties are most suitable on account of their compact growth and free-bearing qualities. *G. Wythes.*

DAFFODILS AT DITTON.

BEING reminded by Messrs. Barr & Sons that the Daffodils at Ditton were in their full beauty, we accepted their invitation to view them, for although we have for several seasons past journeyed to Ditton at Daffodil season, it has always been an outing of pleasure, and that notwithstanding the somewhat severe climatic conditions we have generally experienced. The wind has always seemed to whistle over the neighbouring railway bank, as though its one object was to shake the countless spear-like leaves and to set the heads a-nodding. The Daffodil has not only to "take the winds of March with beauty," but also the showers of April as well: still the Narcissus in its season of flowering is more independent of fair weather than most flowers; its bulb contains a store of food ready for assimilation, and its pollen is admirably protected from the rain by its coronet. The differences of this latter organ in the various flowers are remarkable, and to it the flower owes much of its charm, but what it exactly represents is a matter of question. As the prevailing colour is yellow, the statement that it represents an additional series of barren stamens may perhaps be the true one; at any rate, there can be no question but that its principal function is protection of the pollen from rain. Even in the Poet's Daffodil the brightly-coloured "eye" acts as a little gutter to exclude the wet. In this section we find the beautiful bright red which has been worked by the hybridist into the yellow of the bigger crowned flowers, and the loveliest shades of orange, apricot, and deep lemon are found in such varieties as Peach, Lucifer, Gloria Mundi, and Firebrand, some set in a white and others in a creamy-white perianth. The purest white of all is found in the starry segments of the true, Narcissus—*N. poeticus*, which has received its share of attention in the matter of improvement; and one of the very finest is Cassandra, tall and robust of habit, and with large, spreading segments encircling a broad rim of fiery red—a great advance from the old Pheasant's Eye. Later raised novelties in the same section are Dante, Horace, and The Bride, all great improvements of the type. In contrast to the tiny rim of the Poet's Narcissus is the relatively huge trumpet of the large crowned or Magni-coronati section, some, as in the variety King Alfred, all yellow, others, such as the peerless Weardale Perfection, being white and yellow; and

in the magnificent Peter Barr and the newer Mrs. George H. Barr, having almost all the yellow eliminated from both the perianth and trumpet, so that the flower is an albino. The hybridist has evolved flowers intermediate in form in all stages from the tiny crown to the biggest trumpet, and has indeed broken down all barriers between the various sections.

One of the first varieties we noticed was the beautiful bi-colour Madame Plomp, a fine bold flower that holds itself well erect, and displays its golden trumpet to advantage. Duke of Bedford was almost over, for it is one of the earliest of the large trumpet varieties.

Near by was Peach, with its apricot-coloured crown set in a white perianth; and Catherine Spurrell, with citron-yellow cup. Sprightly is a sturdy flower with golden yellow trumpet, a cheap but good variety. Monarch still ranks as one of the best of the large yellow trumpet Daffodils, and in its size and form accompanied with substance has much merit. It was raised at Surbiton, as was also Lord Roberts, which may be described as a glorified Emperor. Mention must also be made of Duchess of Westminster, not new certainly, but one of the very choicest of the Leedsii type, a general favourite and one largely grown for market purposes. In the younger flowers the tube is tinged with orange, that contrasts well with the white petals. A very early flowering variety is Blackwell, of the incomparabilis type, with fluted cup, a flower that remains fresh for a long time when cut. We pass by the big Glory of Leiden, and notice the "Queen" of the white trumpet Daffodils, Madame de Graaff, a variety within the easy reach of all purchasers. All its attributes are good, and there are few Daffodils more beautiful. Another standard variety is J. B. M. Camm, a bi-colour flower, of exquisite and refined shape. It is admirable for pot culture, and is free-flowering either in pots or in beds. Commander is an old variety, but must not be neglected on that account, for it is still one of the best of the incomparabilis type. Ariadne is a beautiful flower with a beautiful name. It has gained numerous awards. Flowering early, it displays an open, soft lemon-coloured cup in a perianth of ivory whiteness. King Alfred we have already mentioned as a large trumpet flower, and it is to be recommended for stiff, damp soils, where it grows to an immense size. It may best be described as a glorified maximus. Then there were also noticed Cleopatra, Seraphim, Eileen Mitchell of the drooping triandrous section, with reflexed perianth of snowy whiteness; Maggie May, a white Sir Watkin; Egret, George Philip Haydon, a fine yellow trumpet Daffodil, new in 1905, sturdy in every respect, and shaded soft yellow; C. H. Curtis, also new, very pretty in the cup, which expands in a broad rim; Royal Star, with flattened eye tinged with red; Cloth of Gold, Shakespeare, Strongbow, Sabrina, and a host of others.

In a wind-screened portion of the nursery are the seedlings, and with what eagerness are they watched to see if some new flower of merit has opened! But novelty raising does not result in so many rewards as formerly, not that good things are lacking, but that it is difficult to surpass those already in existence. Thus in the seed beds we noticed many fine varieties, but being most of them like existing types they would probably be passed over. Still some show great promise, notably a big yellow trumpet Daffodil, of great strength in flower and foliage, and another with a short tube that is frilled to a remarkable degree. Then we also noticed one that seemed an improved Gloria Mundi, with a magnificent coloured tube. But as all the seedlings are unnamed, we must watch for their advent when presented for award before the recognised societies, when their merits will be duly considered and their points compared with flowers of standard form. Messrs. Barr's latest success is in Corallina, a description of which appears in our last issue (p. 273).

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

FRUIT GROWERS AND BAD DEBTS.—A meeting, largely attended by market gardeners of the district, was held at Pershore recently to see what was possible in the way of co-operation and to discuss the desirability of forming an association to protect their interests. The chairman of the Pershore Traders' Association presided, and some interesting addresses were delivered. Mr. S. Hosgood, a leading solicitor in the town, in the course of an interesting speech, said that no pest caused greater damage to the grower than the commission agent pest, who obtained large quantities of goods and never paid for them. He instanced a case where a grower who had spent £65 on labour on the crop sent a consignment amounting to about £80 to an agent in Scotland, who never paid for them. The agent had given the usual banker's reference on his note heading, and on this reference growers seemed to place an enormous amount of confidence—a confidence altogether undeserved. It was, however, perfectly easy for growers to protect themselves. He advocated the drawing up of a white list and a black list, but they must have a committee of growers in the district. There were any number of commission agents who were above suspicion, and they would be glad to see the unscrupulous turned out of the fold. Mr. H. H. Phelps, ex-president of the Birmingham Fruit and Potato Association, speaking as a salesman, said all honest dealers deprecated the presence of the dishonest in their midst. He urged, however, that growers must be fair to salesmen. He favoured the preparation of a black list. Mr. G. F. Hooper spoke against the practice of local salesmen sending out price lists early in the season. If the prices therein were low they remained all the season. Mr. W. J. Gardner remarked that an association of gardeners could do excellent work in many ways, and particularly in the matter of railway rates. Further interesting discussion followed. Eventually it was decided to form a gardeners' association as part of the traders' association. If it reaches large proportions a separate society will be established. There should be no difficulty in this matter, but the gardeners of the Vale are notoriously bad at combination. It may be that there is still a large amount of trade jealousy, but I think this is gradually dying out now that a different class of gardeners are coming into the district. There has been a market gardeners' association at Evesham for some years, but so far as I know it has never seriously taken up matters of this kind. Perhaps the example of Pershore may spur them up. *H., April 27, 1907.*

"GOOD KING HENRY."—This plant is *Chenopodium Bonus-Henricus*, and is widely known as Mercury or Lincolnshire Spinach. It is an excellent vegetable from April till June. Its value has been recently brought to my notice by a medical gentleman, who thinks most highly of it in cases where Spinach or similar vegetables are required. Many years ago I grew this plant in Lincolnshire, and it is grown in most gardens in that and the adjoining counties. The plant is a perennial, a native of Britain, and found in many parts of Europe. At this season the young shoots are cut and tied in bundles for cooking. Later, when the shoots age, the leaves are gathered like Spinach and cooked in the same way. The plant is easily grown from seeds sown in the spring in good, deeply dug soil. The plants should be kept well thinned. In cottage gardens it is mostly grown by dividing the plants early in the spring, and these soon give new growths for cutting the same season. *G. W.*

FRITILLARIA IMPERIALIS.—Amongst the many early flowers that adorn the garden at this time of year, the above species is a very grand object, and it seems to be exceptionally floriferous this year. Mine are very fine just now, having between 300 and 400 heads of bloom, and some of them are 4 feet high, mostly red varieties; the yellow ones appear more delicate, for they seem to diminish. I have two or three other colours. Maxima is altogether larger in flower and stature, and another with buff-coloured flowers is attractive. The variegated plants do not flower so freely. *W. C. B. by Google*

BIRDS AND BUDS.—Bullfinches have again been busy with the fruit buds in these gardens since early in the year. They particularly attacked two standard trees of Plum and Damson, and would have done much damage had they not been prevented; but the trees have since been laden with blossom. They also attacked slightly the wall trees. During a few days when things were quiet in the walled gardens a bird was noticed, but not until a number of fat Pear buds had been destroyed. After spraying with the Woburn wash the buds were not attacked. Bush fruits have been scarcely touched, although not protected in any way. *G. H. Head, Kingsdon, Taunton.*

PRUNING OR NON-PRUNING FRUIT TREES.—Although I agree with "Moderate Pruner" that demonstrations of the value of pruning of fruit trees may be needless now, yet in advising the planting of certain sets of Apple trees at Wisley for purposes of pruning or non-pruning demonstration, I had in mind the fact that the Wisley Gardens are intended specially as a school of horticulture, and as such it is of the first importance that the students there should be provided with means of fully testing the merits or demerits of pruning, as is ordinarily practised. Mr. Udale has shown how natural it is that non-pruned trees should in time become larger than are pruned trees. He also shows that it is the annually pruned trees which, after all, do produce the greatest quantity of wood over a series of years, because the annual stimulus to produce new wood excites root action, a stimulus that in time becomes deficient with non-pruned trees; hence, although wood shoots are dense, both leafage and fruits are smaller than is the case with those products on properly pruned trees. It is well known that whilst a non-pruned tree may produce in double or treble numbers about the same weight of fruit as a pruned tree, yet that from the latter has the advantage of being of much greater market-value because of greater size and finish, and in addition has not in any appreciable degree created so great a strain on the tree's reproductive powers, relatively because the production of pulp is not so exhaustive as seeds, cores, or stones, which require the highest efforts of the plant. *A. D.*

BUTTER (WAX) BEANS.—A contribution, signed *F. M.*, on this subject, appeared in your issue of July 7 last. I am not aware of any progress made in this country in connection with Butter Beans, although, as a vegetable, they take a very favourable position abroad. I have had a long personal experience in this country with this delicious vegetable, delicious if rightly prepared, and not merely on the popular "plain boiled" method. The Bean, if carefully dressed, is relatively on a level in its season with the popular Seakale in the early months of the year. As the planting season is now on, and will continue until the end of May, plantings may be made for succession. In the more important German catalogues, there appear fully a dozen varieties of Butter Beans, both dwarf and runner sorts. The finest variety, as found by many years' experience at my hands, is the "Flageolet," among that series, and it exists in both dwarf and runner sorts. When the crop is ready for gathering during August and September, it has a very attractive appearance on the bine. The preparation for table consists in cutting off the tops and tails, and carefully removing any side strings. Then tie the Beans whole into small bundles like Asparagus, place them for about 20 minutes in boiling water, with a little salt added, until quite tender; strain them thoroughly, and place them lengthwise in a vegetable dish, with *pale* raspings. Pour over "oiled" (not the more popular melted) butter and thus serve. *H. H. R.*

TRADE NOTICE.

FAILURE OF NURSERYMAN.

The first meeting of the creditors interested under the failure of George Edward Poole, 9, Oakfield Place, Clifton, and of Warwick Nurseries, Warwick Road, Redlands, Bristol, Nurseryman, was held on the 26th ult. The summary of accounts showed liabilities amounting to £242 and assets estimated to produce £206 after deducting preferential claims, thus leaving a deficiency of £36. According to the observations of the official receiver, debtor, who is 27 years of age, began business in 1904 with a capital of £250, of which £225 was paid for the business. He attributed his insolvency to want of capital, and stated that he spent too much upon the erection of greenhouses without having control of sufficient money to pay for them or to carry on the business.

SOCIETIES.

ROYAL HORTICULTURAL.

APRIL 30.—The Royal Horticultural Hall was again well filled with exhibits at the meeting on Tuesday last. In addition to the Orchids, Daffodils, and other exhibits before the committees of the Royal Horticultural Society, there was the annual display of Auriculas and other Primulas shown under the auspices of the NATIONAL AURICULA & PRIMULA SOCIETY (Southern Section), a report of which will be found in another column.

The ORCHID COMMITTEE recommended awards which included one Botanical Certificate, three First-Class Certificates, and four Awards of Merit.

The FLORAL COMMITTEE's awards consisted of one Award of Merit to a new winter-flowering Carnation, and a similar award to a variety of *Cydonia japonica*.

The FRUIT AND VEGETABLE COMMITTEE did not recommend an award to any novelty.

The NARCISSUS COMMITTEE recommended two Awards of Merit to new Daffodils, and a similar award to a new Tulip.

The best and most novel exhibit in the show was one of *Gloriosa rothschildiana*, shown in a growing condition by the Hon. WALTER ROTHSCHILD, which was appropriately awarded a Silver-Gilt Lindley Medal, the Lindley Medal being one specially reserved for the encouragement of good cultivation.

In the afternoon a lecture on "Amateurs, and Horticultural Law" was delivered by Mr. H. MORGAN VEITCH.

Floral Committee.

Present: W. Marshall, Esq. (Chairman); and Messrs. C. T. Drury, Geo. Nicholson, Jno. Green, T. W. Turner, W. Thompson, M. J. James, C. E. Shea, C. E. Pearson, R. C. Notcutt, H. J. Cutbush, W. Howe, R. Hooper Pearson, C. Dixon, E. T. Cook, E. H. Jenkins, and P. W. Barr.

A magnificent group of *Souvenir de la Malmaison* Carnations was contributed by C. F. RAPHAEL, Esq., Porter's Place, Shenley, Herts. (gr. Mr. A. Grubb). The plants were all of a pink-flowered variety, and some of them bore as many as ten good flowers. The exhibit represented first-class cultivation. (Silver-Gilt Flora Medal.)

The Hon. WALTER ROTHSCHILD, Tring Park, Tring (gr. Mr. A. Dye), made a charming exhibit with the beautiful *Gloriosa rothschildiana*, which formed a whole-page illustration in our issue for May 23, 1903, p. 323. The method of displaying the flowers was novel and natural, the plants being trained on arches of trellis work and planted in boxes, from which the arches sprang. The culture of the plants was all that could be desired, for they were crowded with the beautiful Lily-like crimson flowers, and exhibited luxuriant growths; a carpeting of moss on the boxes and an edging of the white *Astilbe* furnished a pleasing finish to the display. (Silver-Gilt Lindley Medal.)

Messrs. ROBERT VEITCH & SON, Exeter, exhibited sprays of interesting plants in flower. The yellow-flowered *Sophora tetraptera*, with Acacia-like foliage; *Myosotidium nobile* and its white form; *Sutherlandia frutescens*, a red leguminous flower with pinnate foliage; *Rhododendron Luscombe's* Seedling, and magnificent sprays of *Erica Veitchii* X.

Messrs. JAMES VEITCH & SONS, LTD., King's Road, Chelsea, made an imposing exhibit of forced shrubs and ornamental flowering trees. Tall plants at the back of *Pyrus Malus floribunda* and *Cerasus pseudo-cerasus* J. H. Veitch overhung smaller plants of *Wistarias*, *Hydrangeas*, *Peaches*, *Cherries*, and *Rhododendrons*, finishing in the foreground with the floriferous *Schizanthus Wisetonensis*, and the pretty-leaved *Eurya*. A separate group comprised choice indoor-flowering plants, *Cinerarias*, *Kalanchoe Felthamensis*, tiny plants of *Exacum macranthum*, a choice example of *Medinilla magnifica* and other equally beautiful subjects. (Silver-Gilt Flora Medal.)

J. C. TREMAYNE, Esq., Heligan, Mevagissey (gr. Mr. S. Jordan), showed *Rhododendrons*, *Camellias* and *Roses* from the open. The *Roses* were remarkably fine, and included the varieties *Catherine Mermet* and *Niphetos*.

Messrs. PAUL & SON, The Old Nurseries, Cheshunt, showed sprays of interesting and uncommon plants. *Caragana jubata* is a curious leguminous flower, produced on the old spiny branches; *Arbutus procera* has its inflorescence in a dense terminal spike; *Larix koraiensis* is supposed to be new to gardens; *Illicium religiosum* has white strap-shaped petals. There were also some fine *Rhododendrons* such as *Lady Alice Fitzwilliam* and *Helen Schniffler*; *Excordas*, a pretty hybrid Musk Rose named *Snowstorm*, and several other plants of interest. (Silver Banksian Medal.)

Lord ALDENHAM, Elstree House, Elstree (gr. Mr. E. Beckett), displayed sprays of flowering and pretty-barked trees and shrubs from the collection at Elstree. (Silver Flora Medal.)

Mr. J. R. RUSSELL, Richmond Nurseries, Surrey, contributed a group of forced shrubs, in which the standard Lilacs, *Wistarias*, and dwarf plants of *Rhododendron molle* were pretty features. (Silver Flora Medal.)

Messrs. J. CHEAL & SONS, Lowfield Nurseries, Crawley, exhibited sprays of flowering shrubs, and of ornamental leaved shrubs, as well as species of *Pyrus*, &c., in pots. Messrs. CHEAL exhibited a weeping variety of the Japanese Cherry, under the name of *Prunus pseudocerasus pendula* Chealii! (Silver Banksian Medal.)

Messrs. JOHN PEED & SON, West Norwood, London, S.E., staged a group of ornamental-leaved *Acers* (Maples), interspersed with a few plants of showy *Clematis*, and edged with a border of *Eurya latifolia*. Some large *Panicles* were also displayed in the exhibit. (Silver Banksian Medal.)

Messrs. THOS. CRIPPS & SON, Tunbridge Wells, Kent, filled one corner of the Hall with a bank of fancy-leaved Maples of the palmatum and japonicum sections, and ornamental Vines, with a few other subjects, such as *Panicum plicatum*, *Euonymus latifolius*, and *Eurya intermingled*. (Silver Banksian Medal.)

Messrs. H. B. MAY & SONS, Upper Edmonton, London, displayed a good strain of herbaceous *Calceolarias*, choice crested and plumose varieties of hardy Ferns, *Vitis heterophylla*, the pink *Verbena* Miss Willmott, and a number of bunches of Zonal Pelargoniums. (Silver Banksian Medal.)

Messrs. HUGH LOW & CO., Bush Hill Park, Enfield, staged well-flowered plants of *Metrosideros* (the Bottle-brush tree), *Gerbera Jamesoni*, *Schizanthus Wisetonensis*, a very large-flowered *Abutilon* named *Triumph*, *Erica Cavendishii*, and the trailing *Lotus peliorhynchus*.

Messrs. J. CARTER & CO., High Holborn, London, exhibited a semi-circular group of *Cinerarias*, arranged on the ground floor. Plants of the stellate type were placed at the back, and others formed two small groups near the front, the rest of the exhibit being composed of approved varieties of the florists' or large-flowering strain. (Silver Banksian Medal.)

Messrs. HOBBS, LTD., Dereham, Norfolk, exhibited *Roses* both as plants in pots and as cut flowers. The rambling varieties in pots were capital, and included the new *Hiawatha*, a single crimson flower with white centre; the better-known *Lady Gay*, &c. A new Rambler, apparently from Germany, is named *Tausendschön*. It is distinct from the usual type, the flowers being very large, semi-double or double, and of a most pleasing shade of soft rose. (Silver Banksian Medal.)

Messrs. W. PAUL & SONS, Waltham Cross Nurseries, Herts, had a very attractive exhibit of *Roses* in pots, among which we noticed a distinct *Polyantha* variety named *Aenchen Müller*, as shown, about 2½ feet high, with rich coral-pink coloured flowers, in which the petals are somewhat convolute, the margins being rolled underneath. The flowers are much less fugitive than those of most varieties of this type. Messrs. PAUL also showed the Rambler *Tausendschön* (mentioned in the note of previous exhibit), and many others. (Silver Banksian Medal.)

Messrs. BEN. R. CANT & SONS, Colchester, exhibited *Roses*, having standard plants of Tea varieties, and pillar plants at the back, with an assortment of choice blooms in boxes and vases in the front. Mme. Jules Grolez was shown fine as a standard, and amongst the best cut blooms were those of *Marquise Litta*, Mme. Maline Soupert, *Grace Darling*, Mme. Ravat, and Papa Lambert. (Silver Flora Medal.)

Mr. GEO. MOUNT, Canterbury, again exhibited Roses in the very best style. (Silver Banksian Medal.)

Messrs. S. BIDE & SONS, Alma Nursery, Farnham, showed their new H.T. Rose Queen of Spain. The colour is a pale suffusion of rose.

Mr. W. E. WALLACE, Eaton Bray, displayed the scarlet Rose Richmond and a bowl of the pink Carnation Enchantress.

Messrs. W. CUTBUSH & SONS, Highgate Nurseries, London, N., showed some excellently-flowered plants of Carnation Robert Craig, baskets of Verbenas Princess of Wales, and F. A. Bevan, the latter a new pale-pink variety; Roses Mrs. F. W. Flight and Mrs. W. H. Cutbush; and, as a separate exhibit, a miscellaneous collection of Alpine and other hardy flowers, with dwarf, showy-flowered shrubs. A beautiful specimen of the white Rhododendron cesterianum is deserving of mention, and other good things seen were Ledum palustre, Crinodendron Hookeri, with red globular flowers on a long stalk; hardy species of Cypripediums, &c. (Silver Flora Medal.)

Messrs. H. CANNELL & SONS, Swanley, Kent, against exhibited bunches of Zonal Pelargoniums and a few of the choicer show varieties. They had also bunches of Primula obconica flowers tastefully arranged in glass vases with Adiantum Fern. (Silver Flora Medal.)

Messrs. V. N. GAUNTLETT & CO., LTD., Chiddingfold, Surrey, staged some freely flowered Azaleas, and a few hardy flowers. Azalea Omurasaki, as its name implies, is of Japanese origin; its spotted flowers are tinted a pleasing lilac-blue, an uncommon shade.

Messrs. DORRIS & CO., Rothesay, N.B., and Marks Tey, Essex, showed named varieties of Pansies and Violas, some brilliant Anemones of the Giant French strain, and improved kinds of Primula Sieboldi. (Silver Banksian Medal.)

Mr. AMOS PERRY, Hardy Plant Nursery, Enfield, Middlesex, exhibited his improved variety of Phlox canadensis, and cut spikes of Erythroniums, including E. Watsoni, E. giganteum, and E. revolutum.

Messrs. R. WALLACE & CO., Kilnfield Nurseries, Colchester, had many uncommon hardy plants in flower, and an assortment of Narcissi, Tulips, and other spring-flowering bulbs. Many interesting Fritillarias were noticed. F. recurva has red flowers borne on terminal spikes; F. libanorica is a curious green-flowered species, having a tall, many-flowered spike. We also noted Lewisia Tweedii, Iris pumila, Aubrietias, &c.

Mr. GEO. REUTHE, Keston, Kent, showed seasonable hardy plants in flower, showy trusses of Rhododendrons, and Daffodils in variety. (Bronze Flora Medal.)

Mr. MAURICE PRICHARD, Christchurch, Hants., showed an excellent batch of plants of Iris pumila, amongst other hardy flowers.

Exhibits of hardy plants were also shown by the Misses HOPKINS, Barming, Kent; Messrs. BARR & SONS, King Street, Covent Garden; the GUILDFORD HARDY PLANT NURSERY, Guildford (Bronze Flora Medal); Messrs. GEO. JACKMAN & SON, Woking, Surrey; Messrs. T. S. WARE, LTD., Feltham, Middlesex; and the Misses E. & M. KIPPING, Hutton, Essex.

Messrs. GILBERT & SON, Dyke, Bourne, Lincolnshire, staged vases of brilliant scarlet Anemones, amongst which was a large form of Anemone fulgens; the double scarlet-flowered King of Scarlets, some of the large French Anemones in several colours, with a few Fritillarias, &c.

Mr. GEO. KERSWELL, Exeter, again displayed boxes containing the beautiful blue Gentiana acaulis.

Lord HOWARD DE WALDEN, Audley End, Saffron Waldon (gr. Mr. James Vert), exhibited two dozen plants of Schizanthus Wisetonensis that exhibited good culture.

Mr. ROBERT SYDENHAM, Tenby Street, Birmingham, showed bowls of Lily-of-the-Valley, Tulips, Daffodils, and Anemones grown in moss fibre.

AWARDS OF MERIT.

Carnation Jessica.—This is another of the winter-flowering, or tree, type, but, contrary to the many self-coloured varieties that have gained Awards recently, "Jessica" has white flowers, flaked with scarlet. The blooms are of large size, somewhat flat in form, and almost scentless. Nevertheless, it is a very pretty variety. Shown by Messrs. W. CUTBUSH & SONS.

Pyrus [Cydonia] japonica Simoni.—This is not a new variety, but is certainly the deepest-coloured form of this popular plant. Shown by Lord ALDENHAM.

Narcissus Committee.

Present: H. B. May, Esq. (Chairman); and Messrs. J. T. Bennett Pöe, R. Sydenham, Rev. J. Jacobs, W. A. Milner, J. Pope, W. T. Ware, Chas. Dawson, Alex. W. J. Wilson, E. A. Bowles, P. R. Barr, W. Poupert, E. Willmott, Jas. Walker, C. T. Digby, A. Kingsmill, W. F. M. Copeland, F. W. Currey, S. Eugene Bourne, J. D. Pearson, G. Reuthe, K. W. Wallace, G. W. Leak, and Chas. H. Curtis (hon. sec.).

One of the finest collections of Narcissi ever staged at an exhibition was shown on Tuesday last by Miss E. WILLMOTT, Great Warley, Essex. This collection contained not merely the finest novelties of the day, but also many seedlings of great promise. We will mention a few of the choicer kinds, but before doing so, may refer to the fine effect made by showing many flowers of each variety with a great length of stem, and arranging them with perfect taste. We noted Duchess of Wellington, a very fine white ajax kind; Almira, poeticus; Countess of Strathmore, a handsome white ajax with creamy trumpet; Diana, a fine flower of the Leeds type; Lady Margaret Boscawen, in splendid condition; Countess Visconti, a giant bicolor of Queen of Spain type; Count Visconti, a self yellow of the same type, both distinct and beautiful; White Sergeant, a drooping, white ajax with sulphury trumpet; Rochester, a big poeticus; Sihon, a giant bicolor ajax; Will Scarlet and Lucifer, with brilliant orange scarlet crown and cup respectively; White Queen, King Alfred, Robert Berkeley (a fine bicolor of Sir Watkin form). (Gold Medal.)

Mr. J. WALKER, Thame, Oxon, had a small group, in which several of the double incomparabilis kinds were to be seen, Primrose Phoenix being one of the most notable.

Messrs. JAS. VEITCH & SONS, LTD., Chelsea, had a very good lot of flowers of such kinds as H. J. Veitch (yellow ajax), Van Waveren's Giant, Laura (rich golden ajax), Victoria, J. Pope, &c. (Silver Banksian Medal.)

Messrs. J. R. PEARSON & SONS, Lowdham, Notts, staged a choice assortment, including Lucifer, King Alfred, Lady Margaret Boscawen, Haddock's Pride (fine bicolor ajax), Florence Pearson (white ajax), Scarletta (a very striking flower), Hermione, Homespun, Cresset, and many others. All the flowers were fresh-looking and well displayed. (Silver Flora Medal.)

Mr. ALEX. M. WILSON, East Keal Manor, Spilsby, had a rich and varied collection of the choicest novelties such as Ermine, probably a Leeds variety; Ptarmigan, which appeared to be partly of Leeds and partly of Barri character; Anthea, a white ajax; Armored (Engleheartii, with richly-coloured crown); Red Eagle, and Chaffinch, both richly-coloured-crown Daffodils; Trixie, of poeticus type, and cup of lemon colour. There were some fine poeticus forms in this group. (Silver-Gilt Flora Medal.)

Mr. F. H. CHAPMAN, Rye, had a small collection of choice varieties. Baracolle, an extra large poeticus; Easter, White Lady, and Albacross were notable and good.

Rev. G. H. ENGLEHEART, Dinton, near Salisbury, had a very delightful exhibit of seedlings of poeticus, ajax, and other sections of the flower.

Messrs. BARR & SONS, Covent Garden, received a Silver Flora Medal for a rich and varied collection of mostly new and choice kinds. One of the most conspicuous, perhaps, was Masterpiece, of the Engleheartii group, the richly-coloured crown of a tone not unlike that seen in Primula Cockburniana. It is a brilliant flower, and the uniform colouring of the crown adds to its attractiveness. (Silver Flora Medal.)

Messrs. R. W. WALLACE & CO., Colchester, had a small set, in which Lemon Queen, White Queen, Diana, Dorothy Kingsmill, and Prion (a fine poeticus) were seen. (Silver Banksian Medal.)

Mr. G. REUTHE, Keston, Kent, had a collection of well-known sorts, chiefly in the Leeds and incomparabilis sections.

Messrs. HOGG & ROBERTSON, Dublin, had a large exhibit of early Tulips and choice Daffodils. (Silver-Gilt Flora Medal.)

Messrs. R. & G. CUTBERT, Southgate, staged a collection of bedding and May-flowering Tulips.

Messrs. R. H. BATH, LTD., Floral Farms, Wisbech, had a good display of the choicer Daffodils of commerce. (Silver Banksian Medal.) M. C. G. VAN TUBERGEN, Haarlem, Holland, exhibited a few Daffodil novelties.

AWARDS OF MERIT.

Tulip Le Grandeur.—A sturdy and well-known variety of fine petal-formation and substance; colour, crimson carmine. From Mr. W. T. WARE, Bath.

Narcissus Ailsa.—A white ajax Daffodil with bold trumpet and big, heavy reflexing brim; a handsome and effective flower. From Mr. E. M. CROSSFIELD, Wrexham.

Narcissus Miss Willmott.—A perfectly unique flower, said to have resulted from the crossing of N. poeticus ornatus and N. incomparabilis Gloria Mundi. It most resembles poeticus, and has its characteristic fragrance. The blossoms are some 3 inches across, and the perianth segments, of remarkable substance and finish, are broadly ovate, and, overlapping each other, give to the flower a perfectly rotund form. The crown, at first flattish, advances to the true poeticus type as the blossoms mature, and is of rich orange at the margin with a golden-coloured base. The plant is possessed of a fine stature, and it is here probably and in the large size that the influence of the incomparabilis variety may be traced. From Mr. W. T. WARE, Bath.

Orchid Committee.

Present: J. Gurney Fowler, Esq., in the chair; and Messrs. Jas. O'Brien (hon. sec.), Harry J. Veitch, De B. Crawshaw, C. J. Lucas, H. Little, W. Boxall, W. Thompson, F. Sander, W. P. Bound, A. Dye, G. F. Moore, F. J. Hanbury, W. Bolton, A. A. McBean, W. H. White, H. T. Pitt, W. Cobb, W. H. Young, F. M. Ogilvie, J. Wilson Potter, H. G. Alexander, H. A. Tracy, F. J. Thorne, and J. Charlesworth.

Sir TREVOR LAWRENCE, Bart., Burford (gr. Mr. W. H. White), exhibited a very effective group of rare species and singular hybrids. Patches of bright scarlet colour were furnished by plants of Epidendrum radicans, Epiphrontis Veitchii, and Sophronitis grandiflora; and of yellow by Oncidium concolor—of which there were two fine new forms named maculatum and macroglossum respectively; and other Oncidiums. In the centre of the exhibit was a fine specimen of Lælio-Cattleya Choletiana, and among other hybrids noted were L.-C. Adolphus, L.-C. Mozart, Miltonia Bleuana (a grand plant with 20 flowers), some pretty Epi-Lælias, the handsome Dendrobium Lowio-eburneum, and D. Dalhousie, &c. The species were represented by a beautiful specimen of Cattleya Schroderae, carrying 29 flowers, and which secured a Cultural Commendation; the new and pretty Cœlogyne Lawrenceana, Angræcum Germianum, Pleurothallis Grobyi, Sarcophilus Fitzgeraldi, Oncidium carthaginense roseum, and others seldom seen on the exhibition table. A Silver-Gilt Flora Medal was awarded the group.

Messrs. JAS. VEITCH & SONS, Royal Exotic Nursery, King's Road, Chelsea, staged an excellent group, in which the best white typical form of Odontoglossum crispum was largely represented. With these were Odontoglossum Adrianæ and others of that genus, including an example of the handsome purple-blotched O. ardentissimum Lamus, the pretty and new Dendrobium Wilsoni (introduced from China by the exhibitors), some brightly-coloured Lælia cinabarina, Oncidium sarcodes, O. Marshallianum, Lælio-Cattleya Antigone, and other hybrids, Dendrobium thrysiflorum, good Cattleya Mendelii, &c. (Silver Flora Medal.)

Messrs. SANDER & SONS, St. Albans, staged a group which included some good novelties, the best of which, Odontoglossum Prince Edward of Wales, and the fine yellow Dendrobium chrysæum giganteum secured Awards. Amongst the examples of Odontoglossum crispum were several blotched forms, the largest and darkest in its markings being O. crispum hellemense; another unnamed form was a shade of reddish orange suffused with rose after the manner of Græianum, but the full beauty of the colours was undeveloped. Odontoglossum Prince Albert ardentissimum x Wilckeanum carried handsome flowers, the basal two-thirds of the segments being coloured dark purplish brown, the tips

and the margin being cream colour; *O. excel-lens* "Golden Glory" had canary-yellow-coloured flowers, that were marked with dark purple. Other good hybrid *Odontoglossums* were also shown. Of the *Cattleyas*, *C. Schroderae*, Mrs. H. G. Moon was a large and perfectly formed blush-white flower, with an orange disc, and crimped petals and lip; *Lycaste Baringtoniae*, a pretty *L. Skinneri*, *Cattleya intermedia alba*, *Epidendrum glumaceum*, and other good things were also included in the exhibit. (Silver Flora Medal.)

Messrs. JAS. CYPHER & SONS, Cheltenham, had a well-arranged group, comprised of *Odontoglossum crispum*, *Lælia purpurata*, *Lælio-Cattleya Hyeana*, finely-flowered *Miltonia vexillaria*, *Ada aurantiaca*, &c. Amongst a number of other pretty species and hybrids was the elegant little *Odontoglossum nævium*; the scarlet *Rentanthera Imschootiana*, *Dendrobium crepidatum*, &c. (Silver Flora Medal.)

Messrs. MOORE, LTD., Rawdon, Leeds, staged a group of *Dendrobiums*, *Odontoglossums*, *Phalænopsis Luddemanniana*, *Cattleya citrina*, *Cypripediums*, &c. (Silver Banksian Medal.)

R. I. MEASURES, Esq., Camberwell (gr. Mr. Smith), staged a small group, in which several good specimens of *Cattleya Lawrenceana* were exceptionally well bloomed. The collection also included *Cymbidium Low-grinum*, *Cypripedium W. R. Lee*, *Cattleya Schroderae*, *C. Schilleriana*, *Angræcum sesquipedale*, *A. Leonis*, &c. (Silver Banksian Medal.)

J. BRADSHAW, Esq., The Grange, Southgate (gr. Mr. G. G. Whitelegge), showed *Odontoglossum Rolfeae* "Kathleen," a most remarkable and nearly unspotted variation resembling a very large *O. Pescatorei*, but with flowers of the size and shape of *O. Rolfeae*; also two flowers of *Masdevallia Veitchiana*, in which the front division of the perianth was three instead of two-lobed, as in the normal. The variety is said to be constant. A well-formed flower of *Cattleya Trianae* was also noticed.

HENRY LITTLE, Esq., Baronshalt, Twickenham (gr. Mr. Howard), showed an inflorescence of *Lælia purpurata* Miss Little, a charming, clear white variety with a slight pencilling of lilac colour on the sides of the lip.

E. ROBERTS, Esq., Park Lodge, Eltham (gr. Mr. Carr), sent *Cypripedium* Mrs. Herbert Druce, having clear, white flowers closely spotted with purple.

JEREMIAH COLMAN, Esq., Gatton Park, showed *Cattleya* William Murray "Gatton Queen," a distinct form, with a very fine mauve-purple coloured lip.

Monsieur MERTENS, Ghent, showed several good hybrid *Odontoglossums* and a spike of a very handsome blotched *O. crispum*.

DE B. CRAWSHAY, Esq., Rosefield, Sevenoaks (gr. Mr. Stables), showed *Odontoglossum hellemsense*, said to be a natural hybrid between *O. loochristiense* and *O. crispum*, with canary-yellow flowers that are marked with red-brown similarly to a good *O. Andersonianum*. Mr. CRAWSHAY also displayed the fine purple-blotched *O. crispum* Poultoni.

AWARDS.

FIRST-CLASS CERTIFICATES.

Brasso-Lælia - Cattleya Fowleri (*Cattleya Schröderae aurantiaca* × *Brasso-Lælia Mrs. Gratrix*).—A very remarkable hybrid, unique in colour and of good size and shape. The flowers are almost as large as those of *Cattleya Schröderae*, but they are thicker in substance and possess a fringed lip. The ground colour is yellow, but the sepals and petals are suffused with salmon-rose over the greater part of their surface, and the flower is also closely and beautifully veined with a darker tint of the same colour. The large disc of the lip is coloured buttercup-yellow, while the broad margin of the lip is veined and tinged with salmon-rose. The sepals show a golden hue, and the colouring throughout is indescribably beautiful.

Brasso-Cattleya Digbyano-Schröderae, Fowler's variety.—The largest and best of its class, the large labellum being finely fringed and well displayed. The flower is white, with a slight blush tint, and a large yellow disc to the lip. Both exhibited by J. GURNEY FOWLER, Esq.

Odontoglossum Prince Edward of Wales (*Rolfeae* × *Harryano-crispum*).—A very fine hybrid, embodying the good features of *O. Harryanum*, *O. crispum*, and *O. Pescatorei* and with form intermediate between its parents.

The plant carried a strong spike of white flowers, each of fine size and substance, the segments bearing heavy transverse bars and blotches of clear purple colour. From Messrs. SANDER & SONS, St. Albans.

AWARDS OF MERIT.

Brasso-Lælia Gipsy (*L. cinnabrosa* × *B.-L. Helen*).—A very pretty and distinct hybrid with the fringed lip derived from *Brassavola Digbyana* through *B.-L. Helen*, and the coppery-tinted sepals of *L. tenebrosa*, which was one of the ancestors on each side. Sepals and petals both a shade of reddish copper colour, tinged with rose. The centre of the lip is of pale yellow, with 1-inch wide margin of rose colour in front.

Lælio-Cattleya Ganymede (*L. Latona* × *C. Schröderae*).—A variety having sepals and petals blush-white, tinged with yellow, and more especially on the lower sepals. The disc of the lip is a rich orange colour; front claret-purple. A pretty novelty. This and the preceding plant were shown by Major G. L. HOLFORD.

Dendrobium chrysæum giganteum.—A large and fine form of a little-known, pretty species. The flowering stems are slender and bear large, solitary, rich yellow-coloured flowers, which possess a fringed lip. From Messrs. SANDER & SONS, St. Albans.

Lælio-Cattleya Frederick Boyle var. Kerchovea, from the Marquis de WAVRIN, Somerghem, Belgium (gr. Mr. de Geeste). Flowers white, with yellow crest to the lip and resembling a large, white *Lælia anceps*, which was one of the parents, the other being *Cattleya Trianae alba*.

BOTANICAL CERTIFICATE.

Dendrobium Wilsoni.—A pretty, fragrant species with a general resemblance to *D. moniliforme* (japonicum) but larger and taller. (Described in the *Gardeners' Chronicle*, March 24, 1906, p. 185.) The flowers are pink, with a dusky crest to the lip. This very floriferous cool-house species was introduced from China by the exhibitors, Messrs. JAS. VEITCH.

Acineta Humboldtii (var. *Colmani*).—A sparsely-spotted form of the fine old species. The whitish flowers are spotted with purple.

Fruit and Vegetable Committee.

Present: Geo. Bunyard, Esq. (Chairman); and Messrs. Jos. Cheal, W. Bates, H. Parr, A. Dean, Geo. Kelf, Jno. Lyne, J. Jacques, P. C. M. Veitch, C. G. A. Nix, W. Crump, Owen Thomas, W. H. Divers, C. Foster, A. H. Pearson, Ed. Beckett, Jas. Vert, Jos. Davies, and A. R. Allan.

A box of fruits of Strawberry Royal Sovereign was exhibited by Messrs. S. LEDSHAM & SON, 40, Foregate Street, Chester. In all, there were 18 fruits, and they weighed 2 lbs. (Cultural Commendation.)

Mr. FREDERICK COLLIS, Bollo Lane, Chiswick, again displayed his deep-coloured Rhubarb named Collis's Ruby.

Mr. S. MORTIMER, Rowledge, Farnham, Surrey, showed fruits of Tomato Sunrise, a variety that has already received an Award. Some of the clusters of fruits contained as many as 18 Tomatos, but they were not of large size.

Several seedling Apples were presented for Award, including one from the veteran raiser, Mr. C. Ross (gr. to Col. ARCHER HOUBLON, Welford Park, Newbury). The variety was named Encore; it is a large greenish-yellow fruit.

"THE AMATEUR, AND HORTICULTURAL LAW."

THE amateur and his position in respect to horticultural law formed the subject of a lecture given by Mr. H. Morgan Veitch before the afternoon meeting of the Fellows. The lecturer pointed out that in the first instance it is necessary to distinguish the rules of law relating to private gardens from those affecting the professional growers, as well as from the law relating to woods and forests and other classes of tenancy, and emphasised the fact that the private tenant must not interfere with trees planted or left standing for ornament or those which afford permanent shelter or shade. Instances were given as to the rules of law in deciding what are ornamental trees and what are timber trees. Next the rights of the tenant were defined with regard to windfalls, and trees overhanging adjoining property as well as trees

planted on or near a boundary line. The legal position of the owner of trees, the roots of which encroach on to a neighbour's land was also described.

The law relating to fixtures was next dealt with, and examples were given of the distinction between landlords' and tenants' fixtures, especially in the case of growing trees, and of greenhouses. Instances were also given of cases in which greenhouses were sometimes held to be buildings within the meaning of certain by-laws, and of others where they were not deemed to come within this distinction.

Subsequently the law relating to nuisances or annoyances caused by adjoining owners was discussed, particularly damage done to a neighbour's crops by horses, cattle, poultry, dogs, pigeons, &c.

The law relating to trespass was also explained, and instances given of the various remedies exercisable by land-owners, special distinction being made between the right to bring a criminal prosecution and the right to institute civil proceedings for an injunction and damages.

Finally, the audience was reminded of recent legislation affecting growers, and particularly certain acts passed last year, such as the Fertilisers and Fruit Stuffs Act, the Workmen's Compensation Act, and the Prevention of Corruption Act. In discussing the last-mentioned Act the speaker stated that English gardeners as a class do not act dishonestly towards their employers, but he might point out that the penalty for giving, accepting or demanding a secret commission was £500 or two years' imprisonment, or both fine and imprisonment to this extent. Unfortunately for the lecturer, he had no financial interest whatever in any nursery business. He understood that nowadays no firms of any standing would lend themselves to the giving or the offering of secret commission.

Finally, the attention of the audience was called to the Diseases of Plants and Pests Bill now before Parliament, which would enable the Board of Agriculture to take steps to check and stamp out pests and diseases affecting plant life, although compensation to the person whose stock might be destroyed need only be made by the local authority if they thought fit.

At the conclusion of the lecture the audience was invited to ask any questions on any points on which further information was desired, and several interesting questions of practical value were asked and replied to.

NATIONAL AURICULA (SOUTHERN SECTION).

APRIL 30.—The annual exhibition of Auriculas and other plants of the genus *Primula* was held at the Hall of the Royal Horticultural Society, Vincent Square, Westminster, in conjunction with the ordinary fortnightly meeting of the committees, on this date. In extent the show compared favourably with those that have been held in recent years, notwithstanding the defection of cultivators of the flower in the North of England, whose plants were not forward sufficiently to enable them to compete on equal terms with those residing in the milder South.

Novelties were fairly abundant, and these showed in some instances distinct break as regarded colour combinations.

One famous firm of Auricula growers failed to put in an appearance, viz., that of Mr. C. Turner, Slough.

COMPETITIVE CLASSES.

The strongest class was that for 24 show Auriculas, and here Mr. JAS. DOUGLAS, of Edenside Nursery, Great Bookham, won the 1st prize with finely-grown plants, distinct and clear in the paste and edges. Very fine varieties were the Abbé Liszt (green edge), G. Lightbody (grey edge), the premier bloom in the show), Acme (white edge), Olympus (grey edge), Mrs. Dodwell (white edge), Marmion (a very correct flower, possessing a black ground, white paste, and yellow tube). The flowers were a trifle rough, owing to cold weather, but the trusses were large and the foliage good. 2nd, Messrs. PHILLIPS & TAYLOR, Bracknell. Their best examples were a fine specimen of the variety Mrs. Phillips (a rich maroon self) and Mrs. Potts (a fine violet self, very handsome, even if a trifle long in the stem).

For 12 show varieties, Mr. J. DOUGLAS was placed 1st, with a vigorous lot of plants bearing large trusses and blooms. We specially noted

Dr. Hardy (green edge), Olympus (very fine in every point), Abraham Barker (green edge), Eucharis, Geo. Lightbody, Lapwing, Richard Headley (one of the finest grey edges ever raised), Mrs. Phillips, and Favourite.

The 2nd prize fell to Mr. JOHN H. WILSON, of Sheffield, whose finer plants were James Hannaford (green edge), Abraham Barker, Dr. Hardy, Heather Belle, George Rudd, &c.

The 1st prize for six show varieties was won by Mr. R. STAWARD, with fine strong plants possessing large trusses and blooms with well-defined edges and paste area. The finer examples were Lancashire Hero (gray edge), Abraham Barker, Hy. Wilson, Olympus, and R. Headley; 2nd, Mr. W. M. SHIPMAN, Altrincham, with neat plants of Mrs. Potts Gerald (self), and Shirley Hibberd (green edge); 3rd, Miss WILLMOTT, Warley Place.

The same exhibitor as in the preceding class won the 1st prize for four show varieties, with good plants of Geo. Rudd, Geo. Lightbody, Vesta, and a seedling.

SINGLE SPECIMENS.

Green-edged.—1st, Mr. J. H. WILSON, with Dr. Hardy; 2nd, Mr. STAWARD, with Mrs. Henwood; 3rd and 4th, Mr. SHIPMAN, with Abraham Barker in both cases.

Grey-edged.—Mr. SHIPMAN won 1st prize with Richard Headley, and he was also 2nd with the same variety; 3rd, Mr. STAWARD with Olympus.

White-edged.—Mr. J. T. BENNETT POE was 1st with Vesta; 2nd, Mr. SHIPMAN with Acme; 3rd, Mr. J. T. BENNETT POE with Acme; and 4th, Mr. SHIPMAN, with the same variety.

Self.—Mr. J. DOUGLAS was 2nd with Mikado, a fine, bold fancy, having a purple edge; 3rd, Mr. C. HEMNELLS with Paul Hemnells, a flower with a crimson edge; 4th, Mr. SHIPMAN with Gerald.

ALPINE AURICULAS.

In the class for twenty-four Alpine varieties, Mr. J. DOUGLAS won with a grand lot of plants bearing fine, large trusses. The exhibit contained the Premier Auricula in the show, also Argus, Janet, Ettrick, Royal Purple, Diamond Jubilee, Prime Minister (a beautiful, large flower with yellow paste and a crimson edge), and Teviotdale. Some of the plants carried three trusses of blooms on each; 2nd, Messrs. PHILLIPS & TAYLOR, with an excellent and varied exhibit, which included the varieties:—Argus, a seedling, Majestic, and Duke of York. The last-named is a very fine flower, and of correct form: the margin is coloured a deep maroon-crimson, shading to crimson; 3rd, Mr. J. H. WILSON, in whose stand there were Dean Hole, Edith Bentley, Rosy Morn, Duke of York, Forest Queen, &c., all well-formed and beautifully-coloured varieties.

Mr. JAMES DOUGLAS was again to the fore in the class for twelve Alpine varieties, having, amongst others, Glowworm (a crimson-edged flower), Urania (with a blood-red edge), Teviotdale, and Argus.

The best six Alpine varieties of Auriculas were staged by Mr. R. STAWARD. A conspicuous variety in this stand, a seedling, possessed a light purple margin and numerous blooms in the truss: Maggie (a rosy-purple self); Mr. Staward (with two shades of purple); Argus, &c.; 2nd, Mr. J. W. EUSTON (gr. Stanlake Park, Twyford); 3rd, Mr. F. W. PRICE, Beckenham.

For four Alpine varieties, Mr. EUSTON was 1st with Duke of York, Twilight, Thetis, &c.; 2nd, J. T. BENNETT POE, Esq., with Belle Ainslie (a brownish-pink), Urania, Dean Hole, and Toujours Gaie; 3rd, Mr. STAWARD.

Six seedling Alpine varieties.—1st, Mr. THOS. BARFOOT, whose plants were all of Mr. J. Douglas' seedlings, and all of crimson tints of some shade or other in the edging; 2nd, Mr. C. J. BUTLER. A bronze medal of the R.H.S. was awarded to the winner by Mr. DOUGLAS.

Twelve fancy Auriculas.—Mr. J. DOUGLAS was awarded the 1st prize for a remarkable display of plants, showing departures in the colours of the edges from existing varieties, and we may indicate in this respect the varieties Rolts' Red, Kestrel, Gaiety, Daffodil, and Innocence.

PRIMULAS.

The best twelve Primulas were shown by Mr. R. STAWARD, and included P. Sieboldii, "Magenta Queen," P. $\times$ kewensis, and P. farinosa.

Group of Primulas and Auriculas.—1st, Mr. R. STAWARD, with a number of species of

Primula and varieties of Auricula. We remarked P. japonica, P. obconica, P. $\times$ kewensis, P. calycina, P. farinosa, and P. viscosa. These and the Auriculas were bedded out in shallow wooden trays.

Twelve pots of Polyanthus.—1st, Mr. S. MORTIMER, Rowledge, Farnham, with a very floriferous lot of plants of various colours; Mr. F. Bostock (gr. to W. J. HOLLAND, Esq.), was 3rd. Mr. J. DOUGLAS, in a non-competitive exhibit, had many fine pots of these plants.

The best specimen Primrose, a large-flowered yellow variety, was shown by Mr. P. D. WILLIAMS, Lanarth, St. Hevern.

Mr. S. MORTIMER was 1st for a large collection of Primulas and varieties of Polyanthus.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

APRIL 18.—**Committee present:** Messrs. E. Ashworth (Chairman), and Messrs. R. Ashworth, Warburton, Williamson, Thorp, Parker, Thompson, Stevens, Ashton, Sander, Cypher, Keeling, Shill, Rogers, Walmsley, Ward, P. Smith, and Weathers (hon. sec.).

The meeting was an excellent one, and groups were as prominent as at previous meetings. In the competition for the Challenge Cup presented to the society for competition by Messrs. Sander and Sons, the chief competitors are A. WARBURTON, Esq., of Haslingden, and W. THOMPSON, Esq., of Stone, both of whom have scored an almost equal number of points. The deciding exhibits will be displayed on May 2, when the winner will be declared. Both gentlemen are to be highly commended for their enthusiasm during the past session. A Gold Medal was awarded W. THOMPSON, Esq., for a group of plants, and other medals for groups were given as follow:—A. WARBURTON, Esq. (Silver-Gilt Medal), Z. A. WARD, Esq. (Silver Medal), R. LE DOUX, Esq. (Silver Medal), CHARLESWORTH & Co. (Silver Medal), Mr. W. BOLTON (Bronze Medal).

First-Class Certificates were awarded Odontoglossum $\times$ hybridum var. Thompsoniae, and Cypripedium $\times$ W. Stevens, both from the gardens of W. THOMPSON, Esq.; Odontoglossum $\times$ Lambeauianum var. Warburtonianum, shown by A. WARBURTON, Esq.; O. $\times$ Wilckeanum, Ward's var., exhibited by Z. A. WARD, Esq.; and Cymbidium Sanderæ, from the nursery of Messrs. SANDER & SONS.

Awards of Merit were conferred on Odontoglossum crispum var. Rupert, O. c. var. Louisa Elizabeth, O. $\times$ bellatulum var. grandiflora, O. $\times$ Elaine var. superbum, O. crispum var. virginale, O. $\times$ Ossulstoni var. nigrum, O. $\times$ Ossulstoni var. purpureum, O. $\times$ Lambeauianum var. rubrum, Cymbidium insigne (syn. C. Sanderi), C. $\times$ l'Ansoni, Miltonia $\times$ Hyeaunum, and Cypripedium $\times$ bingleyense, Walton var., all from the gardens of W. THOMPSON, Esq.; Odontoglossum $\times$ Lambeauianum var. purpurascens, O. $\times$ amabile, O. crispum var. Victor, O. c. var. Kathleen, O. c. var. Yellow Queen, O. $\times$ Lambeauianum var. leucoglossum, Cattleya Schroderæ var. bella, C. S. var. Flora Marguerite, the eight last-named plants were shown by A. WARBURTON, Esq.; Odontoglossum $\times$ Adrianæ, Ward's var., exhibited by Z. A. WARD, Esq.; and Cypripedium niveum, Oakdale var., shown by E. ROGERSON, Esq.

HORTICULTURAL CLUB.

LECTURE ON SOIL INOCULATION.

APRIL 17.—On this date, after the usual monthly dinner of the club, presided over by Sir John Llewellyn, Bart., and attended by a goodly number of members and guests, the latter including Professors Somerville, Simpson, Farmer, and Sir Hugh Beevor, Professor Bottomley lectured on "Soil Inoculation." The lecturer, in his opening remarks, stated that although nitrogen as a gas formed the major part of the air we breathe, plants by themselves are quite incapable of utilising it as food direct, and could only do so when it was in combination with other elements, the compounds being mainly brought about by the agency of bacteria. Over every acre of land there exists in the atmosphere resting upon it no less a quantity than seventy million pounds of nitrogen gas, which, estimated at the price of nitrate of soda, would be worth £360,000 per acre. Now, it has

been known ever since Pliny's time, that leguminous plants, i.e., plants of the Pea family, such as Clover, had a peculiar faculty of living and thriving under such poor soil-conditions as starved other kinds of plants, and not only this, but that they managed somehow to enrich that soil so that good crops of other plants could be subsequently reaped, as good, indeed, as if well manured with nitrate essentials. It was, furthermore, observed that plants so gifted invariably produced a number of tubercles or knobs on the roots, the nature of which was a puzzle to the biologist, and it was only in 1886 that Prof. Marshall Ward, in England, and Prof. Hellriegel, in Germany, quite independently discovered and announced the relation between these tubercles, and the nitrogen supply by which the plants thereby benefited. They were found to be filled with microbes or bacteria, which in some inscrutable way were able to use the aerial nitrogen and supply it as nourishment to the plant they affected. The next thing was to determine whether these beneficent bacteria could be usefully introduced by inoculation to poor soils, and it was found that infusions of crushed tubercles provided material in which the organism multiplied enormously, and that even when dried to a powder the organisms retained their vitality and power to infect absolutely sterile soil for a period of two months. All that was necessary was to put a pinch of this powder into water enriched with a little nutriment, and after a few hours to wet the seed of the plants to be sown with this infusion, let them dry and sow them. In this way, directly the seed germinated, the protruding rootlet became the home of a brood of friendly microbes, who thenceforth multiplied and fed the plant and themselves simultaneously, through the agency of aerial nitrogen. In this connection, Prof. Bottomley exhibited some Pea seedlings sown in sterilised sand, and in sand watered with an infusion of nitrifying bacteria but otherwise clean. The difference even at an early stage was very marked, the extent of growth of roots and foliage was quite doubled in the latter case, and the roots of the infected plants were showing rows of nodules already. An important point appears to be that the poorest land benefits most by soil inoculation. Experiments had shown that where there is already an ample supply of nitrogenous plant food in the shape of liberal nitrate manures, the bacteria lose their energy as stimulators of plant growth. American investigators have taken up this branch of study with great energy, thus affording a marked contrast to the action of our Board of Agriculture here, which, when experimenting with material obtained from America, reported a practical failure, which was, however, due to the fact that the material was kept here for six months before a trial was made, though its vitality can only be depended upon for two. "Nitragin," one of the early materials of this kind, was in vogue for some time, but had certain defects in its preparation which led to its replacement by a triple combination of maltose, potassium phosphate, and magnesium sulphate, by the use of which, according to the directions given, cultures of the bacteria could be successfully made and utilised. Summing up, Prof. Bottomley indicated the advantages of inoculation to be:—(1) Increase of crop of leguminous plants; (2) improvement of soil for succeeding crops; and (3) increase of nitrogenous contents of plants. Cultures of Tares, for instance, without inoculation yielded 1.9 grammes of nitrogen, as compared with 3.07 grammes yielded by inoculated soil. It has been found that this capacity of bacterial association and production of nodules by nitrifying microbes is not confined to the Pea tribe, the Alder, Klamagus, Podocarpus, and Cycas being symbiotically associated with bacteria morphologically identical with those of the leguminosae, and the possibility was indicated of other plants being subject to a like influence.

In a discussion which followed the lecture, Prof. Farmer emphasised the great principle of "nothing for nothing" which ruled in Nature, and pointed out that the wonderful energy of these bacteria, which performed a task of dissociation for which man requires an electrical energy of 250 h.p., was derived from the sun through its influence on the foliage. Our most powerful explosives, such as dynamite, as pointed out by Sir H. Beevor, were simply nitrogen compressed, whose sudden liberation meant explosion, and the bacteria reversed

this operation. Mr. Cuthbertson indicated the value of soil inoculation for much of the poor land in Essex, and Prof. Bottomley replied that experiments there had already proved very successful. Mr. Druery asked the lecturer if there was any analogy between these bacteria and those which at the recent Conference on Hybridisation were shown to have symbiotic relations with Orchids. These latter, however, appear to have only power to assist the Orchid in assimilating nitrogen, not from the air, but from ammonia present in the soil; hence they do not produce tubercles, but only help the plant as indicated.

ROYAL METEOROLOGICAL.

APRIL 17.—The monthly meeting of this society was held on the above date.

A paper by Mr. R. L. Holmes on the "Phenomenal Rainfall in Suva, Fiji," August 8, 1906, was read by the Secretary, in the absence of the author. The total fall must have been fully 41 inches in about 13 hours, which he thinks surpasses anything that has been recorded in any other part of the world in so short a space of time.

Mr. R. Strachan read a paper on the "Temperature around the British Islands in relation to the Gulf Stream." This was based on observations made in the year 1906, which have been published by the Meteorological Office. Around the British coasts the temperature of the air was lowest in February, and highest in August; the temperature of the sea corresponded to these epochs with slight interruptions, having been lowest in January for the west and central; in March for the south; highest in September for the north, and in July for the east positions. The water in the Strait of Florida was about 30° warmer than the sea at the north of Scotland.

Mr. L. C. W. Bonacina also read a paper on "Weather regarded as a Function of Climate."

ROYAL SCOTTISH ARBORICULTURAL (ABERDEEN BRANCH).

THE committee of the Aberdeen branch has just issued a syllabus of competitions, open to assistant foresters in the district embraced in the branch—the counties of Aberdeen, Kincardine, and Banff. Prizes are offered for essays on forestry subjects and collections of insects. The syllabus and the conditions under which the competition is to proceed may be had from the hon. secretary of the branch, Mr. Robert Scott, solicitor, 75, Union Street, Aberdeen. The essays and collections must be lodged not later than November 1. The following is the syllabus:—No. 1.—Best collection from a local estate of insects injurious to forest trees. Each insect must be shown in its various stages of development. The collection to be neatly mounted on cards measuring 15 inches by 18 inches. The competitor must also give practical observations on the life history of each insect. No. 2.—Essay on the theory and practice of pruning forest trees. The competitor should state the object and method of pruning, and its effect on the different varieties. No. 3.—Essay or report on the practical work of forestry on the estate on which the competitor is engaged.

NURSERY AND SEED TRADE ASSOCIATION.

APRIL 25.—The annual general meeting of this association was held at its offices, 30, Wood Street, Cheapside, London, E.C.

The report of the committee presented to the meeting showed the association consisted of 184 members; that 1,041 special trade enquiries had been made last year throughout the United Kingdom for the benefit of the members; that debts amounting to £4,884 had been collected by the association and its solicitors, and that the financial position of the association was still improving.

The report contained full extracts from the recent Acts of Parliament affecting the trades represented by the association.

All the officers were re-elected.

The total receipts for the year amounted to £361 5s. 8d., and of this sum £213 3s. was received as subscriptions. After payment of all liabilities, a credit balance on the year's working of £99 5s. 8d. remains.

Obituary.

HON. MARK ROLLE.—This gentleman was so well known among horticulturists, and his gardens and Pinetum at Bicton are so representative, that his loss will be severely felt, more especially among his neighbours and dependents. His discriminating generosity and public spirit caused him to be held in the highest esteem in Devon.

ANSWERS TO CORRESPONDENTS.

* * * The Editor will be glad to receive, for consideration, large photographs of horticultural subjects, suitable for forming Supplementary Illustrations to this Journal.

ALLOTMENTS: H. A., Coventry. You had better consult a solicitor on the matters mentioned.

APPLE BUDS: A. A. W. & Son. The insects attacking your Apple shoots are one of the weevils (*Otiorynchus*). As the insect is unable to fly, if you could be sure that there were none on the tree, "grease-banding" of the stem would keep them off. These weevils generally feed at night, when they may be shaken off the trees on to white cloths, newly tarred or painted boards, or into open umbrellas. No insecticide is of any use. The Board of Agriculture and Fisheries, 4, Whitehall Place, London, S.W., publish a very useful series of leaflets on injurious insects, which may be had gratis by writing for them. The first 100 are bound together; price 6d. You will find an account of the weevils belonging to this genus in leaflet No. 2.

CATTLEYSAS DISEASED: E. M., Shrewsbury. The specimens sent are suffering from what is called "spot," or Orchid disease. It is often caused by wrong treatment, such as continuing to water heavily after the resting season has arrived. Or it may be brought about by unsuitable, badly, or irregularly heated, and insufficiently ventilated houses. If not divided at the roots occasionally, Cattleyas, under cultivation, often get affected in this way after the elapse of several years, apparently from natural decay.

CHICKWEED IN LAWN: Lawn. If the grass be kept properly and regularly cut no difficulty should be experienced in preventing the spread of this weed. Encourage the growth of the grasses at the expense of the *Cerastium* by occasional dressings of nitrate of soda, applied at the rate of one ounce to each square yard of lawn. In rich soils the grasses will crowd out everything else; in poor lands the weeds can beat the grasses. Next autumn give the land a dressing with short farm-yard or stable manure, and thus improve the fertility of the soil.

CORSICAN PINE: H. Nixon. The disfigurement on the Gooseberry shoot is the cocoon containing the chrysalis of a large moth belonging to the family *Bombycidae*, but without rearing this moth we cannot name it.

CUCUMBER CANCER: B. E. H. The rotting is caused by the development of fungus in consequence of wet lodging around the collar. Apply powdered charcoal, and when affording water to the Melon roots be careful not to wet the soil immediately near to the stem.

FIGS: *Ficus*. The fruits are attacked by a fungus consequent on variations of temperature, &c.

MELON: H. D. The collar is affected with a fungus, which generally results from decay caused by the soil immediately around the stem being kept in too damp a condition.—W. W. The fungus you send is the common Morel *Morchella esculenta*, an edible fungus.

NAMES OF PLANTS: G. A. C. *Dendrobium Pierardii* and *Odontoglossum Cervantesii*. The lip of the latter is usually more spotted than in your flower.—*Nemo*. *Choisya ternata*.—R. B. *Acacia myrtifolia*.—F. R. 1, *Kerria japonica*, double variety; 2, *Cypripedium Leeanum*, but a poor variety; 3, *Begonia nitida*; 4, *Narcissus incomparabilis* variety; 5, *Narcissus bicolor* variety; 6, *Ananassa sativa variegata*; 7, *Begonia argyrostigma*; 8, *Begonia incarnata*.—J. B. *Nigella damascina*.—G. H. *Dendrobium fimbriatum oculatum*.—J. F. *Sparmannia africana*.—F. W. J. 1, *Metrosideros floribunda*; 2, *Lotus peltorhynchus*; 3, not recognised; 4, *Episcia*

fulgida; 5, a Leguminous creeper, send when in flower; 6, *Campanula muralis*, send better specimens another time.—H. J. B. 1, *Ornithogalum nutans*; 2, *Cheiranthus Marshallii*; 3, *Narcissus incomparabilis*; 4, *Oxalis Bowiei*.—W. D. 1, *Phillyrea decora* (syn. *Vilmoriniana*); 2, a variety of *Coleus*; 3, *Acalypha Macfleckana*; 4, *Asparagus decumbens*.

PEAR LEAVES: J. L. The Pears are affected with the mite, *Phytoptus Piri*. The Peach leaves are affected with silver-leaf disease. The seed-pod is that of *Cassia fistula*.

PLUM AND PEACH: J. H. You are correct in your statement that the Plum should have two collateral ovules, only one of which, as a rule, comes to maturity, so that there is only one perfect seed. The genus *Prunus* includes *Amygdalus*, *Armeniaca*, *Cerasus*, *Lauro-cerasus*, and some other sub-genera, but if you prefer to consider *Amygdalus* as a separate genus you will find many to agree with you. The differences lie in the downy skin of the Peach (which the Nectarine has not, although it occasionally grows on the same branch as the Peach), in the deeply-furrowed stone, and in the veneration of the leaf, which is folded in the Peach, rolled in the Plum. The misplacement of the legend was corrected in our last issue.

REPORT OF THIRD INTERNATIONAL CONFERENCE ON GENETICS: J. B. C. A copy of the report will be sent free to all Fellows of the Royal Horticultural Society expressing a desire for same. If you are not a Fellow you may still obtain a copy from the Secretary, Royal Horticultural Hall, Vincent Square, Westminster, upon the payment of 15s.

ROSES: A. S. The insects infesting your Roses under glass are beetles belonging to the genus *Phyllobius*. They are very nearly allied to the weevils. Probably the best means of catching them would be to shake the bushes over an open umbrella, or pieces of board freshly painted or tarred so as to be sticky. Spraying the plants with a solution of paraffin emulsion, or with arsenate of lead or Paris Green washes would render the plants distasteful to the insects and poison them if they ate the leaves. Filling the house with hydrocyanic acid gas would probably kill them.

STRAWBERRY PLANTS: *Scotia*. The grubs you found at the roots of your Strawberries are those of one of the predaceous beetles belonging to the order *Geodephaga*, but we cannot say to what species or genus it belongs. These grubs, like the parent beetles, feed on small insects, slugs, &c., and one would naturally suppose that they were in search of their prey at the roots of your Strawberry plants, but if you found the grubs in large numbers, and no other pests, it would seem as if they were the authors of the mischief. They have very long pointed jaws which are not well adapted for feeding on vegetable substances, and we can hardly imagine that they injured your plants.

TOMATO DISEASED: H. C. See answer to H. C. in our last issue, p. 276.

VINE ROOTS: *Vinifera*. We have not yet seen the *Phylloxera*, but we are convinced it is present.

WEEDY LAWNS: J. T. As you have practised hand-weeding, and have applied top-dressings with wood ashes and short stable manure, besides making applications of lawn sand and nitrate of soda, there seems little else to recommend in order to exterminate the weeds. If the lawn is restored to a good condition and afterwards is kept closely cut and thickly covered with grasses, we do not think the seeds from the neighbouring hayfield should stand much chance of getting a foothold. In order to make a good start in your case it may be necessary to deeply trench the soil and sow it afresh with seeds.

IN A SCOTTISH MANSE GARDEN.

NOTWITHSTANDING somewhat unfavourable weather, the flowers of April have been extremely beautiful, and those of May promise to be equally fine. Some time ago I anticipated that Narcissi of every description would prove a comparative failure, but my expectations, unless, indeed, in a very few instances, have not been fulfilled. Of these, the first variety that flowered on our lawn (viz., *Narcissus Scotticus*), was nearly as florally effective as ever, while such lovely bicolors as *Empress*, *Grandis*, and the venerable *Horsfieldii* were hardly less impressive in their general effect than those which adorned our borders last year. These and many others of striking artistic beauty have been of late very picturesque in grass just opposite my study window, where, in company with *Madame de Graaff* (which should be regarded as the finest of bicolors, and not as a white variety), *Narcissus albicans*, and my namesake which might be described as an orange-coloured Emperor, have grandly naturalised. Enviroined by snowy masses of the extremely graceful *Narcissus ornatus*, whose value in such situations at this season can hardly be

over-estimated, those Daffodils have a glorious effect.

Among the greatest beauties of my garden at present are the flowering trees. The Persian Plum, *Prunus Pissardi*, has been a veritable shower of blossoms; and I am hoping that it may fruit here this season for the first time, as Mr. S. Arnott tells me it has occasionally done, under genial atmospheric conditions, at St. Mary's Isle, formerly the residence of the late Earl of Selkirk, in Kirkcudbrightshire. But at present the wind, notwithstanding frequent showers, keeps strenuously in the north, and I fear that the consequence may be some degrees of frost—a very trying experience for the evolution from flower to fruit in an Oriental tree. The hardy and generally prolific Czar Plum is not blooming so freely as usual this year; but such varieties as the Early Rivers, the Victoria, and Denniston's Superb Greengage are more florally impressive than they have been for many seasons, and that is saying much. Very beautiful at present are the Early Rivers, Black Eagle, and May Duke Cherries, of which the first-mentioned variety is much too delicate for our Scottish climate, as it seldom fruits well. The May Duke and Morello are infinitely more adapted for cultivation in Scotland. The earliest of all my Apples to flower is the variety Irish Peach, usually closely followed by the Beauty of Waltham. Here, where these Apples are greatly sheltered from adverse winds, they usually put forth their blossoms on the confines of May. The Almond has flowered but sparsely in my garden this season, and only, as I have not failed to notice, on branches facing south, probably because last summer was not sufficiently warm to mature the flowering shoots of this somewhat capricious Eastern tree. Much more reliable in our northern clime is the lovely *Pyrus malus floribundus*, a native of Japan, which I introduced into my garden about five years ago on the recommendation of my friend the late Mr. Wm. Paul. Its flowers, which are produced in the greatest profusion, much resemble those of a miniature Apple, but are even more refined. David R. Williamson, Wigtonshire.

HOW PLANTS ABSORB WATER.

PLANTS, flowers, and fruits are made up mostly of water. Chemical analysis shows that there is as much as 90lb. to 95lb. of water in every 100lb. of some of the more succulent fruits and vegetables, such as Asparagus, Cabbages, Cucumbers, Lettuce, Melons, Rhubarb, Tomatos, and Strawberries; and as much as 80lb. to 35lb. of water in every 100lb. of such fruits as Apples, Apricots, Peaches, Grapes, and Pears. Green Peas, and Beans contain 65 to 80 per cent. of water, according to their state of maturity. It is essential that the contents of the cells which enter into the structure of the growing plant should be in a half-liquid condition, in order that the nourishment and the construction-material should be carried and distributed wherever required, be it in the stem, the tender buds, the flowers, or the ripening fruit. When the cells cease to be distended with fluid sap they get flaccid and the plant wilts. Unless this flaccid state is promptly remedied by an influx of sap the cells thicken, lose their elasticity, the plant first gets stunted and finally dries up and dies.

The water necessary for plant growth is absorbed by the root hairs and hair-like rootlets issuing from the stronger roots which penetrate

the ground in search of food and moisture; it does not, however, enter into the circulation of plants quite pure, but contains in solution variable quantities of substances which plants feed upon. From these rootlets it is passed on from cell to cell by a process of diffusion, first along the larger roots, which anchor the plant to the soil, thence to the stem, on to the branches, the buds, leaves, flowers and fruit. That cell-to-cell motion, or that diffusion of the "sap," from the capillary rootlets to the tip of the branches, is quickened by evaporation, and evaporation is greatly accelerated by warmth. The evaporating organs of the plants are the leaves. These, when fanned by a breezy wind, allow a considerable amount of moisture to escape through the stomata or breathing pores. In bright sunlight these pores open to allow the admission of carbonic acid and of oxygen from the atmosphere to the working cells of the leaves. As this takes place, a good deal of the moisture which saturates the air in the intercellular spaces of the leaves escapes to the drier air outside. A vacuum is thus created, and more moisture exudes from the gorged cells to replace the amount lost through evaporation. In this manner a current of watery fluid is created from the rootlets upwards towards the branches and leaves.

The absorptive activity of the roots gives rise to a pressure which tends to force the sap upwards. In fact, root pressure, together with other forces, especially transpiration, causes the crude watery sap to ascend through the woody bundles, or framework, of the plant, and by means of these vascular bundles solutions absorbed are carried upward through all parts of the root and stem, and through the leaf-stalk, veins and veinlets to all parts of the active leaf surface. The amount of water in the soil greatly influences both the actual and relative quantity of moisture in the plant. It is a common observation that rainy, spring weather causes an increase of growth in vegetation.

The root-action of plants must operate with greater effect in a nearly saturated soil than in one which is less moist, and the young cells of a plant growing in a wet soil must be subjected to greater internal pressure than those of one growing in a comparatively dry soil—and must, as a consequence, attain greater dimensions. It is not uncommon to find fleshy roots, especially Radishes which have grown in hot-beds, split apart lengthwise. This mechanical effect is indeed commonly conjoined with others resulting from abundant nutrition, but increased bulk of a plant without corresponding increase of dry matter is doubtless in great part the consequence of large supplies of water to the roots and its vigorous osmosis into the expanding plant. J. J. Willis, Harpenden.

VEGETABLES.

SOME GOOD AUTUMN PEAS.

DURING the past few years considerable attention has been paid to the raising of late or autumn-cropping Peas, with the result that some splendid varieties, furnishing pods from August to November, now exist. All soils, however, are not suited for their culture, and the best varieties if grown in a poor land resting on gravel will yield but poor results in a hot, dry season. It would well repay the cultivator to improve such poor land, with a view to the culture of these late culinary Peas. For some years I had a poor soil to contend with in the culture of these Peas, and I planted in trenches, first placing clay or strong loam freely at the bottom of the trench. By this system I obtained fair results. Another small detail in my system of culture was that the plants were not staked—not a neat system of gardening certainly, but one

that has its merits in this case, for the shade of the haulm kept the ground cool, with the result that I gathered pods in abundance from these plants, whereas those staked were dried out just above the surface of the soil. In the North I never experienced the least trouble with late Peas, nor in the Midlands in favourable autumns, and have had good dishes of Peas in November. The adoption of trenches saves both time and labour, as late Peas grown on the flat are soon dried up if the land is light. Trenches are almost a necessity in their culture, and when the land between the trenches is given a mulching of manure, the moisture in the soil is greatly conserved.

Of the newer varieties of these Peas, Veitch's Lord Rosebery is well worth a trial, and though it may be termed a maincrop variety, it is also valuable for sowing in August and September. It grows to a height of about 4 feet, bears pods of a large size, and is altogether a vigorous grower. This latter quality makes it especially suited for late supply. Another very fine autumn variety is Sutton's Matchless Marrowfat. It attains to a height of 4 feet, and gives splendid crops. The pods are large, and enclose from 10 to 12 Peas of a dark green colour and of delicious flavour. It is a grand variety for September and October supplies. Another very similar variety is Royal Jubilee, and this being a good grower, is well adapted for culture on poor soils. A variety tried last season, and which proved itself exceptionally good, was the new Carter's Dreadnought. It grows to a height of 3 feet, and produces large pods of Peas of excellent quality. The plants were singularly free from mildew. Another addition is Carter's Quite Content, a variety that will become a great favourite for early autumn supplies. This is the result of a cross between the old, but excellent, Alderman, and the newer Edwin Beckett, and it is also an excellent variety for mid-season or later supplies.

Of older varieties, mention may be made of Michaelmas, a splendid October or even later cropper. This never failed with me to furnish a good crop, and being a dwarf grower (2½ feet) is most valuable in gardens where room is limited. Further reliable kinds are Continuity, Late Queen, and Latest of All. There are also others worth naming, such as the Gladstone, Autocrat (a splendid quality Pea of the old Ne Plus Ultra type), Sharpe's Queen, and Goldfinder, a 6-foot variety of the Ne Plus Ultra type. These are all excellent for late supplies. *G. Wythes.*

ORCHID NOTES AND GLEANINGS.

MILTONIA VEXILLARIA × ODONTOGLOSSUM CRISPUM.

UNDER the heading "My greatest deception as an Orchidist," Monsieur Lucien Linden, of Brussels, sends a long and interesting letter on the subject of the above-named cross.

After describing a few of his many pleasant surprises in new plants, M. Linden relates the care and attention paid to a pot of seedlings, the result of crossing *Miltonia vexillaria* and *Odontoglossum crispum*, and of which much was expected. The little plants died one after another until but a few were left.

Recently one of these plants flowered and its owner was disappointed to find that, in effect, it was nothing but a *Brassia*. "Ca me semble un petit *Brassia* — une fleur abominable, un *Brassia* inconnu."

Monsieur Linden states that a botanist with whom he discussed the matter suggested that it indicated that the genus *Brassia* might have originated in the crossing of *Miltonia* and *Odontoglossum*, but having many crosses between the two genera, he is hoping that they may not bear out the botanist's suggestion. A photograph or drawing of the plant and flower would be of service, for the result described is not what might have been expected.

PLANT NOTES.

THE CULTIVATION OF HYBRID COSMEAS.

So many failures have occurred in the cultivation and flowering of *Cosmeas* in Germany that cultivators have formed an unfavourable opinion concerning these plants. The reasons for this failure appear, according to Herr F. Roemer, of Quedlinburg, to be due to the seeds having been saved from plants grown in warm, dry, southern countries, and, therefore, unsuited for cultivation in climates of a very different character. The seeds germinate readily and freely, and the growth is rapid. The plants show flowers to some extent towards the middle of May; and when they are transferred to the open ground, here and there they produce

planted at 1½ feet apart in the open ground. In about one month the first blooms appear. The simple ray-like flowers measure in diameter 4.5 cm., attracting the attention of the beholder by their beauty. As cut blooms they last a long time when placed in water in a fresh condition, and may be used advantageously in the finest sorts of bouquets. The flowers are white, pink, and purple. As plants for grouping and for beds, these large-flowered, early *Cosmeas* may be most usefully employed. *F. M.*

GNIDIA POLYSTACHYA.

THE plant represented in our illustration (fig. 120) was raised from seeds in the Cambridge Botanic Gardens, where it was cultivated some years ago under the name of *Gnidia simplex*. It is a free-growing, densely-branched shrub,

FIG. 120.—GNIDIA POLYSTACHYA: FLOWERS GREENISH-YELLOW.

blossoms, and reach a height of 1½ yards, making pretty bushes, but of further flowering there is no trace. For this there are required the hot, dry air and burning sun's rays of more southern climes. Herr Roemer was as unsuccessful as other cultivators till he began saving seeds from home-grown plants, and selecting the more promising seedlings as seed parents from year to year. By this means he has secured a very free and floriferous strain, which, like other of the better species of annuals, flower from the middle of the month of June till destroyed by frost. The seed is sown in cold frames from the last week of March till the end of April. As soon as the seeds germinate, the frames in which they are housed are freely ventilated, and, when large enough to be handled readily, the plants are pricked off like *Zinnias*, &c. About the middle of May they are

attaining to a height of 6 feet or more, and in superficial appearance somewhat resembles the *Pimelia*, to which it is allied. It is of very light and graceful habit, especially when in flower, each twig being terminated by a cluster of the pretty greenish-yellow flowers, which are remarkably heterostyled. The cool greenhouse is much enhanced by the presence of this plant in early springtime. *Gnidia polystachya* is easy of cultivation: the old plants bear hard pruning, and soon afterwards become furnished with fresh young growths, whilst cuttings root readily under ordinary conditions, and quickly become useful flowering plants. It is a native of the coast regions of South Africa, and is figured in the *Botanical Magazine*, t. 8,001 (from specimens supplied from these gardens), being there mentioned as one of three forms now in cultivation. *E. J. Allard, Botanic Gardens, Cambridge.*

LEWISIAS.

ALTHOUGH a small one, the genus *Lewisia* contains some most interesting plants, and the number of species in cultivation has been increased recently by the reception at Kew of living plants of *L. Cotyledon*. The genus is confined to North-western America, and is closely allied to *Calandrinia*. Several of the species now included in the genus *Lewisia* were formerly included in that of *Calandrinia*. The first species, *L. rediviva*, was found by Capt. M. Lewis, after whom the genus was named, in the beginning of the last century. According to a monograph by Mr. B. Robinson, the number of species included is twelve, of which seven are now in cultivation, while two others, *L. brachycalyx* and *L. nevadensis*, have been cultivated, but are now lost again. They are all low-growing perennial herbs, mostly with fleshy root-stocks and leaves, and some of them have large and attractive flowers. Given a well-drained and sunny position, a few species have proved hardy in this country, and when suited make an effective display with their handsome blooms produced in quantity. The following species are those in cultivation at the present time:—

L. COLUMBIANA, Robinson. (*Calandrinia columbiana* Wats.) is found growing in clefts of rocks on Goat Mountain among other places, in Oregon. It makes a small tuft of narrow fleshy leaves, and bears panicles of small red flowers. Closely allied to *L. Leana*, it is only distinguished by having slightly pubescent leaves that are flatter on the upper side. Introduced by Mr. A. K. Bulley, of Neston.

L. COTYLEDON, Robinson (*Calandrinia Cotyledon*, Wats.).—Plants of this species, collected on the Siskiyou mountains of Northern California, have been lately sent to Kew. It was found growing on well-drained, rocky slopes, with a southern exposure, forming a rosette of leaves each 2 inches long and 1 inch broad, not unlike those of *Saxifraga Cotyledon* without the white margin. The stem, like the leaves, is fleshy, 4 inches or more high, freely branched, bearing numerous 10 petalled, rosy flowers. One of the rosettes received bore a stem with flowers, which were much damaged during the journey, but were sufficiently fresh to give one an idea as to the merit of the plant. A distinctive feature is that both bracts and sepals are fimbriated with reddish, glandular-tipped hairs. It is a promising new plant of great interest.

L. LEANA, Robinson (*Calandrinia Leana*, Porter).—Also from the Siskiyou mountains. It makes a tuft of fleshy, terete leaves 2 inches long, which are glaucous and evergreen. So far it has proved one of the hardiest, as it comes from an elevation of over 7,000 feet. The flower-stems are much branched, 6 to 9 inches high, and bear numerous, rather small white flowers streaked with red. There are only seven petals in each flower, but although small they are pretty, the whole plant having a graceful habit. This species was introduced some four or five years ago by Mr. A. K. Bulley, of Neston.

L. OPPOSITIFOLIA, Robinson (*Calandrinia oppositifolia*, Wats.; *G.C.*, 1888, iv. 601, fig. 83; *Bot. Mag.*, t. 7051).—A native of the bare, moist hill-sides of Oregon and California, this species first flowered at Kew in June, 1888. The plants were raised from seeds sent by the Harvard Botanic Garden in the previous year, but they only lived a few years, being killed during a severe winter. No seeds were ripened, and efforts to propagate by division of the root failed, so that the plant was then entirely lost. It has, however, been re-introduced lately, and distributed under the name of *Calandrinia Howelli*. When it flowered in May, 1905, it proved to be the true *Lewisia oppositifolia*, with a fleshy root, a lax tuft of oblong lanceolate fleshy leaves 3 inches long, and large, pearly-white flowers 2 inches in diameter. The flowers are produced on stems 6 to 9 inches long, and each has 10 petals.

L. PYGMÆA, Robinson (*Calandrinia pygmæa*, Gray).—Widely distributed in the Alpine regions of the Rocky Mountains. It grows only 1 to 2 inches high, with tufts of linear fleshy leaves and numerous small flowers. Plants were in cultivation recently in the nursery of the Co-operative Bees at Neston.

L. REDIVIVA, Pursh.—This name was given to this species on account of the great tenacity of life possessed by the plant. After being pressed and preserved in herbaria for two or three years, they were found to be alive, and when planted grew away and flowered. The figure in the *Bot. Mag.*, t. 5395, was drawn from such a plant, which flowered in 1863. It is a native of the Rocky Mountain region, being found along-side rivers on dry prairies. The large, fleshy roots were gathered and used by the Indians as an article of food. The plants produce tufts of fleshy leaves about 2 inches long, and will succeed in a sunny position in moist but well-drained rocky soil. The flowers are large, freely produced, and of a lovely shade of rose colour.

L. TWEEDYI, Robinson (*Calandrinia Tweedyi*, Gray).—This plant was first received at Kew from Mr. A. J. Johnson, of Columbia Nursery, Astoria, Oregon, in January, 1898, and flowered in May the same year. It was then figured in the *Bot. Mag.*, t. 7633. A native of the Alpine regions in Washington, at an elevation of 6,000 to 7,000 feet, it is quite hardy, but dislikes stagnant moisture. Forming a tuft of broad-leaved foliage, it is a handsome plant, and produces its eight-petalled flowers freely. These are 3 inches in diameter, the petals being somewhat straw coloured, passing into bright pink at the tips and along the margins. Many find a difficulty in growing this beautiful Alpine plant, and it is often lost during the winter. The best position for the plant is one exposed to full sunshine, in a mixture of loam, leaf-soil and sand, with plenty of good-sized stones mixed with the soil. An overhanging stone would afford the necessary protection from wet in winter.

Two other species of this genus have been in cultivation; one, *L. brachycalyx* in 1875, and *L. nevadensis*, from the Sierra Nevada, in 1880, but they were lost again soon after their introduction. *W. I.*

PANSIES AS BEDDING PLANTS.

THE use of Pansies and Violas for spring and early summer bedding is not so general as it should be, considering their comparative low cost, the ease with which they are successfully cultivated, and the fine effect they produce in their season of flowering. This lack of extensive use is, in a great measure, due to the short time the plants remain in bloom, compared with summer bedding plants. This is the case with plants raised in the usual way from seeds sown in August, but to procure a fine show of fresh blooms from neat bushy plants the whole of the summer through, the seeds should be sown in frames during December and January. The seedlings from this sowing should be transplanted, as soon as they are large enough, direct to the beds or borders when the spring bulbous plants are over. They should be placed about 3 inches apart, and will make excellent summer bloomers and will be in prime condition when those sown in August have exhausted themselves. Remove all seed pods from the plants, and if possible during dry weather give regular supplies of water. A mulching will considerably decrease the necessity of watering, and for the purpose procure some short stable manure such as contains a plentiful addition of sawdust, and cover the beds between the plants to the depth of an inch or so with the manure. The plants will soon grow rapidly, and, if planted close enough, cover this material. Great hindrances to the continued flowering and fresh appearance of Pansies is hot sunshine and

dry weather, and the effect of this mulching is invaluable to counteract these influences. Pansies are gross feeders and succeed best in a deep rich soil and one which does not rapidly become dry. The ground in which they are planted should therefore receive a fair quantity of well-rotted stable manure, which should be well forked in after clearing away the spring bulbs. During the last spring I saw some very fine and unique effects in bedding produced by Pansies and Violas in conjunction with Hyacinths and Tulips. The plants were placed separately between the bulbs, and their growths reached almost half-way up the stems of the bulbous flowers, and their foliage carpeted the ground, their flowers blending and contrasting very effectively with the brighter and bolder colours of the bulbs. To have Pansies in bloom at the same time as spring bulbs the seeds should be sown early in July, and the seedlings transplanted to frames for protection during winter until planted in the beds in the early spring. In the case of Pansies grown from seed it is advisable to reserve a few plants to replace any not coming true to colour, as the very best strain is liable to produce a few rogues. An ounce of good seed will furnish about 2,000 plants. It should be remembered that distinct and self colours produce by far the most admired and striking effects. *P.*

NARCISSI AT KIRKLEVINGTON HALL, YORKSHIRE.

At the present time, in the beautiful gardens and grounds of Kirklevington Hall, near Yarm-on-Tees, North Yorkshire, the residence of Mrs. Richardson, is to be seen a splendid display of Daffodils of different species and varieties. The bulbs are planted in almost every conceivable situation—in borders, in the grass, by the side of woodland walks, beneath trees, and on the lawn and pleasure grounds. The varieties are planted in different aspects, some in full exposure to the sun, and others in the shade, and the season of flowering is considerably prolonged. I cannot enumerate all the varieties grown at Kirklevington, but the following are especially beautiful.

Obvallaris is the first of the yellow trumpet Daffodils to flower, and it is planted largely in the grass. This variety is closely followed by *Golden Spur*, one of the most useful kinds for planting either in the border or in the grass. *Henry Irving* is also a very handsome flower. *Maximus*, which Mr. Cunningham, the able head gardener, considers the best in colour of this section, comes next in season with *King Alfred*, a fine rich flower, but rather expensive to purchase at present. *Emperor*, in flower at mid-season, is very largely grown in the grass and in the border, and it is in grand condition. *Glory of Leiden* is rather later in flowering, but *Abcissus* is perhaps the latest of all the yellow trumpet Daffodils.

Among the bicolors is *Princeps*, an early and useful kind grown largely at Kirklevington. *Scoticus* (Scotch Garland Lily) flowers very early and bears a small flower, and it is especially valuable for naturalising in grass. Next follows in order of flowering: *Duke of Bedford*, a splendid flower, but very expensive; *Horsfieldii*, J. B. M. Camm; *Madame Plémp*, considered by some as one of the finest in the section; *Weardale Perfection*, a lovely flower, one of the very best, but rather expensive; and *Grandis*, the very latest to flower.

The silver white trumpet Daffodils are represented by several choice kinds, such as *Princess Ida* and *W. P. Milner*, both mid-season varieties with very pretty, small flowers. Mrs. Camm is a lovely late-flowering variety, while *Madame*

de Graaff is a magnificent flower, the best of the section and rather late.

William Wilks, of the Backhousei section, has medium-sized flowers; the perianth is a pale yellow colour, and the corona is a shade of orange. It is robust in any position in the garden.

The old *Telamonius plenus* is largely grown both in the gardens and ground, and it is also used for forcing.

Queen Bess, with Blackwell, are the earliest incomparabilis. Sir Watkin follows a little later. Titian is grown in the grass, where it is very pretty. Autocrat was noticed in the grass and in the border very free flowering. It is one of the best Daffodils for supplying cut flowers. Frank Miles, in the grass in quantity, was excellent. Gwyther, in a similar situation, was also good. Queen Sophia, a very beautiful

(Mr. Cunningham says: "We think a lot of this variety; we have many thousands of it"); Flora Wilson, Mrs. C. Bowley, a very attractive flower; Dorothy Wemyss, and Golden Gem, the last-named is useful for supplying cut flowers late in the season. Nelsoni major is a fine strong grower and produces a lovely flower.

Firebrand, Blood Orange, and Little Dick, of the Burbidgei type, are grown.

The poeticus type includes Chaucer, ornatus, Cassandra, Poetarum, and the old Pheasant's Eye, which is most useful for late supply. The double white poeticus is plentiful in the grass and also the border. Mr. Cunningham has found that these do best in a damp soil, and that they are liable to be "blind" in dry ground.

Biflorus flowers rather late; it is a small flower, but useful and sweet.

The Daffodils at Kirklevington Hall are

mountainous districts, has there improved in an astonishing degree, so that the blooms, which in the type are 2½ inches across, have become in the Ceylon plant nearly double that size. The height of the foliage (which is upright instead of oblique in growth) is 30 inches; the breadth of the blossom 4 inches; the stamens, which in the original flowers are pale and insignificant, have become 1½ inch long, and of a rich shade of clear violet. The breadth of the perianth segments is more than double that of the Cape variety, and their substance has so greatly increased that they persist for three days in beauty instead of shrivelling in a few hours, as is the case with the bloom of the *Moræa* of the Cape. The yellow blotches of the type have become far larger, and are now of a rich orange, so that the colouring of the Ceylon variety, in violet, orange, and creamy-white, is remarkably beautiful, especially as the segments are handsomely "tigered" (in the improved flower) near their base with deep brown.

Seed gathered from a good type of bloom growing in Ceylon by Mrs. Johnson five years since has produced in the writer's garden a number of fine flowers, some of the seedlings being decidedly in advance of the rest in the size and beauty of their blossoms [see fig. 121]. It, therefore, appears likely that a further increase in these particulars may be expected from careful cultivation and hybridisation. This *Moræa* requires a warm greenhouse, and should be grown in a mixture of good loam, leaf-mould, and charcoal. The blossoms are produced almost continuously throughout the year. I. L. Richmond.

THE ROSARY.

CULTURE DURING MAY.

SOME of the more advanced shoots, and especially in the case of those on lightly pruned plants, have been injured by the frost and cold winds. It will, therefore, be necessary to prune again to induce a fresh growth, as the crippled wood cannot be expected to furnish perfect blooms. The maiden buds on the Briar and Manetti stock will now be growing freely, and the growths should be tied to sticks as soon as they are of sufficient length to prevent them being injured by wind. Standard Briars planted in the autumn should be attended to and made firm about their roots. Guard against the beetle that infests and eats off the young tender shoots. Seeds of the Briar sown in drills last month must not be allowed to become dry, and if necessary a good soaking of water must be given. This will aid a portion of the seeds to germinate and break through the soil, but it must be expected that a goodly proportion will not germinate until the second year.

All mulchings, except long straw and litter, should be lightly forked in the ground and a fresh top-dressing applied. There is a difference of opinion among exhibitors on the question of mulching. I have no doubt but that if it is applied at the proper time, and especially just before the flower buds begin to develop, it adds materially to the quality of the blooms. Mixed farmyard manure and soot in solution used cautiously are also to be recommended as a food. The best method of preparing this liquid is to put about 2 pecks of each of the substances into a bag and to float the bag in a 30 or 40 gallon cask of water. The fluid should be of the colour of brown brandy when it is used, and must be diluted according to circumstances, but never used neat. It may be given twice a week to actively growing plants. All growths of climbing and other Roses, either in the open or against walls and fences, should be made secure from injury by wind.

FIG. 121.—*MORÆA IRIDIODES* JOHNSONI.

variety, Stella and Stella superba all flower at about the same time. Beauty, Dorothy Yorke, Gloria Mundi, Lucifer, and Lulworth, a nice dwarf-growing variety, are among the latest in this section.

The double-flowered incomparabilis or Butter and Eggs is showy and good for massing; this and Eggs and Bacon are well-known varieties.

Amabilis and Leedsii are earliest here in their section, being closely followed by Minnie Hume, seen in quantity in the grass; and Duchess of Brabant. The later-flowering varieties in this section are: Duchess of Westminster, one of the best; Katherine Spurrell, good; Mrs. Langtry, good and free-flowering; and White Lady, a lovely flower.

Seagull is the earliest of the Barri section. All the following are much later: Conspicuous

growing in a clay soil, especially those planted in the grass. Most of those in the borders are in a sandy clay. Bone-meal as a manure is especially favoured by Mr. Cunningham. Alfred Gault, Leeds.

MORÆA IRIDIODES.

THIS Iris-like plant, a native of the Cape of Good Hope [see fig. 122], is decidedly variable, and much influenced by soil, climate and cultivation.

The typical plant is small, and its foliage does not exceed 10 inches in height, growing in fan-shaped sprays, which lean in an oblique manner from the root. The Natal variety is decidedly taller, with slightly larger flowers, and this plant, which has been naturalised in the Ceylon

The Rose maggot curls itself inside the leaves; they should be picked out and destroyed. Syringe all trees affected by this and other insect pests with a solution of soft soap, tobacco water, and quassia. Apply the insecticide during the evening and wash it off again with clear water the following morning. The frames can be removed altogether by the end of the month from plants on their own roots, and being plunged and thus kept damp at their roots and stimulated with the manure and the night dews, they will make robust plants by the end of the season. The strongest can be re-potted into 5-inch pots, but care must be taken not to unduly disturb the ball of the plant. In dry weather pot plants will require an abundance of water, except the early forced H.P.'s that will now soon be placed outside. The permanent planting of Teas and Noisettes as recommended last month can be proceeded with, assuming that the beds have been well prepared for their reception. Early forced plants of Tea Roses should be placed in a cool house and be kept rather dry at their roots. Remove all exhausted growths, and after the plants have rested top-dress them with some rich material, and well ply

FIG. 122.—*MORÆA IRIDIODES* FROM THE CAPE.
(See page 296.)

the syringe upon them, when a further crop of flowers will be secured this season. If the new shoots on established plants outside become, at the end of the month, too crowded in the middle of the bush, thin out the weaker. All the plants of H.P. Roses that were forced early should be well hardened off before being plunged or stood outside on ashes all the summer. These are often neglected, but they are invaluable for early forcing another season, as they respond much better to artificial heat than freshly potted plants taken from the ground in October; these also flower in advance of the newer plants. The autumn and spring-grafted Roses under-glass can be hardened off and plunged in beds 4 feet in width, in the open. Any that require it should be given a shift into 6-inch pots and be plunged 10 inches to 1 foot apart up to the rims of the pots. When the plants are all plunged top-dress the beds with fermented manure. If the longest and straggling growths are stopped twice during the growing season and not later than the end of July, they will make nice compact specimen plants by the autumn. J. D. G.

TREES AND SHRUBS.

THE RED OAK *QUERCUS RUBRA*.

FOR a species of Oak that will succeed on sandy, poor soils, the Red Oak is one to be highly recommended to the notice of planters either for profit or colour effect in the autumn months, and for its rapidity of growth. Trees are known, which, although they are only 50 years old, have a diameter of 18 to 20 inches. The tree begins to bear seed when about 15 years old, and this fetches good prices—100 lb. selling for £2 sterling. The wood is eagerly sought after by makers of chairs, tables, and cabinet work generally. Like Oaks in general, *Q. rubra* has produced several sports and seedling varieties, of which *Q. rubra macrophylla* is much admired. This particular variety produced a seedling with handsome, large leaves in Signor G. Sada's garden at Milan, and received the commemorative varietal name Sada in consequence. F. M.

CAMELLIAS OUT OF DOORS.

THE old belief that the Camellia is a greenhouse shrub is hard to disprove, especially to those who have never seen it outdoors in full perfection; but here we find it is quite as hardy, or even hardier, than the Bay Laurel, and certainly much more handsome. The primary use of the Camellia outdoors is as an evergreen, except in favoured spots, and we find here that the blooms are cut by spring frosts about three out of every four years. But when in flower at its best out-of-doors, the plant is even more beautiful than when flowering under glass, for the colour of the flowers and the glossiness of the leaves appear of enhanced beauty by the generally dull appearance of the other outdoor subjects growing near them. The Camellia is not a difficult plant to cultivate, its chief requirements being a fairly good soil and shelter from north and east winds. The latter provision is important to preserve the flowers from injury; the foliage is rarely, if ever, injured during ordinary winters. Camellias can be transplanted readily, and with ordinary care a specimen of almost any size can be moved with safety. The plant is impatient of fresh manure close to its roots, but it delights in ground that has been well manured for a former crop. A Camellia will often outdoors become stunted and slow of growth. When such is the case it should be cut back to the three-year-old wood, and be given a mulching of well-rotted manure. When the young shoots have grown an inch or two long the plant should be lifted and re-planted, after a dressing of leaf-mould or peat has been incorporated in the soil. If the "ball" has become hard it should be loosened, so that the roots will be able to reach the fresh soil.

The best varieties for culture out-of-doors are the single white and single red, alba plena, imbricata rubra, Monarch, and Donckelaari. The last-mentioned is the best known to me for planting outside, for the flowers are not readily injured. White flowers are disfigured by rains, but the injury is not so readily seen on the red flowers. There are some very fine specimens of Camellias in the neighbourhood of Windsor, and others at Bournemouth. J. C., Bagshot.

EPIGÆA REPENS.

THIS delightful little creeping plant is now finely in flower at the base of a large specimen of *Larix europæa*, which affords the necessary shade, and its snowy-white flowers scent the air. The plants are grown in a mixture of peat and fibrous loam, with some large sand stones. The species is a native of North America, and was introduced in 1736.

POLYGALA CHAMÆBUXUS.

THIS dwarf-growing evergreen shrub rarely exceeds 9 to 12 inches in height, but at the present time it is a conspicuous plant in the Alpine garden. It bears a profusion of fragrant yellow flowers.

AZARA MICROPHYLLA.

THE sweet smelling flowers of this evergreen are always welcome. Plants 20 feet high in the open have been profusely covered with small yellow flowers which have a fragrance resembling the odour of good chocolate. The plant grows quite freely in the stiff soil here when it is once established. W. A. Cook, *Leonardslee Gardens, Horsham*.

THE ALPINE GARDEN.

ANEMONE BLANDA VAR. SCYTHINICA.

THE above-named form of *Anemone blanda* (fig. 123) is one of the most beautiful of all spring flowering plants, and one deserving of a widely-extended cultivation. The plant is of more than ordinary value, inasmuch as its period of flowering does not coincide with the well-known typical kind, which opens its flowers of varying shades of blue and violet in warm, sunny situations in February and March, while the variety *scythinica* commences its flowering quite late in March and continues flowering through the month of April. A feature of the plant is the rich gentian-blue colour of the exterior of the petals, and seen in the bud stage this rich colouring is most effective. The inner surface of the petals is of pure white, the expanded blossoms being about the size of a crown piece.

FIG. 123.—*ANEMONE BLANDA* VAR. *SCYTHINICA*.

When in flower the plant is some 6 inches high; it has much divided and more erect and compact leafage than in the type *A. blanda*. There are usually two rows of the linear petals in this particular variety, which comes from North Kurdistan. *A. b. var. cypriana*, which is given as synonymous in the *Kew Hand-list*, is distinct in many ways, but more particularly in the broader divisions of the leaves, the obovate obtuse petals, and its much later period of flowering. As an effective garden plant, the variety *scythinica* should be placed first. All these forms of *A. blanda* should be placed where the sun can reach them, and if grown in very sandy and well-drained loam, they give but little trouble. Upon the tuberous roots of these plants are to be found nipple-like excrescences, and when dividing the roots each one of these points will presently form a plant. Young plants are easily raised from seeds, the seeds being produced in small cone-shaped heads. It is important to note, however, that these cone-shaped seed heads turn right over till the point of the cone is buried in the soil, and often it becomes completely hidden by the leaves of the plant, and the seeds, most frequently shed while comparatively green-looking, are carried away by birds. The seeds are usually sufficiently mature for gathering early in June, and should be handled with care, for they are detached by the slightest touch. E. H. Jenkins.

NOTICES OF BOOKS.

THE CONGO AND ITS FLORA.

Two publications relating to the botany of the Congo await notice. They are issued under the auspices of the Government of the Independent Congo State, and form very important additions to our knowledge of the flora of tropical Africa. They will be of great service to those engaged in the rubber industry, as well as in the plantations of coffee, cocoa, cotton and other tropical products.

Emile Laurent was a pupil of the School of Horticulture at Vilvorde; Leon Pynaert, the son of Edouard (whose memory is so cherished by his friends), was a student of the School of Horticulture at Ghent. To those two, not to mention others less known to horticulturists, students of the African flora are under great obligations.

ETUDES SUR LA FLORE DU BASSET DU MOYEN-CONGO, par E. De Wildeman, vol. ii., fasc. i., plates i.-xxxv.

This consists of an enumeration with descriptions and quarto plates of various new and interesting plants from the Belgian Congo. The descriptions have been prepared by M. De Wildeman. Several of the plants are in cultivation in the Brussels Botanic Garden, or that at Laeken, such as *Crinum Laurentii*, *Polystachya polychæta*, *Listrostachys Pynaertii*, and others. *Barteria fistulosa*, Masters, is remarkable for its hollow stems, which are the abode of ants endowed with such stinging power that no one having once obtained a specimen will care to collect another.

MISSION EMILE LAURENT, fasc. iv., pp. ix.-cxx. et 355-450; pl. cvii.-cxlii.

This fascicle contains a biographical notice of the gardener-botanist of whom not only his countrymen but his scientific colleagues of every civilised country deplore the loss. It would be difficult, if not impossible, to raise a better memorial than is afforded by this publication. Not only are there many plants enumerated and figured, but numerous very interesting photographic reproductions of scenery, plant distribution, and the like serve to give the stay-at-home naturalist a good idea of the vegetation of the country and of the conditions under which it grows. The text is prepared by M. De Wildeman, a sure guarantee of care and ability.

A Royal decree in Brussels has authorised the Belgian Ministers of the Interior and of Public Instruction to accept for the Royal Academy a sum of 15,000 francs, which was collected by the Comité Laurent, to provide a biennial prize of 900 francs for an award to be known as the "Prix Emile Laurent." The prize will be awarded alternately, first, to the Belgian author or authors contributing the best work on the flora or vegetable productions of the Congo; second, to the Belgian author or authors for the best work on the agricultural and horticultural applications of such plants.

The Week's Work.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower to Sir Trevor Lawrence, Bart., Burford, Surrey.

Phalænopsis.—Such species as *P. aphrodite*, *P. amabilis*, *P. Schilleriana*, *P. Stuartiana*, and *P. Sanderiana* will in some cases have completed flowering. The plants frequently produce secondary spikes, but it is not advisable to allow these spikes to grow, as they would have the effect of weakening the plant. Any fresh spikes that may appear should, therefore, be at once pinched off. The *P. Rimestadtiana* varieties are now showing strong spikes of bloom. Expose the plants to all the light possible without actual sunshine, and keep their surroundings fairly moist. Any plants which have just passed out of bloom and require fresh receptacles should be placed in fresh teak-wood baskets. The roots are very liable to suffer injury during their removal from whatever material they may be clinging to, therefore if the baskets in which they are growing are already large enough, and the plants are in a thriving condition, they may be treated as follows:—Carefully work out all the old potting materials, and with the syringe and tepid water thoroughly wash the basket; cut out all dead roots, and then replace the

drainage material, which should be to three-fourths the depth of the basket, and fill up with sphagnum-moss and finely-broken crocks, taking care to press these moderately firm around the base of the plant. Cover the whole with freshly-gathered sphagnum-moss. Such plants as have to be placed in fresh receptacles should be removed from the old baskets as carefully as possible. For the first few weeks after the operation, the plants will require very careful watering; keep the surface of the moss and the sides of the basket well sprayed, but not so heavily as to cause saturation. When young roots begin to extend over the wood of the basket, the sprayer may be more frequently employed. When in full growth, *Phalænopsis* require an atmosphere that is nearly always at saturation point, and at the same time plenty of air should be admitted by means of the top ventilators. Where no separate house is provided for their cultivation, the best position for them is on the shady, or north side, of the East Indian house, or the ordinary plant stove. Such species as *P. Sumatrana*, *P. violacea*, *P. Marie*, *P. speciosa*, *P. tetraspis*, *P. Lueddemanniana*, and *P. fasciata* should be placed together at one end of the house, in order that extra shade may be provided for them, as their green foliage is very easily injured by the sun. Sponge the leaves over periodically to free them from all dust and insects.

PLANTS UNDER GLASS.

By J. G. WESTON, Gardener to H. J. KING, Esq., Eastwell Park, Kent.

Plumbago rosea coccinea superba.—This plant is worth inclusion in any collection of winter-flowering plants, its light, graceful sprays of flowers being particularly elegant for all decorative purposes. Although its lasting qualities are not of the best, the profusion of successional flowers in a measure atones for this defect. If the growths of the old plants were shortened after the winter, and the plants returned to a warm house, they will have made shoots by this time suitable for use as cuttings. These should be prepared for propagating purposes without delay, and after insertion in sandy soil be placed in the propagating frame. When roots have been made, pot the plants singly, using light, sandy soil, and cultivate them all the summer in an intermediate temperature, pinching out the points of the shoots once or twice. Shade the plants lightly during the hottest part of the day, and syringe well and frequently during the growing season. Reduce the atmospheric moisture, and admit more air to the structure at the end of the summer, in order that the growths may be better mature. Let the plants flower in a fairly dry atmosphere of a minimum temperature of 60 degrees.

Gardenias.—Good "cuttings" being now plentiful, a batch should be taken off and inserted in light, sandy soil in pots, placing the pots in a hot frame. Stout young shoots will form the best cuttings. After the little plants are rooted and have been potted once, pinch the points out of the shoots to induce a bushy habit. Gardenias, when in full growth, require stove temperature and much atmospheric moisture. Older plants may be repotted, using a compost consisting of equal parts of turfy-loam, peat, and leaf-soil, with sand and charcoal added. Keep a sharp look-out for Mealy-bug and Thrips, to attacks of which Gardenias are very susceptible.

Medeola asparagoides.—Where decorative work has to be undertaken, a good batch of this plant is indispensable. Young plants grown from seeds sown in January are now making nice growth, and should be potted on as required before the roots become pot-bound, using a compost of two parts loam, one of manure from a spent mushroom-bed, and one part of leaf-soil, adding some sand. When in full growth this plant requires plentiful supplies of water at the root, and may be afforded regular supplies of a stimulant, whether in the form of natural manure and soot water, or chemical plant manure. Rather heavy shading is desirable, as if exposed to direct sunlight the plants lose that pale green tint so much admired. A convenient way of training the growths is to use green Carnation twine. The growths will climb round these, and when desired the strings may be cut with the growths, and they will be unnoticed amongst the leaves, &c., when used for decorative purposes.

FRUITS UNDER GLASS.

By ALEXANDER KIRK, Gardener to J. THOMSON PATON, Esq., Norwood, Alloa, Clackmannanshire.

The Orchard house.—Fruit trees in pots, including Apples, Pears, and Plums, having now set their fruits, the thinning of the latter must at once be attended to. Remove all the side fruits from clusters, but do so at intervals of a few days, as fruit-thinning is best done by degrees. Those on spurs pointing to the centre of the tree may be first removed, leaving only those which are well exposed to the light. A second thinning will be required when the fruits are of the size of a Filbert, finally leaving only the best-formed fruits to develop. Do not over-crop the trees, especially if fruits of the best quality are required. Syringe the trees both night and morning, and admit abundant supplies of fresh air daily, also at night-time, when the weather is favourable. In the case of young trees allow the growths to extend considerably before pinching them. Shoots on older trees may be stopped more closely. An important item in the culture of fruit trees in pots is to top-dress each plant when actively growing with a mixture of fresh loam, chemical manure, or horse-droppings. Look for and capture caterpillars, which may be found in curled leaves, destroying any that can be found, by squeezing between the thumb and the finger.

Melons.—Attend to the watering of the borders, the tying of the growths, and the thinning of the fruits. Two, or, at the most, three, fruits will be ample for each plant to carry. Do not allow one fruit on any plant to swell in advance of the others on the same plant. Pinch strong growths, and allow the lateral shoots to extend throughout the season of growth: this will necessitate active root growth until the fruits are ripe. As soon as the fruits commence to colour afford ventilation freely, also keep the atmosphere of the structure in which they are growing much drier, and give less water at the roots. Afford a top-dressing of fresh loam or long manure for the purpose of furnishing food and keeping the border moist. Sow seeds for raising succession plants.

Later batches of Melon plants in 6-inch pots should now be planted into frames or pits previously prepared for them. Maintain a bottom heat of 80° in the pits, and keep the atmosphere moist by damping the paths with tepid water. Close the structure early in the afternoon when the inside temperature registers 90°. The temperature of the Melon pit by day without sunshine should range from 78° to 80°, and at night-time 70° must be maintained.

Cucumbers and Melons may now be planted into box frames containing leaves and horse litter which will furnish a bottom heat of 70°. Allow two plants to each light, and plant on the top of a ridge of soil, and close to the glass. Stop the ends of the main shoots, give a good watering with tepid water, and keep the frame close for a few days after planting.

THE APIARY.

By CHLORIS.

Wasps.—Bee-keepers and gardeners are well aware of the damage done by wasps later in the season. Every queen wasp now killed means one nest less later. Queens may often be seen on buds, and old boards nibbling off pieces with which to build their nests. A piece of light flat board is very useful for the purpose of catching them, and brings them to the ground with ease. Nests are easily destroyed later by placing a piece of cyanide of potassium at the mouth of the hole by which the wasps enter the ground, and wetting it with a garden watering pot with a fine rose, once or twice, at the same time removing the dead wasps with a stick.

Bees and fruit.—In California Cherry orchards were of no value until an apiary was established in their midst, and in this country, since the late Mr. Gladstone recommended fruit farming and jam-making as an industry, much greater quantities of fruit have been secured, where bees have been kept near the trees, and not only has there been greater fruitfulness, but £200 to £300 has been made from the sale of honey and wax. When fruit trees are in bloom there are more bees on the wing than any other insects. One hive is generally sufficient for an acre of ground.

THE HARDY FRUIT GARDEN.

By J. MAYNE, Gardener to LORD CLINTON, Bilton, East Devon.

Current bushes.—Green and black aphids are common enemies of these plants, and if any are present on the bushes they should be syringed with quassia extract, using half a pint to four gallons of water. Well stir the liquid before applying it, which should be done about 5 p.m. in the day, or later. Give the bushes a good cleansing with the garden engine next morning. The Gooseberry Saw-fly sometimes infests Currant bushes, especially if the latter are planted near Gooseberries. They should be destroyed, as recommended in last week's Calendar. All swollen buds on Black Currant shoots must be picked off and burnt. The Black Currant is later coming into flower than the Red and White varieties, and therefore the syringing in that case must be deferred until the berries are formed.

Pears.—The recent hailstorms have caused much injury to these trees in many parts of the country. Young fruits damaged by the Pear-midge quickly turn black, and later fall to the ground; these should be picked off and burnt as soon as they are detected. All protective material should be removed immediately the trees have passed out of flower.

Figs.—If milder weather sets in, growth will be quickly made, and many shoots will need to be removed. Rub out any ill-placed shoots while in a small state; this system is much better than the use of the knife later. Any main branches that have reached their allotted space should have the point of the main shoot pinched out at the fourth leaf. Branches required for extension need no stopping, as only one crop of fruit is possible from trees in the open.

Hoeing.—Should the weather continue moist, it will be wise to hoe and rake away all weeds, choosing a dry day if possible for the operation. Avoid removing too many of the smaller stones with the weeds, as the stones may have a beneficial influence on the soil, especially if it is of a heavy or adhesive character. Many common and troublesome weeds produce seeds when in quite a young state, and their seeds are easily dispersed by wind all over the garden.

PUBLIC PARKS AND GARDENS.

By W. W. PETTIGREW, Superintendent of the Parks and Open Spaces in the City of Cardiff.

Summer bedding.—The season for putting out summer bedding plants is approaching, and most gardeners have probably decided already what their various arrangements for the season are to be. Few subjects, as a rule, cause more anxiety to gardeners in general and park superintendents in particular, than the question of summer bedding. In many towns this is often the feature by which the public judge the merits of their parks, hence it is but natural that much time and care are bestowed by superintendents upon the preparations for this work. Try as one will, it is exceedingly difficult to break away even in such a matter as summer bedding, from old forms and customs. Originality of arrangement, or in the combination of various species of plants that would be in keeping with modern taste, in the furnishing of flower beds is exceedingly difficult of attainment, and it is no uncommon thing to see a design planted year after year in the same manner, without the slightest variation either in arrangement or material. As the whole system of bedding out is at best somewhat monotonous in character, every effort should be made to vary it as much as possible, so that at least the same arrangement may not be used two consecutive seasons in the same beds.

Pelargoniums.—Viewed from whatever standpoint one chooses, it must be admitted that our system of bedding out is artificial in the extreme, and the fashion of using half hardy plants of the Pelargonium type so freely, makes it, in addition, a very expensive form of garden adornment. Notwithstanding this, however, long association inclines most of us to regard Pelargonium as an indispensable part of garden arrangement. Closely-trimmed and well-kept lawns, studded about with numerous and diversely-shaped beds filled with brightly-coloured flowering or foliage plants, are usually associated with the idea of high-class gardens and public parks, and so long as this is regarded as the ideal of the English flower garden, so long will those who have to satisfy the public taste continue the system.

Succession of flowers.—In public parks it is the aim to have some or other of the flower beds or borders bright and showy from the earliest to the latest part of the season, so that it is necessary to utilise a great number of different kinds of plants to maintain a succession of bloom. When much bedding out is done in a park, it is advisable to arrange that the whole of the floral designs are not at their best at one time.

Carpet-bedding.—If the use of Pelargoniums, Fuchsias, Dahlias, Begonias, and Calceolarias for bedding purposes is characterised as artificial, how much more so is the use of Alternantheras, &c., for the purposes of carpet-bedding. Whatever may be urged against the formality of ordinary bedding, the plants are at least allowed to develop and show some of their natural characteristics—an argument which cannot be advanced in favour of all those used for carpet-bedding. This style of using plants is the most expensive, unnatural, and useless carried out under the name of gardening, and yet, as it appeals to the innate love of the curious which is possessed by the great majority of visitors, carpet-bedding finds a place in nearly every public park of any size throughout the country. True plant-lovers cannot tolerate the puerile and meaningless imitations of clocks, rolls of carpet, and church windows, which some sections of the community regard as little short of the acme of horticultural skill. It is undoubtedly a very great temptation to those in charge of parks to pander to public taste in this matter, but not only should this be avoided, but an effort should be made to educate public taste into better channels.

THE KITCHEN GARDEN.

By WILLIAM H. HONESS, Gardener to C. COMBE, Esq., Cobham Park, Surrey.

Onions.—Plants raised from seeds sown in heat early in the year, and that were subsequently pricked off, should be in a well-hardened condition and ready for planting out without delay. It is usual to do this work a fortnight or so earlier than the present time, but as rough, northerly winds and sharp frosts have been so prevalent throughout April, there would have been no advantage gained had tenderly-reared vegetables been planted in the open at an earlier date. If extra large bulbs are required, it will be well to put the plants at 9 to 12 inches apart in the rows, and the rows should be drawn at 15 inches apart. If the weather is showery at the time of planting, no further watering will be necessary, but otherwise a good watering should be applied. It is assumed the ground for this particular crop was thoroughly prepared early in the winter, and that it has mellowed down into a friable condition. Lift the plants with as much soil attached to the roots as possible, and plant them as shallow in the soil as practicable and consistent with making them firm.

Winter Onions.—These will now be starting nicely into growth, and should be afforded a sprinkling of nitrate of soda, which should be well worked into the soil with the hoe. If three dressings are given at intervals of a fortnight, and then alternated with a mixture composed of dressings of kainit 3 lb. and superphosphate 5 lb. per 40 square yards, a great improvement will be observed.

Beet.—Plants raised from the small sowings made early in the season will now be making good progress. Continue to give these the protection of old Yew boughs laid on the ground; any that are partially bare through the leaves withering and falling off will answer this purpose well, as they will afford the amount of protection that is necessary, but at the same time admit sufficient light and air to the young plants. No advantage is gained by sowing seeds for the main crop before this date, as for general purposes large Beetroots, or any that might be described as coarse, are to be avoided. The ground for this crop should be tilled and prepared in the winter, and although this cannot always be arranged, under no circumstances should the main crop varieties be sown on recently-manured ground. The same treatment is necessary for Carrots, Parsnips, and most of the other root crops. The seed should be sown in drills not more than 2 inches deep, and drawn at distances of 15 to 18 inches apart, according to the different varieties, eventually thinning out the young plants until they are from 6 to 9 inches apart.

Early Potatoes.—Fresh plants will appear above the surface of the soil every day, and they will require to be closely watched that sufficient soil may be drawn up to them to protect the young growths from frosts. The system of propagation by taking off the young growths, which was practised a few years ago when the variety Northern Star was being boomed, does not appear to be a success, as plants so raised, including those varieties advertised as being capable of resisting disease, appear to be so weakened by the process, that tubers grown from the plants have been attacked in the following season to an unusual extent. Additional plantings of Potato tubers should still be made, and might be continued for some time to come, as late plantings would materially lengthen the season for "new" Potatoes, which are so generally appreciated at any time of the year.

THE FLOWER GARDEN.

By A. C. BARTLETT, Gardener to Mrs. FORD, Pencarrow, Cornwall.

Herbaceous plants.—Both the tree, or moutan, and the herbaceous Pæonies should now be afforded some support against wind. The main branches of the tree varieties should be tied to stakes. In respect to most of the older varieties of the herbaceous Pæony, it will suffice to tie up the whole plant, taking care not to bunch it too tightly. The flowers of the newer sorts are so large and heavy that they must be tied separately. Thin out the weak growths of the perennial Sunflowers, Delphiniums, Lupins, &c. As the Arabis and Aubrietias finish flowering they must in many cases be restricted or they will be apt to grow out of bounds. Use the Dutch hoe frequently to keep down weeds, and assist in the aeration of the soil.

Pentstemons and perennial Phloxes should be planted out in their flowering quarters, which were prepared last month. Pentstemon seed recently sown in heat has germinated freely. After the seedlings have recovered from the check of pricking off they should be gradually removed to cooler conditions.

Border Chrysanthemums may also be planted out. Plant them firmly, or the roots of the plants will not only dry quickly, but the shoots will be weak and spindly. When the plants are established pinch out the tops of the leading shoots, and should dry weather set in afford a mulching.

Bedding Begonias.—Both the tuberous and fibrous-rooted varieties should now be sufficiently advanced to be transferred to cold frames. Place the plants on a cool ash-bottom, setting them well apart. After the first two or three days the lights should be removed whenever the weather will allow, the object now being to harden the plants before they are planted in the flower beds. For the first week it will be wise to cover the frames at night.

Narcissus poeticus plenius.—The tips of the flower sheaths should be snipped with a pair of scissors, as a precaution against "blind" flowers.

Cacti.—As the winter frames will be removed in a fortnight, the lights should be taken off by day and tilted at night whenever weather permits. If the plants are dry at the root, give them a copious watering on a fine morning with chilled water. The surface pieces of sandstone should be taken away and replaced by freshly-broken stone, first stirring the surface soil and removing all weeds. If a sheltered corner can be had, well exposed to the sun, and a raised rockery made, many species of Cacti may be grown out-of-doors unprotected for a great part of the year. As winter damp, rather than cold, is the greatest enemy of these plants, some preparations should be made for keeping them dry during winter—preferably by means of portable frames. Ample drainage must be provided, and a soil composed largely of fibrous loam, with enough broken rubble to keep it open. Pieces of some porous substance, such as soft sandstone, old red brick, or charcoal should be placed around the plants to absorb superfluous moisture. As the nucleus of a collection, the following kinds can be recommended:—*Cereus phœniceus*, *C. Fendleri*, *C. Engelmanni*, *C. gonacanthus*, *Echinocactus Pentlandi*, *E. Simpsoni*, *Mammillaria vivipara*, *Opuntia arborescens*, *O. brachyarthra*, *O. camanchica*, *O. c. minor*, *O. Piccolomini*, *O. Rafinesquii*, and *O. vulgaris*.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Special Notice to Correspondents.—The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.

Illustrations.—The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but he cannot be responsible for loss or injury.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY, MAY 14—

Roy. Hort. Soc. Coms. meet.
British Gard. Assoc. Ex. Council meet.

SATURDAY, MAY 18—German Gardeners' Soc. meet.

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich—52° 8'.

ACTUAL TEMPERATURES:—

LONDON.—Wednesday, May 8 (6 P.M.): Max. 65°; Min. 49°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden; London.—Thursday, May 9 (10 A.M.): Bar. 29.8; Temp. 56°; Weather—Slight rain.

PROVINCES.—Wednesday, May 8 (6 P.M.): Max. 51°; Cornwall and Ireland S.; Min. 30°; Folkestone.

SALES FOR THE ENSUING WEEK.

WEDNESDAY—

Gladiolus, Montbretias, Begonias, Lilliums, Stove and Greenhouse Plants, Palms, Bayas, &c., at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.

THURSDAY—

Sale by tender of Warwick Road Nurseries, Bristol. Auctioneer, Mr. Albert Ford, Albion Chambers, Bristol. Tenders to be received before 12 o'clock noon.

FRIDAY—

Choice Imported and Established Orchids in variety. Orchids in flower and bud, at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.45.

Colonel Prain presided at a recent meeting of the Society of Arts, when the subject of cultivation of trees and plants yielding rubber was brought forward by Mr. Herbert Wright. In the course of his remarks, the Chairman (the Director of the Royal Gardens, Kew) uttered a warning note as to the possibility of epidemic disease breaking out in the plantations, as it had done in the case of coffee in Ceylon. When large areas are planted with trees or plants generally in juxtaposition, it is evident that the conditions are eminently favourable for the spread of disease. The danger may be averted or minimised by the precautions advised by a competent pathologist, and by the care and supervision exercised by the cultivator.

In connection with the supply of rubber it should be borne in mind that the production of caoutchouc by chemical means, already proved to be possible, may ultimately compete with the natural product. Again, there is the risk of over-production, as has happened in the case of the Cinchona. More than one speaker, we are glad to note, recognised the value of the services rendered by Kew in the extension of the rubber industry in the various colonies and dependencies where the cultivation is possible. Manufacturers and brokers concurred in expressing their thanks to Kew and the Colonial Office, because it was to their efforts that the wonderful success which had been achieved by

the industry was due. To Sir William Thiselton-Dyer much credit is also due for his work in this direction during his directorate. Very few of those who go to Kew to "look at the flowers" or gape at the water-fowl have any conception of the work done in acquiring and raising plants of industrial or economic importance, in distributing them, and in promoting their cultivation in the Colonies.

Mr. Wright's paper contains an admirable summary of our knowledge as to the commercial potentialities of rubber cultivation, and the plants furnishing the valued juice in various tropical countries. From this latter point of view, Mr. Wright emphasises the necessity for correctly identifying the valuable caoutchouc-producing species from others similar in appearance, perhaps, but less important, or not important at all, from the point of view of rubber production. Here, again, the value of the herbarium at Kew is illustrated. Details concerning the collection and preparation of the rubber were also given by Mr. Wright, whose communication is therefore one of great value to all concerned in the industry, as containing in short compass a classified summary of what is known of rubber in its various aspects.

With regard to the durability of rubber, one of the speakers in the discussion that ensued on Mr. Wright's paper stated that "the archway under Euston Station was paved 18 years ago with a rubber composition, and during that time it had only worn to the small extent of five-eighths of an inch. It had been clearly demonstrated that, compared with wood, asphalt, and pavings of that description, rubber worked out much cheaper in the long run, because of its enormous durability."

OUR SUPPLEMENTARY ILLUSTRATION is a reproduction from a photograph taken by Mr. GREGORY in the exceedingly interesting gardens of Sir EDMUND LODER, Bart., at Leonardslee, near Horsham, in Sussex. The view represented is one in a portion of the grounds known as the American Garden, which is planted with a rich collection of Rhododendrons, including the less hardy species; Ericas, Ledum, Camellias, Gaultherias, Kalmias, and other flowering shrubs. The stems of many of the indigenous trees are gay in June and July with the flowers of rambling varieties of Roses, but as a foil to the extraordinary amount of colour furnished by the Rhododendrons and Roses there are grand clumps of Bamboo and a large number of hardy Palms [Trachycarpus]. Few gardens, indeed, possess so many hardy Palms as may be seen at Leonardslee, there being about 400 plants in healthy growth. As the photograph was taken when the deciduous trees were leafless, the fine effect of the Palms on the landscape in winter is well shown in the illustration. A detailed account of the Leonardslee Gardens, which are in the care of Mr. W. A. COOK, was published in these pages on Oct. 13 and Oct. 28, 1906.

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the committees will be held in the Society's Hall, Vincent Square, Westminster, on Tuesday next, May 14. In the afternoon at three o'clock a lecture will be delivered on "Photographs of Flowers."

HORTICULTURAL CLUB.—The next house dinner of the club will take place on Tuesday, May 14, at 6 p.m., at the Hotel Windsor, when Mr. P. ANDERSON GRAHAM will deliver a lecture on "Small Holdings."

THE ROSE SHOW.—Some of our readers will be glad to be reminded that the exhibition held annually by the National Rose Society will be open in the Royal Botanic Gardens, Regent's Park, on July 4. All applications for space must be made to the secretary before the end of June.

AN APPRECIATION OF SIR JOSEPH HOOKER.—The American Florist for April 20 contains a brief biography and a portrait of Sir JOSEPH HOOKER, in which due mention is made of his long and valuable services to botany. Sir JOSEPH HOOKER attains his ninetieth birthday this summer, and the "veteran English botanist is still straight and active and a keen worker."

THE OXFORD PAGEANT.—A prospectus has reached us of the Pageant which it is proposed to hold at Oxford during the last three days of June (except Sunday, 30th) and the first three days of July. The commemoration will, of course, be historical in character, and is in aid of the Radcliffe Infirmary and other charities. The prospectus contains some interesting pictures of Oxford in the past.

"PUNCH" PICTURES FOR PARIS.—Our famous contemporary has recently exhibited a collection of upwards of 100 drawings, executed by the more famous living Punch artists, and which are to form a portion of the forthcoming exhibition at the Salon des Artistes Humoristes, to be held from the 15th instant to June 30 in Paris. The drawings were on view in the Punch dining-room, where the famous weekly dinner is held.

HORTICULTURE IN EGYPT.—The EARL OF CROMER, late British Agent and Consul-General, in his annual report lately received at the Foreign Office, remarks that there can be no doubt there is much land in Egypt which is singularly suitable for market gardening, and which could very profitably be devoted to that purpose; also, that many trees could be grown on land which is practically useless for any other purpose. It has now been decided to grant a Government subvention to the Agricultural Society at Alexandria on the condition that the money shall be used for horticultural purposes. For the rest of Egypt, a new horticultural society has been formed, entitled "The Commercial Horticultural Society of Egypt," with Prince HUSSEIN PASHA KIAMIL as president. The Government has assisted this society with a considerable subvention, and has given it further facilities as regards the use of land, &c. As a commencement, two gardens (one of some 5 acres and the other smaller) have been started in the immediate vicinity of Cairo, and an English secretary, Mr. T. BROWN, has been engaged to carry on the work of the society, more especially with regard to making experiments as to what varieties of vegetables and fruits can be most profitably grown in the country. He is further charged with the education of a certain number of young Egyptians in all matters pertaining to his profession, such as vegetable cultivation, grafting of fruit and other trees, and other matters which are little understood in Egypt. It is hoped eventually to start experimental gardens in all the big provincial centres, where not only experiments will be carried out, but ocular demonstrations given to the cultivators as to the possibilities of Egypt in this direction. All who have paid attention to this subject lay much stress on ocular demonstration as by far the best, if not the only, way of convincing the Egyptian cultivator that horticulture can be successfully and profitably carried out. The encouragement of arboriculture will also form an important duty of the new society. Later, should the society's labours be crowned with success, it will act as the middleman between the producer and the merchants until an adequate connection has been established between the two.

Photo by J. Gregory.

THE AMERICAN GARDEN AT LEONARDSLEE, HORSHAM, IN JANUARY,
SHOWING HARDY PALMS, ETC.

Temple Press Ltd., Printers, 7-15, Rosebery Avenue, London, E.C.

FLORAL DESIGNS.—Mr. W. D. WILTSHIRE has re-published in pamphlet form and with additions some designs for bouquets and wreaths that have been given in the *Fruit, Flower, and Vegetable Trades' Journal*. He gives many reproductions, from photographs, of floral arrangements of all sizes from button-holes to elaborate funeral devices. Many of the latter demand not merely a wealth of flowers, but a special faculty for their construction. It is impossible to teach the whole of the wreath-maker's art in writing, but the pictures provide many suggestions, and there are some useful hints to aid the amateur florist in constructing decorations. This amateur industry affords employment to many workers who are, naturally, desirous that it shall remain popular. That anchors, harps, and other devices should be constructed of flowers is not in accordance with good taste.

A CONCISE HANDBOOK OF GARDEN ANNUAL AND BIENNIAL PLANTS. By C. M. A. PEAKE. (METHUEN & Co., 36, Essex Street, W.C.).—This little book is one of a series, and therefore uniform with others and subject to certain restrictions as to space. Mr. PEAKE wisely makes special mention of desirable plants, whether familiar or not, and passes lightly over certain popular but comparatively worthless varieties. The notes upon annuals and biennials and their cultivation are followed by a useful alphabetical list, with descriptions and comments where necessary. Many illustrations and a full index further assist the enquirer after knowledge, and the whole makes a handy guide that may be trusted as regards the matters of which it treats.

FOOD-REQUIREMENTS OF HYBRID CLIMBING ROSES.—A recent part of the *Journal de la Société Nationale d'Horticulture de France* contains a paper by M. G. TRUFFAUT on the food requirements of hybrid climbing Roses. The author chose for his various experiments the sturdy and well-known Rose Madame Ulrich Brunner, and with the assistance of M. COCHET-COCHET and other growers was able to work on a large scale. The results obtained by the various food-constituents are summarised as follows:—The mixture of nitrates and phosphoric acid produced very fine growth, extra large flowers, early, and well coloured. Complete manures poor in potash yielded excellent results, even in soils rich in nitrogen and in phosphoric acid. Roses should be grown in clayey or in clayey-siliceous soils, not over rich in humus. I advise, says M. TRUFFAUT, for manuring Roses in the open ground in autumn, a little cow manure, and in spring to spread on each square metre (rather over 3 feet) 50 grammes of precipitated bone phosphate, 30 grammes of burnt horn, 10 grammes of dried meat, 10 grammes of dried blood (1 gramme = 15.4324 grains). The whole to be forked in. Then, after June 15, the plants should be watered with a solution of 1 gramme per litre (1 litre = 35.2154 oz.) of the following mixture: 50 per cent. phosphate of ammonia, and 50 per cent. nitrate of ammonia; this gives 23 per cent. of nitrogen and 22 per cent. of phosphoric acid. By following these directions, by appropriate pruning, and leaving a moderate number of flowering shoots, bloom will be maintained until November, the flowers being large and fragrant, the stems firm and branching, the foliage dark green and shining, thick, and resisting rust and mildew.

THE FOREST FLORA OF NEW SOUTH WALES.—Mr. J. H. MAIDEN has issued part 2 of Vol. III. of his publication (part XXII. of the complete work), and it contains descriptions and plates of the Hill Flindersia (*F. collina*), Broad-leaved Messmate *Eucalyptus obliqua*, and Cedar Wattle (*Acacia lata*). Vol. III., part 3 (or part XXIII.), contains *Dysoxylon Fraserianum*, *Eucalyptus vitrea*, and *Acacia decurrens*.

CHRYSANTHEMUM SPORTS.—No definite conclusion has been arrived at as to the cause of these productions, but every addition to our knowledge brings us nearer to the goal. On this account we call attention to a statement by M. CLEMENT in *Le Chrysanthème*, to the effect that, in nine cases out of ten, the change is from light colouring to a darker shade. That yellow should be prominent in these sports is only what might have been expected from the ancestry of these plants. A yellow Chrysanthemum is said rarely to produce a white flower, but a white variety may show yellow flowers; a red variety will throw maroon coloured blooms, a rose coloured form will sport into a salmon coloured one.

WINTER-FLOWERING CARNATIONS.—Under the name of Anglo-American Carnations Mr. LAWRENCE COOK gives, in the *Revue de l'Horticulture Belge*, a valuable article on these plants, summarising their history and methods of cultivation, and supplying a list of the more remarkable varieties. The "Malmaison" varieties are also included in the article which is copiously illustrated, though unfortunately process blocks are not to be relied on to reproduce the colours correctly.

THE QUARTERLY JOURNAL OF FORESTRY, a newly-established periodical, "supplies a want" in so efficient a manner as to promise great results in the future. It is edited by Prof. FISHER, of Oxford. The number before us contains, among other articles, one on the Osier bed in the Thames near Syon House, a plantation familiar to many visitors to Kew. The formation of an arboretum near Oxford will be watched with much interest. So far as plants are concerned, the nucleus is furnished by the collection shown a few years since by the late Hon. MARK ROLLE, at the Royal Agricultural Society's show, Park Royal, and noticed by us at the time. Mr. ELWES has an instructive paper on the effects of spring and autumn-frost in the year 1905-1906, and there are various other papers of great interest to foresters of which we are only able to indicate the existence. No one can know better than ourselves how difficult it is to avoid misprints. We shall therefore, we hope, not be thought hypercritical if we point out that the Japanese Larch is *Larix leptolepis*—not "*Leptolepis*"—as it is more than once printed in the journal. The names of the Japanese Spruces *Picea Hondoensis*, *Ajanensis* and *Alcockiana* are also mixed up. The publication is a welcome sign of the increasing attention that is now being paid to our woodlands, and will, we trust, do something to show that trees are of more value than rabbits, and, in the end, more profitable even than big game-bags.

LIFE AND FLOWERS.—By MAURICE MAETERLINCK. Translated by ALEXANDER FEIXEIRA DE MATTOS. (London: GEORGE ALLEN, 156, Charing Cross Road). In M. MAETERLINCK's book we must not expect a treatise on scientific botany, nor instructions upon gardening. The author is a thinker and an enthusiast, and it is in writing of the things, visible and invisible, that make up his "life" that he alludes to flowers. For plants he claims that "none is wholly devoid of wisdom and ingenuity. All exert themselves to accomplish their work, all have the magnificent ambition to overrun and conquer the surface of the globe by endlessly multiplying that form of existence which they represent." In fact he credits plants with what we know as intelligence, with sense as well as sensibility, and with a soul represented by their perfume. It will be seen that the language used is ambitious, apparently the translator has faithfully rendered it, and the result is a chatty volume on various abstract and other matters. If we cannot agree with all M. MAETERLINCK's opinions, it will interest us to consider them, and not to judge them as if they were offered as undeniable facts concerning concrete substances.

REPRODUCTIVE ORGANS OF THE FIG.—M. LECLERC DU SABLON, writing recently in the *Comptes Rendus*, speaks of the method by which Figs are fertilised. There are, he says, two sorts of female flowers on the Fig. Those with a long style are found in most eatable species, and especially in the Smyrna Figs, which usually contain developed seed. The other flowers, with a short style, are found on what are called Caprifigs, the Figs of which are, generally, not eatable; the ovary of these flowers develops, but, instead of the seed, contains the larva of an insect of the *Blastophagus* genus, which is the agent in the pollinisation of the Fig; these are called gall-flowers. The short length of the style enables the *Blastophagus*, which thrusts its oviduct into the stigma, to deposit its egg in the nucellus of the ovule; this is impossible where the style is long. It may then be said that the short style constitutes a symbiotic relationship between the Fig and the *Blastophagus*. The importance of this dimorphism of female flowers has been proved by observations made by SOLMS-LAUBACH. Now, Figs of the second crop of the Caprifig, those which ripen in autumn sometimes contain seeds, although very few in number. SOLMS-LAUBACH found only 20 seeds in 40 Figs, but the condition of the materials did not enable him to discover if the flowers that had produced these seeds had a long or a short style. Nevertheless, writers who have since studied the question, admit a clear specialisation of the two sorts of flowers; those which have long styles, adapted for the production of seed and incapable of admitting the *Blastophagus*, and the others with short styles adapted for symbiosis with the *Blastophagus*, and considered incapable of producing seed. The study of Caprifigs pursued in the departments of the Gard, of Vaucluse, and of Ardèche, has shown the author that the *Blastophagus* exists normally in that region, which has not previously been recorded. Further, in Figs of the third crop from one of these Caprifigs, that is to say, in Figs that remain during the winter on the tree and ripen in spring, M. LECLERC has observed in the middle of gall-flowers inhabited by the *Blastophagus* numerous achenes containing well-developed seeds, with an embryo and albumen like those of the Smyrna Figs. He has further noted that the flowers that produced these seeds had short styles like the gall-flowers. This observation showed, first, that the Caprifigs can produce seeds, not only in the autumn Figs, but also in the winter Figs, which had not been previously noted. In the second place, the production of seed by the short-styled flowers showed that the specialisation of the two sorts of female flowers is not complete—at least, as regards the short-styled flowers. These are able to produce seed as well as to nourish the *Blastophagus*. The Caprifig cannot therefore be considered, as is often the case, as being the male Fig, whose part it is to produce pollen and to nourish the insect destined to transfer the pollen to a female plant. It is monœcious, with separate male flowers and female flowers normally constituted, and may be taken as the type of a species. The Figs of the first crop, ripening in summer, include male flowers which produce pollen, and female flowers which support the *Blastophagus*; issuing from these Figs, the *Blastophagus*, covered with pollen, enters a Fig of the second or third crop, which normally includes only female flowers, and there may either deposit its eggs in the ovaries, thus ensuring the preservation of its species, or it may pollinate certain flowers, which will produce seed destined to reproduce the Caprifig. But flowers producing seed are of exactly the same constitution as are the gall-flowers.

IRIS IBERICA.—Mr. AMOS PERRY writes as follows from his Hardy Plant Farm, Enfield, Middlesex:—"I showed *Iris iberica* on April 30 at the meeting of the Royal Horticultural Society, and there appears to have been a good deal of doubt about plants flowering in the open air. I have a bed of these in flower now in the open. Many of the *Oncocyclus Iris* grow and do much better when planted in a spot congenial to their requirements, that is hot, dry soil and very stony. *Iris Susiana* I never saw looking better, every root, I think, is going to flower well, and almost every plant of *Iris iberica* will be in flower during the next fortnight or three weeks."

AGRICULTURAL EDUCATION.—The departmental committee, of which Lord REAY is chairman, held meetings on April 30, and May 1 and 2. Representatives of the agricultural department, Cambridge University; Armstrong College, Newcastle-on-Tyne; South Eastern Agricultural College, Wye; Essex County Technical Laboratory (Chelmsford), and the Agricultural College, Holmes Chapel, Cheshire, attended and gave evidence.

BIRMINGHAM PUBLIC PARKS.—The display of bulbous flowers in the Birmingham parks is this season more beautiful than ever. Beds at Cannon Hill Park, now glowing with brilliant colour, each contain no fewer than 3,000 bulbs, whilst here and in the other parks of Birmingham there are scores of flower-beds and borders holding 1,000 bulbs each. At Warley, and also at Lightwoods, a pretty effect has been secured by planting a large number of Daffodils in the grass, and in this connection it may be noted that the efforts of the Baths and Parks Committee to beautify the parks have been greatly aided by the generous gift of 50,000 Narcissi from Mr. R. SYDENHAM. At Cannon Hill Park a great improvement has been effected in the extended rockery by the side of the first pool. Mr. W. H. MORTER, the present superintendent of the City Parks, has greatly developed bulb-cultivation in most of them, and the displays in spring are much appreciated by the public.

INFLUENCE OF THE SCION UPON THE STOCK.—In a recent contribution to the *Journal de la Société Nationale d'Horticulture de France*, M. G. RIVIERE records the results of some experiments made by him in grafting Apples. On a previous occasion, M. RIVIERE had shown that the weight or quantity of sugar in the fruit of the Apple Calville Blanc varied according as it was grafted upon the Paradise stock or on the Doucin Apple. In his later paper he gives the results obtained by grafting Doyenné d'Alençon Pear on the Quince stock and on the Doucin Apple. The new experiments confirm the former ones, showing that the fruits borne by the graft are always plainly influenced by the stock, and, undoubtedly, with special reference to the Pear, that the Quince, among the stocks hitherto studied, exercises the most valuable influence, not only as regards increasing the size of the fruits of our garden varieties, but especially and particularly it furthers the formation of sugar in the pulp. It should be added that Doyenné d'Alençon grafted on the Quince is represented at Versailles by a handsome pyramidal tree, nine years old, while Doyenné d'Alençon, grafted on the Doucin Apple, the vegetation of which is always poor, forms but a poor tree with very short lateral branches. It flowered first in 1906 at the age of 13 years and, always a weak plant, yielded but three Pears. This, clearly, is useless as a stock in a nursery; but it seems desirable to notify this unprecedented (?) instance of longevity in a Pear grafted on an Apple.

THE GENUS EUCALYPTUS.—Mr. J. H. MAIDEN has lately published part VIII. of his handsome *Critical Revision of the Genus Eucalyptus*. This includes the descriptions and illustrations of four species: *Eucalyptus capitellata*, *E. Muellieriana*, *E. macrorrhyncha*, and *E. eugenioides*.

VEGETABLE TERATOLOGY.—Mr. W. C. WORSDELL, of the Jodrell Laboratory, Royal Gardens, Kew, who is preparing a work on the subject of vegetable teratology, would be greatly obliged to any correspondent who could favour him with specimens, drawings, or notes of abnormalities of any kind in the vegetable kingdom.

HYACINTH PRIZES IN 1908 AT ROYAL HORTICULTURAL SOCIETY'S MEETING.—The Royal Dutch Bulb Growers' Society at Haarlem have offered to present, and the Royal Hor-

PHOTOGRAPHIC APPARATUS.—Herr JOHANN RIEDL, Goerlitz, Schlesien, forwards a catalogue of the cameras and photographic accessories which are a speciality of his firm. His descriptions and lists are useful because published in four languages, German, English, French and Italian, in parallel columns.

ETHERISATION OF STRAWBERRIES.—The subject of the treatment of Strawberries by etherisation is mentioned by M. COUDRY in the *Journal de la Société Nationale d'Horticulture de France*. The writer records that: "M. BULTEL, Head Gardener at the Chateau d'Armainvilliers, Grevy (Seine et Marne), in January, 1906, staged three lots of the Strawberry Vicomtesse Hericart de Thury, raised under different treatments, and showing that Strawberries previously subjected to etherisation not only flowered and fruited

FIG. 124.—ODONTOGLOSSUM PRINCE EDWARD OF WALES: FLOWER WHITE WITH PURPLE MARKINGS. (See p. 303.)

icultural Society has accepted, the undermentioned prizes for forced Hyacinths to be competed for at the Royal Horticultural Society's Show at Vincent Square on Tuesday, March 31, 1908. Each bulb must be in a separate pot (size optional), and all must have been forced entirely in Great Britain or Ireland. No exhibit may contain more than two specimens of any one variety; and no exhibitor may exhibit in more than one class. *Division I.—For amateurs and gentlemen's gardeners.*—Class 3.—18 Hyacinths, 1st prize, £8 8s.; 2nd, £4 4s. Class 4.—12 Hyacinths, 1st prize, £6 6s.; 2nd, £3 3s. Class 5.—6 Hyacinths, 1st prize, £4 4s.; 2nd, £2 2s. *Division II.—For nurserymen.*—Class 6.—24 Hyacinths, 1st prize, £8 8s.; 2nd, £4 4s. Class 7.—18 Hyacinths, 1st prize, £6 6s.; 2nd, £3 3s. Class 8.—12 Hyacinths, 1st prize, £4 4s.; 2nd, £2 2s. W. Wilks, Secretary.

earlier, but also bore a larger yield of fruit than others." The excellent results obtained everywhere by etherisation encourage many persons to apply the treatment, which is becoming general, and is likely to prove of great value, provided that the ether is not used for plants beginning their season of growth. M. BULTEL raises an interesting question by enquiring if plants etherised that they may produce earlier fruit give as satisfactory results as those obtained when earlier flowering is desired, as with Lilacs and other subjects. M. BULTEL answers in the affirmative. He bases his opinion on experiments he has made with Strawberries and Cherries, and which he proposes to continue with other plants. Another experiment made by M. BULTEL on the Strawberry Royal Sovereign proved that its early maturity and increased yield were wholly due to etherisation.

DESTRUCTION OF SLUGS AND SNAILS.—A paragraph in the April number of the *Journal of the Board of Agriculture* mentions several ways in which slugs and snails may be destroyed. A quotation from a Mexican agricultural circular recommends the obvious but tedious remedy of hand-picking, and also says that: "Pieces of board smeared with fat on the underside are laid down in infested places, with room beneath for the snails to collect. Cabbage leaves with rancid butter on one side, Melon rinds, and the leaves of the common Acacia are useful in attracting snails. A useful trap for slugs may be made of an earthen flower-pot provided with a cover and having a row of holes round the middle. These pots are sunk in

and stretched round the border. Bands of cloth soaked in this solution and fastened round the tree stems prevent the ascent of slugs and snails, while a solution of iron sulphate 25 per cent. to 50 per cent. applied in a ring 4 inches wide round the trunk of the tree is also said to stop their passage. The pests may be killed in weeds, hedges, &c., by spraying with a 1 per cent. solution of copper sulphate, or a 1 per cent. solution of common salt."

VEGETABLE RESOURCES OF THE TRANSVAAL.—Mr. J. BURTT DAVY, F.L.S., Government Botanist in the Transvaal, is expected to deliver a lecture on the Vegetable Resources of that colony before the Scientific Committee of the R.H.S. at Vincent Square, Westminster, on Tuesday next, at 4 p.m.

Porter and R. C. Gaut.—*The Animals' Friend*. April. —*Proceedings of the Western New York Horticultural Society*. January, 1907. This is a vigorous society, and the editor of the proceedings, Mr. John Hall, forwards an encouraging account of its work. This has now been carried on for 52 years, and deals with every branch of horticulture.—*Journal de la Société d'horticulture du Japon*. March. An illustrated journal, printed in Japanese, and issued at Tokio.—From the New Zealand Department of Agriculture. *Agriculture in New Zealand*, Hon. Robert McNab, Minister for Agriculture; and *Report of the Divisions of Biology and Horticulture and Publications*, T. W. Kirk. Includes papers on the fungoid and insect pests investigated during the year, and on fruit imports, exports, cultivation, &c.—*The Sydney Mail*. This well-known publication speaks of criminal waste of timber owing to the construction of a railway through the Dorrigo country, wholesale and needless destruction having, it is said, been wrought. This is to be regretted in any district, and it is hoped that the aid of the Department of Forestry will be involved.—*Interim Report of the Experimental Farms, Ottawa*. December to March 31, 1906. Spottiswoode & Co., New Street Square. E.C.

TWO NEW ORCHIDS.

ODONTOGLOSSUM × PRINCE EDWARD OF WALES.

OUR illustration (fig. 124) represents a flower of the beautiful *Odontoglossum* obtained by Messrs. Sander & Sons, St. Albans, from a cross between *O. Rolfeæ* (*Pescatorei* × *Harryanum*) and *O. crispum* (*Harryanum* × *Harryanum*), and for which a First-Class Certificate was awarded at the Royal Horticultural Society on April 30 last. It is a very fine production, showing in a remarkable degree the advantages of inter-crossing good hybrids, for in the present variety it is easy to trace the features of all the species used in its production. The plant is a strong grower, and the flowers are white, beautifully marked with purple with a violet shade on some of the markings.

BRASSO-LÆLIO-CATTLEYA FOWLERI. (CATTLEYA SCHRODERÆ AURANTIACA × BRASSO-LÆLIA MRS. M. GRATRIX.)

"A PRETTY flower, and quite a new departure in colour" was the general opinion of the Orchid Committee of the Royal Horticultural Society on April 30, when it awarded a First-Class Certificate to this charming hybrid shown by J. Gurney Fowler, Esq., Glebelands, South Woodford (gr. Mr. J. Davis). *Brasso-Lælia* Mrs. M. Gratrix is derived from *Lælia cinnabarina* and *Brassavola Digbyana*, and through it the underlying of the yellow tint in *B.-L.-C. Fowleri* and the crimping and slight fringing of the lip may be traced, the influence of *Cattleya Schroderæ* giving form and substance. The blending of the colours and their soft tone are indescribably beautiful. The ground colour is yellow, but the whole surface is tinged and delicately veined with salmon-rose. The large disc of the lip is buttercup-yellow, with a broad margin of salmon-rose.

FIG. 125.—BRASSO-LÆLIO-CATTLEYA FOWLERI: COLOUR OF FLOWER, YELLOW TINGED AND VEINED WITH SALMON-ROSE.

the ground so that the holes come about at the surface. The inside of the pot is smeared with beer, a small amount of which is put into a dish at the bottom. Another useful trap is a cone of galvanised iron bored with many holes, sunk in the ground and baited with pieces of Potato, Carrot, or Apple. When snails and slugs have been trapped they may be killed by being left for five hours in a 5 per cent. solution of copper sulphate in water, or a 2 per cent. solution of lime in water. The pests may be kept away from a garden by a rope of grass or fibre soaked in a 10 per cent. solution of copper sulphate

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

TULIPS IN THE VICTORIA PARK, SWANSEA.—During a recent visit to Swansea, I was invited to inspect the Tulips in the Victoria Park of that town. There are some 45 flower-beds, most of which are cut out in the turf, and they are now filled with these beautiful bulbous flowers. The large centre bed contains some 900 bulbs, the variety being Thomas Moore, a very distinct variety of an orange-scarlet shade. Mr. Bliss, the superintendent, informs me that this variety is much admired by visitors. Joost Van Vondel was also very fine, in its large pure-white flowers. Four beds were devoted to Proserpine, a rich, dark rose-coloured variety, having splendid and large flowers. The old favourite, Cottage Maid, formed some of the most effective beds in the group. The colouring is rose-pink shaded with white. Ophir d'Or, a pure golden-yellow flower, large and fine of shape, is the best yellow Tulip known to me for bedding purposes. It is very sturdy of habit. Another variety of merit I noticed was Dusart, with flowers a dark crimson. Four beds were planted with the rosy-pink Van Berchem, and other varieties noticed were Artus, Canary Bird, Empress of India, Grace Darling, and Montessoro. I was impressed greatly with the evenness of the whole, and the good blending of the colours. Since Mr. Bliss was appointed, a little more than four years ago, as parks superintendent, he has made much improvement, and his work is fully appreciated. *R. Milner, Margam Gardens.*

A GREEN PRIMROSE.—I send specimens of a green-flowered Primrose recently discovered by Lady Grisell Hamilton in the Wilderness at Tynningham. On examination it was found that what appeared to be a small clump was really three plants, apparently two or three years from seeds. Green Primroses were common two to three hundred years ago, and probably much earlier, for Spenser mentions the flower as associated with Violets and other flowers in a chapter, and all the early herbalists describe it, as well as green Cowslips, both single and double. Parkinson gives the best description, but unfortunately he does not figure it. It was "very near the same yellowish green colour that the huske is of," which agrees with the flower in question. *R. P. Brotherton.*

FRUITS OF ROYAL SOVEREIGN STRAWBERRY AT THE HORTICULTURAL HALL.—Many visitors to the last meeting of the R.H.S. would doubtless ask themselves if there is merit in producing Strawberries of such enormous size. The variety has nothing to recommend it on the score of flavour, and the size and weight of the fruits shown—2 oz. each—seemed scarcely desirable points in a Strawberry. I opine we have several varieties (omitting British Queen) of fine flavour, good bearing qualities, and handsome in shape, that greatly excel Royal Sovereign in every quality but size. Varieties comparatively modern are Doctor Hogg, Latest of All, Vicomtesse Héricart de Thury, President, La Grosse Sucrée, and of old ones, Auguste Nicaise, Carolina Superba, Duke of Edinburgh, Filbert Pine, James Veitch, and Lucas. It amounts almost to a heresy to mention nowadays the varieties Keen's Seedling, Loxford Hall, Early Prolific, "Paxtons," or "Napiers." *F. M.*

WEATHER IN DEVONSHIRE.—April has been an exceptionally wet month, and we have registered 5.22 inches of rain. The rainfall in the previous three months was 1.19, 1.39, and .66 respectively. Several heavy showers of hail fell on the last day of April. Trees generally give signs of a good fruit year in this neighbourhood. *Fred Leach, The Avenue Gardens, Brampford Speke, Exeter.*

EUPHORBIA (POINSETTIA) PULCHERRIMA.—I have succeeded in obtaining fertile seeds from this species, and have now raised plants from these seeds. Is this an unusual occurrence? I may say the plants were grown in cool frames, and they flowered in an ordinary plant stove. As the seed was ripening, small bracts developed at the base of the seed pods, and the plants retained most of their foliage. *E. Robinson, Swinfen Hall Gardens, Lichfield.*

TO PRUNE OR NOT TO PRUNE.—I was surprised at Mr. Udale's report on page 249, for when I called and saw his trees a few years ago I left under the impression that he was all but an out-and-out non-pruner, which impression was confirmed more or less by his little book which he sent me later, but which I have not at hand at present. I do not consider his experiments either scientific or conclusive, and certainly not exact or complete enough to set against the Woburn tests. Such expressions as "carefully," "badly," or "roughly" pruned, &c., convey no meaning, and his hypothesis that, under equal conditions, the fruit of pruned trees must be larger and of better quality, as I apprehend him, is one that I would be surprised to see any authority on vegetable physiology of repute put his name to. I thought it was held by every experienced fruit-grower that the size and quality of an Apple, for example, depended upon the number of Apples the tree or branch was allowed to carry, proper nourishment at the root, and the proportion of healthy foliage maintained, and I entirely fail to see why all these conditions cannot be secured on an unpruned tree as well as on a pruned one. I never had any difficulty whatever in the matter from the Gooseberry up to the Vine or Peach. I was in Mr. Udale's locality the week after his article appeared, and I saw many gardens and orchards, both new and old, grass orchards and fallow ones, and I was struck by the fact that I did not come across one example of Mr. Udale's practice either in Plums or Apples. If you want size and quality on an unpruned tree it is a matter of thinning. The principle involved is the same. All the other conditions being equal, will Mr. Udale explain how the pruned tree alters the size and quality of the fruit? If he has got the facts, he ought to be able to provide a theory to fit. *J. Simpson, Studfield.*

—Arising out of the experiments conducted at Woburn, the results of which were recently published by the Duke of Bedford and Mr. Spencer Pickering in the Bedford Experimental Fruit Farm's Report, a discussion on the subject of pruning or non-pruning of fruit trees, though naturally one-sided, took place at the meeting of the Fruit Committee of the Royal Horticultural Society on April 30, at which some 25 to 30 members were present. The chairman, Mr. G. Bunyard, practically voiced the views of the members when he ridiculed the assumption that fruit-tree pruning was wrong practice. No member supported the Bedford theories. Such discussions may well employ so important a body of experts as that of the Fruit Committee, especially when they find little before them in the way of exhibits. *Member.*

DETERIORATION IN STRAWBERRIES.—I quite agree with the remarks on p. 268 upon the necessity for early planting, and this applies equally to Strawberries in gardens as in fields. I have had no experience in the field culture of Strawberries, but the failures to which your correspondent refers are likewise apparent in many gardens. Careful selection of runners and early planting is of little avail unless careful attention is given to the plants from the runner stage to the time of their fruiting. A system of culture by which I have obtained 1½ lb. of fine fruit per square yard is as follows:—Plants for furnishing runners are planted in rows about the end of September in ground that has not carried a similar crop for three or four years past. The flowers are pinched out directly they appear, and any plants not showing flowers are discarded. Layering is commenced in 4-inch pots as soon as the runners develop, and about four are allowed to each plant. When the young stools are large enough, they are severed from the parent and stood on the shady side of a wall or glasshouse. The ground intended for their permanent planting should be well trenched the previous autumn or early spring, and be planted with early Peas or with early Potatoes—preferably the former. When trenching, plenty of potting shed refuse and good rotten manure should be incorporated with the soil, and a dressing of freshly-slaked lime applied at the finish. The early crop of Peas should be harvested by the end of July, when a dressing of rotten manure, loam and lime should be dug in one spit deep. Plant the Strawberries about the middle of August in lines 2 feet apart, allowing 20 inches between

the plants in the rows, keeping the crowns rather low in planting. If the weather is very dry at the time of planting, give copious waterings until the plants are actively rooting. The Dutch hoe should be worked in the rows at least once every week. About the end of October a layer of manure should be placed about the plants and allowed to remain through the winter, and raked off again about the middle of March following, when a good sprinkling of lime should be lightly forked in the ground. The Dutch hoe should be kept going between the plants, and all runners must be pinched off until nets are put on later. About the time when the plants are in full bloom, a good soak of liquid manure should be given. After the plants have finished flowering, a layer of bracken-Fern should be placed about them, care being taken to work it well around each plant. If any slugs remain after the lime and hoeing, the rough Fern will deter them so that very few slug-eaten fruits will be found. For supporting the netting, stout stakes or posts 4 feet in length are driven into the ground at 6 yards apart, and from these galvanised wire is stretched to carry the nets. This allows about 3 feet 6 inches head room, and enables the fruits to be gathered without removing the nets. If, after the first gathering (about June 17), the weather is very dry, the hose should be freely applied, for at this stage much water is needed, and with the use of bracken for litter no fear from mildew need be entertained. The plants should only be cropped for two years: the second year they are about two weeks later in fruiting, but, by making a new bed each year, early and later crops are obtained. The varieties grown here are: Royal Sovereign, Laxton's Leader, Fillbasket, and Sir Joseph Paxton. An exchange of runners with some grower at a distance every three or four years is very desirable. *George Ferrington, Penbedw Garden, Nannerc, North Wales.*

LEAD ARSENATE AS A SPRAY.—Referring to Mr. Spencer Pickering's note (p. 271) on arsenate of lead as a destroyer of leaf-eating insects, your readers may not all be aware that there is always a considerable risk to foliage in using a home-made mixture of sodium arsenate and acetate of lead unless it is very carefully prepared. There is always the possibility of free sodium arsenate remaining unabsorbed by the acetate, and sodium arsenate will destroy almost any herbaceous growth; it is indeed a very effective weed killer. All risk of that kind is avoided by using a preparation, such as Swift's arsenate of lead (referred to on p. 271), which is so prepared as to contain an excess of acetate (which is quite harmless), and, in addition, a substance which makes it adhere to the leaves. I have excellent reports of experiments made last year in Ireland with Swift's arsenate, and it is now being generally asked for here. *D. M. Watson, Ph. Chemist.*

CARBONIC ACID GAS.—In reference to the very interesting article on carbonic acid gas by Mr. C. T. Druery, on p. 277 of the issue of May 4, it may be mentioned that at the Rothamsted Laboratory we have a bottle holding about 200 ounces of soil taken from the top 9 inches of one of the experimental fields in October, 1874. During the sampling a waft of wind must have conveyed a spore of an Asplenium Fern to the soil, because there were no Ferns growing in this field, but there were Ferns in a private garden some distance away. A short time after the soil had been placed in the bottle and tightly corked it was observed that a Fern had made its appearance; the cork was then hermetically sealed with a thick coating of wax. From that time to the present, a period of 33 years, the Fern has continued to grow, and quite fills up the bottle. The roots have permeated through the whole soil. The Fern partially dies down occasionally, and then springs up again with great vigour. We must repeat the question of Mr. Druery—"How is it done?" Experiments in vegetation show that plant growth and the metastasis in the tissues necessarily connected with it only take place so long as oxygen can penetrate from without into the plant. In an atmosphere devoid of oxygen no growth can take place, and if the plant remains for any length of time in such an atmosphere it perishes. The formation and exhalation of carbonic acid gas, that is to say, the carbon resulting from the decomposition of the organic

compounds in the soil contained in the bottle, may always be observed in the warmer weather by the production of water on the inner surface of the bottle, at the expense of the organic substance of the soil, in consequence of the process of respiration. The whole life of the plant consists in complicated movements of the molecules and atoms, and the forces necessary for these movements are set free by respiration. The oxygen, while decomposing parts of the assimilated substance, sets up important chemical changes in the remaining portion, which, on their part, give rise to diffusion-currents, and these bring into contact substances which again act chemically on one another. There is thus sufficient oxygen and moisture in this bottle of soil to produce the whole cycle of plant-life for a continuous succession of 33 years, and there appears no reason why this condition of things should not go on for another similar period. *J. J. Willis, Harpenden.*

YOUNG GARDENERS' LITERARY EFFORTS.—

On several occasions I have been invited to act as reader and adjudicator of essays written by young gardeners in competition for prizes offered by mutual improvement societies, and as a result I have to express regret that in so few cases do these essays merit praise as literary compositions. How far my experience may be that of others who undertake similar duties I cannot say, but that I have found such defects lead to the impression that young men too frequently enter the gardening profession somewhat indifferently equipped, educationally, and once in the profession do not seem to improve themselves when the need for doing so becomes apparent. Spelling is in many cases very weak, punctuation is specially so. Sentences are not individualised, but run one into the other without stops or commencing capitals. The general composition of the papers, too, is faulty, writers failing to express themselves clearly and lucidly. In many cases the omission of a useful word or two leads to the impression that the task of writing is rather an irksome one, and is therefore treated negligently. In connection with the responsible work in relation to the registration of efficient gardeners by the British Gardeners' Association, something useful might well be done in inviting each candidate for registration to write a short letter or essay on some gardening subject to test literary merit. Of course, a gardener may be a very capable one, but still be an indifferent hand at composition. At the same time it is obvious to all, old or young, that in making applications for situations, or writing ordinary business letters to employers, or to nurserymen, that any such communication if clearly, lucidly and excellently written, must convey a much better impression of the writer's capacity than would an indifferent effort. I should like to see an examination in literary composition by young gardeners below the position of foremen undertaken by gardeners' societies all over the kingdom. Some impulse might then be given to literary improvement. *A. D.*

A WELL-ARRANGED PINETUM.—Canterbury may, at no very distant date, be famous for its collection of Coniferous trees, for on the high ground above the town in a charming situation, and where the soil is most accommodating, Mr. Neville Cooper, of Vernon Heath, the son of the famous animal-painter, has devoted a large area of ground to the growth of his favourite trees. Originally the land was under coppice wood, but this has been cleared away, except a shelter band on the exposed sides, and planted with a very representative collection of Conifers, home and Continental nurseries having been ransacked for the rarest species and varieties. Naturally many of these were of small growth when obtained, and hardly fitted for permanent planting, so Mr. Cooper conceived the excellent idea of having a private nursery in Scotland, with the result that at Crieff one was established where the pure air and exposed situation render the majority of Conifers peculiarly suitable for their permanent situation in the garden of England. Of Abies alone there is an extensive collection of some ninety species and varieties; while the Cypressess exceed half a hundred, and of Cedars no fewer than sixteen kinds are under cultivation. Mr. Cooper is an enthusiastic cultivator, and one of the pleasantest days I have spent for a long time was amongst his Conifers at Canterbury. *A. D. Webster.*

SOCIETIES.

ROYAL HORTICULTURAL

Scientific Committee.

APRIL 30TH.—*Present:* Dr. M. T. Masters, F.R.S. (in the chair), Messrs. G. Massee, E. M. Holmes, W. C. Worsdell, G. Gordon, A. Worsley, E. A. Bowles, J. T. Bennett-Poë, A. W. Sutton, G. S. Saunders, J. Douglas, R. A. Rolfe, Ed. Mawley, and F. J. Chittenden (hon. sec.).

African Crinums.—Mr. WORSLEY reported that the Crinums shown at the last meeting by Mr. ELWES were *C. giganteum* and *C. Macowani*. Some years since Messrs. BULL sent out a pink variety of the former as *C. nobile*, so that *C. nobile* var. *album* would, under this nomenclature, represent the type. The finest varieties of this species have widely-expanded flowers (such as var. *Rattrayi*, &c.). They are all fragrant, and some of them (as in the case of the form now shown by Mr. ELWES) are very fragrant. On this account the name "*vanilodorum*" was given to a form of this species. *C. Macowani* has been the subject of much confusion. The plant figured under this name in *Bot. Mag.*, tab. 6381, is *C. Moorei*, *C. Macowani* is the southernmost representative of a widely-distributed species that spreads northwards at least as far as the equator, and passes by indiscernible gradations into forms of *C. latifolium*. The form shown by Mr. ELWES is practically sessile, and in this respect is not identical with the forms originally described by Mr. BAKER under *C. Macowani* (*Handbook of Amaryllideae*, p. 94).

Fungus on Retinospora.—Mr. SAUNDERS showed a specimen of *Retinospora* (immature form of *Juniperus chinensis*) attacked by the fungus *Gymnosporangium* sp., which forms jelly-like masses on the shoots.

Auricula with petaloid stamens.—Mr. J. DOUGLAS showed an Auricula in which the stamens of most of the flowers had become petaloid; in some they were well developed, in others quite minute.

Ceropegia Woodii.—Mr. WORSLEY showed seeds of this plant, which, like so many of the family to which it belongs, is provided with a parachute arrangement for the distribution of the seed. Mr. WORSLEY said that the hairs appeared to be sticky. He also showed a shoot which had been hanging down quite freely, bearing little tuberous growths upon it. The formation of these small tubers had been attributed to contact of trailing shoots with damp earth, but that could not have been the exciting cause in this case. He thought that possibly irritation by insects might have excited their formation. Not all shoots bear these tubers when hanging freely down.

Genetics.—Mr. WORSLEY thought that the committee should by some means or other be kept informed of the progress made in the investigation in progress into the laws of inheritance, and it was left to the secretary to ascertain from members what could be done in this direction.

Colouration of Hawthorn leaves.—Mr. HOLMES showed leaves of Hawthorn bearing crimson patches, and remarked that these coloured spots followed as the result of injury by insects, in the case in point apparently by aphides. These colours so produced are not, it has recently been shown, due to anthocyanin, but to bodies allied to the phenols. Mr. HOLMES stated that "M. ARMAND GAUTIER has shown (*Comptes Rendus*, CXIV., p. 624) that an injury done to the petiole of a vine leaf causes the formation in the leaf, of a red colouring matter, similar to that produced in autumn, and he now states (*Comptes Rendus*, CXLIII., p. 490) that the colouring matter produced by injury or not, as previously supposed concerning anthocyanin or erythrophyll, a uniform colouring matter derived from chlorophyll, from which it differs in containing neither nitrogen nor phosphorus, but belongs to the coloured phenol acids, is crystallisable, and of the nature of tannin. These pigments vary with each kind of plant, and those of fruits are not identical with those of leaves, although related to them. According to M. MIRANDE, the lesions produced by various fungi on leaves, e.g., *Ramularia*, *Cercospora*, *Septoria*, *Ovularia*, *Coryneum*, and *Gloeosporium* have the same effect in producing the red

colouring matter." The exciting cause in the case of the Hawthorn leaves shown appears to have been the attack of aphides.

Geaster fornicatus.—Mr. MAWLEY showed an excellent specimen of this curious fungus found growing by the roadside at Berkhamsted.

Contortion in Carnation.—Dr. MASTERS showed a specimen of Carnation having a curiously-contorted stem, similar in appearance to the fasciated and contorted stems often seen in the Teasel. It was referred to Mr. Worsdell, who will report upon it at the next meeting.

Pelargonium sport.—Dr. MASTERS also showed specimens of flowers taken from a show Pelargonium which normally produced irregular single flowers, with purple blotches upon the upper petals. A lateral branch from this sported, so that it bore regular flowers and had the stamens replaced by petals. This sport was reproduced by cuttings.

NATIONAL AURICULA AND PRIMULA (MIDLAND SECTION).

MAY 1.—The eighth annual exhibition in connection with the above society was held at the Botanical Gardens, Edgbaston, Birmingham, on this date, and was the most successful show ever held by the society. The quality of the exhibits was excellent, the weather fine, and the attendance large. Northern growers were represented by Mr. TOM LORD, of Todmorden, and Mr. W. M. SHIPMAN, of Altrincham. The grey-edged Auricula Richard Headley was shown in splendid condition, and Mr. TOM LORD won the premier prize for the best show Auricula in the exhibition with a superb plant of this variety. Mr. LORD also secured the principal honours in the classes for show Auriculas, but he was not so successful in the classes for Alpines, the Birmingham growers being particularly strong with these. The premier Alpine Auricula was a beautiful flower with a golden centre named Mrs. Danks. It was raised by Mr. Richard Holding, several years ago, and was shown on this occasion by Mr. CHARLES WINN. There were several notable honorary exhibits, including a fine group of Polyanthuses and Primroses shown by Messrs. STORRIE & STORRIE, of Dundee (Silver Medal); a similar exhibit of Polyanthuses and Primroses displayed by Mr. S. MORTIMER, Farnham, Surrey (Silver Medal); a showy exhibit of Zonal Pelargoniums from Messrs. BAKER'S, Wolverhampton (Silver Medal); and an interesting collection of Cacti and succulent plants shown by Mr. W. C. G. LUDFORD, Four Oaks, Sutton Coldfield (Silver Medal).

The show was opened by Mrs. George Cadbury, who gave an address on the Auricula and its suitability for culture, especially in towns, by working men. The Botanical Gardens were in their full spring beauty, and added much to the enjoyment of the numerous visitors.

SHOW AURICULAS.

The principal class was that for eight dissimilar varieties, and, as stated, Mr. LORD secured the leading position with a fine display, his examples being Ruby, Richard Headley, Mrs. Dodwell, Shirley Hibberd, Acme, George Lightbody, Abram Barker, and Mrs. Potts. 2nd, W. M. SHIPMAN, Altrincham, with Gerald, Abram Barker, Richard Headley, Shirley Hibberd, Mrs. Potts, Miss Ethel Dinham, and Acme. 3rd, W. C. G. LUDFORD, Four Oaks, Sutton Coldfield.

Six show Auriculas, dissimilar.—The premier collection was staged by Mr. LORD, and the same award was gained by Mr. W. SHIPMAN as in the preceding class, but Mr. CHAS. WINN, Selly Park, reversed positions with Mr. LUDFORD in the 3rd and 4th places. Mr. LORD showed Richard Headley, George Lightbody, Mrs. Henwood, Mrs. Potts, Abram Barker, and Acme. Mr. SHIPMAN had Acme, George Lightbody, Shirley Hibberd, Richard Headley, Abram Barker, and Gerald.

Four show Auriculas, dissimilar.—Mr. S. T. HEALEY, Leicester, was awarded the 1st prize for good examples of James Hannaford, Richard Headley, Gladiator, and Favourite. 2nd, Mr. J. COLLIER, Junr., Ludlow, with Heatherbell, Beauty, Abram Barker, and Mrs. Potts.

Mr. HEALEY also won in the class for two show Auriculas, his examples being Henry Wilson and Mrs. Phillips. Mr. A. LAWTON, Aston, secured the 2nd prize in this class.

Two Show Auriculas.—This is a special class provided for cultivators who have not previously exhibited. The 1st prize was awarded to Mr. A. E. CLUTTERBUCK, Sutton Coldfield, his examples being Ruby and Mrs. Potts. 2nd, Mr. E. SAUNDERS, with Ruby and Miss Barnett. Mr. CLUTTERBUCK also won in the similar class for two Alpine Auriculas.

SINGLE PLANTS.

Green edge.—Mr. LORD secured both the 1st and the 2nd prizes in this class with Shirley Hibberd and Abram Barker respectively.

Grey edge.—Mr. LORD again won, having the best example in a plant of Richard Headley, and the 2nd best in another plant of this variety.

ALPINE AURICULAS

Eight Alpine Auriculas, dissimilar.—The 1st prize in this important class was gained by Mr. W. C. G. LUDFORD. He showed Argus, Mrs. M. Smith, J. F. Kew, Duke of York, Thetis, Firefly, Teviotdale, and George Cadbury. 2nd, Mr. C. WINN, with Miss Knox Taylor, Firefly, Teviotdale, Rosy Morn, Thetis, Gipsy Girl, Argus, and Duke of York.

Six Alpine Auriculas, dissimilar.—Mr. LUDFORD and Mr. WINN reversed positions in this class. The premier flowers were Mrs. Danks, Enteric, Thetis, Valiant, Argus, J. F. Kew. Mr. LUDFORD had Firefly, Rosy Morn, Thetis, Argus, &c.

Four Alpine Auriculas, dissimilar.—1st, Mr. RICHARD HOLDING, with Prudence, Mrs. Danks, Argus, and Duke of York. 2nd, Mr. A. WADLEY, with Argus, Duke of York, Thetis, and Mrs. Turner.

LINNEAN SOCIETY.

MAY 2.—At a general meeting held on the above date, the general secretary exhibited, on behalf of the owner, two portraits of John Fraser, F.L.S., by John Hoppner and Sir George Raeburn; the latter, he pointed out, was the unacknowledged source of the lithographed portrait in Hooker's *Companion to the Botanical Magazine*, Vol. II. (1836), p. 300. The following note accompanied the exhibit:—

"John Fraser (1750.1811) was born at Tomnacloch, Inverness-shire in 1750, and apparently came to London in 1770, when he married and settled as a hosier and draper at Paradise Row, Chelsea. Having acquired a taste for plants from visiting the Botanical Garden, Chelsea, then under the care of Forsyth, he sailed for Newfoundland in 1780 in search of new species, returning the same year. In 1784 he embarked for Charleston, whence he returned in 1785,

FIG. 126.—FAMOUS GLOBOSE YEW AT CHERKLEY COURT, THE LATE RESIDENCE OF MR. ABRAHAM DIXON, WHO DIED ON APRIL 30, AGED 92 YEARS.

White edge.—Acme, shown by Mr. LORD, was placed 1st; and the same variety, shown by Mr. PARTON was awarded the 2nd prize.

Sels.—Mr. LORD was again to the fore, taking both the 1st and the 2nd prizes with Ruby and Mrs. Potts respectively.

Three Show Auriculas.—This class was open to local growers only, and resulted in Mr. W. C. G. LUDFORD winning with Abbé Liszt, Gerald, and Shirley Hibberd. 2nd, Mr. CHARLES WINN, with George Rudd, Mrs. Phillips, and Mrs. Sheppard. 3rd, Mr. RICHARD HOLDING.

The premier show Auricula in the exhibition was a very fine specimen of Richard Headley, shown by Mr. T. LORD.

The best single plant of an Alpine Auricula with a golden centre was Golden Acme, shown by Mr. RICHARD HOLDING. Mr. CHARLES WINN won the 2nd prize with the same variety; and the best with a light centre was Mr. W. H. PARTON's Thetis.

The premier Alpine Auricula in the show was the variety Mrs. Danks, shown by Mr. CHARLES WINN. The best six fancy Auriculas were shown by Mr. CHARLES WINN.

There were also a number of classes for seedlings, in which the principal exhibitors and winners were:—Messrs. Richard Holding, Charles Winn, E. Danks, J. Freeman, A. Wadley, J. Collier, junr., Joseph Stokes, E. Saunders, W. H. Parton, and W. C. G. Ludford.

only to start again the same year. His third, fourth, and fifth visits to North America were made in 1790, 1791, and 1795, he having in the latter year established a nursery at Sloane Square, Chelsea, to which his discoveries were consigned. Having introduced various American Pines, Oaks, Azaleas, Rhododendrons, and Magnolias, in 1796 he visited St. Petersburg, where the Empress Catherine purchased a collection of plants from him. Revisiting Russia in 1797 and 1798, he was appointed botanical collector to the Czar Paul, and commissioned by him, returned to America in 1799, taking with him the eldest of his two sons.

"In Cuba he met and was assisted by Humbolt and Bonpland. On his return the Czar

Alexander declined to recognise his appointment by his predecessor, though Fraser made two journeys to Russia to obtain remuneration.

"In 1806 he started on his seventh and last visit to America, again taking his son; he returned with many new plants, in 1810, to his nursery, which, however, was never successful.

"He died at Sloane Square on April 26, 1811. His herbarium was presented in 1849 to the Linnean Society, of which he was a Fellow, by his son; but was disposed of in 1863."

The next meeting of the society will be the anniversary meeting, on May 24, at 3 p.m., of which special notice will be given.

BRITISH GARDENERS' ASSOCIATION.

APRIL 30.—The last meeting of the executive council of this association was held at the Royal Horticultural Society's Hall, Westminster, on the above date. Mr. W. H. Divers in the chair. The report of the council for the past year was submitted and passed for the printer. It was decided that members only should be admitted to the annual meeting to be held in the Essex Hall, Essex Street, Strand, on May 29, at 7 p.m., but that all gardeners—whether members or not—would be welcomed to the conference to be held immediately after the meeting. Attention having been called to the low charges for jobbing gardeners in the neighbourhood of Blackheath, the secretary was instructed to write for fuller particulars, and at the same time to intimate to garden owners, by means of an advertisement, that it would be wise to employ only qualified gardeners, and preferably those who held the certificate of the association. *John Weathers, Hon. Sec.*

DEBATING SOCIETIES.

WARGRAVE AND DISTRICT GARDENERS'.

—At a recent meeting of this association a competition amongst the younger members was held in the arranging of five vases of Narcissi for the decoration of a breakfast table, and afterwards a demonstration in wreath-making was given by Mr. E. Windsor, of Holme Park Gardens, Sonning. He explained the various details as his work proceeded, and showed the best manner of wiring flowers and fixing them to the groundwork. The flowers used in the competition, and many others, were sent next morning to the Reading Hospital.

—Mr. T. W. Briscoe, Orchid grower to Messrs. James Veitch & Sons, Langley, read a paper on "Plants from China and Japan and their Collectors," before the members of the above association on May 1. In addition to fresh specimens of many of these Chinese Shrubs, &c., Mr. Briscoe exhibited herbaria specimens of others.

GUILDFORD AND DISTRICT GARDENERS'.

A meeting of the above association was held at the Workman's Hall, Guildford, on Tuesday, April 23, Mr. H. Tann presiding over a good attendance. Mr. W. Wells, Nurseryman, Merstham, Surrey, gave a paper on "Early Flowering Chrysanthemums." The lecturer gave a list of varieties which were best disbudded and another of those which did not require this treatment. By the aid of a lantern Mr. Wells showed a number of insects, some injurious and others beneficial to the Chrysanthemum. This meeting being held on what is known as Hospital Night, several of the members brought cut flowers which were afterwards sent to the Royal Surrey County Hospital. The third annual show of the association will, by permission of Lady Northcliffe, be held at Sutton Place, on Wednesday, July 17. *W. F. B.*

REDHILL, REIGATE, AND DISTRICT GARDENERS'.

—At a largely attended meeting of the above society, held on Tuesday, April 16, Mr. W. P. Bound in the chair, Mr. Paisley, Worth Rectory Gardens, read a paper on "The Cultivation of the Primula." The lecturer said he preferred sowing the seed in September to the general practice of making spring sowings. To obtain large plants for exhibition purposes, it is necessary to give the plants a long season of growth, and as much as 15 months should elapse between the sowing of the seed and the exhibition of the plants. In seed-sowing it was necessary to nearly fill the pot or pans with rough leaves and place about one inch of finely-sifted soil on these and then sow the seeds. The lecturer strongly condemned the practice of placing the plants in cold frames, and advised the use of a low span-roofed house for their accommodation. A temperature ranging from 52° to 55° Fahr. was advocated, with frequent syringings on all favourable occasions. *F. C. L.*

—At a largely attended meeting of this association, on April 21, Mr. Gregory delivered a lecture on "Rock and Water Gardening." The lecturer illustrated his remarks by a number of lantern slides, including views of the Rockery at Kew Gardens and the beautiful water garden at Gunnersbury House. *F. C. L.*

LEE, BLACKHEATH, LEWISHAM, & WEST KENT HORTICULTURAL.

—At the monthly meeting of the above society, held at Church Street Schools, Lee, on Thursday, April 25, Mr. G. Dibley, F.G.S., gave a lecture on "The Non-Flowering Plants." The lecturer prefaced his remarks by exhibiting fossils showing Mosses and Ferns embedded. He also displayed lantern slides that illustrated many points of his lecture.

CROYDON & DISTRICT HORTICULTURAL.

—The spring flower show, held under the auspices of the above society, was held at the Horniman Hall, Croydon, on Wednesday, May 1. The exhibition was open free to the public from three in the afternoon till ten at night, and was inspected by 6,000 to 7,000 visitors.

HANWELL AND GREENFORD HORTICULTURAL.

—A meeting of this society was held on May 1, under the presidency of Mr. W. L. Williams, when Mr. J. Weathers delivered a lecture on the "Herbaceous Border."

Obituary.

DR. ROBERT HAMILTON RAMSAY.—We regret to announce the death on Saturday, May 4, of Dr. Robert Hamilton Ramsay, at his residence, Duncan House, Torquay, after a fortnight's illness. On Saturday evening, April 20, Dr. Ramsay was seized with paralysis of the left side as he was leaving the Torbay hospital. He presided the previous evening at the annual meeting of the local Gardeners' Association, of which he was re-elected president for the fourteenth year in succession. Dr. Ramsay was born in Edinburgh on December 13, 1824, and he was educated at Edinburgh Academy, and Edinburgh and Glasgow Universities. Passionately fond of horticulture, he formed at Duncan House one of the most attractive private gardens in the western counties, and made it one of the beauty spots of Torquay. We have often figured plants from Duncan House Gardens, and one of the most recent was the beautiful plant of *Cordylina Banksii*, which formed the supplementary illustration to our issue for February 23 last. Deceased was a Fellow of the Botanical Society of Edinburgh, and president of the Torquay Sick Gardeners' Relief Fund, which has been of much service to gardeners.

WILLIAM TEMPLE.—We have to record the death of this well-known gardener on May 1. Deceased, who was 72 years of age, was for 36 years head-gardener at Burley-on-the-Hill, Oakham, the residence of the Right Hon. G. H. Finch, M.P. Mr. Temple retired from active service early in the present year owing to indifferent health. He was a thorough all-round gardener,

THE LATE WILLIAM TEMPLE.

and his aid as a judge was often sought at the local exhibitions. Deceased is the last of an old family of Scotch gardeners. His father was gardener and steward to Captain Cheaps. Deceased served his apprenticeship at Balbirnie Gardens, and he also worked in the gardens at Whittinghame. He leaves a widow and three daughters. The funeral took place at Oakham on May 8.

GRAHAM McCULLOCH.—This gardener died at Chelmsford, Essex, on the 2nd inst. Many years ago deceased was a pupil of the late Mr. H. McIntosh, of Drumlanrig Gardens, Scotland, and later, when gardener to Viscount Powerscourt, at Powerscourt Castle, County Wicklow, the late Mr. McCulloch was a leading exhibitor at the Dublin show.

ABRAHAM DIXON.—The death of this gentleman occurred on Tuesday, April 30, at the advanced age of 92 years. Deceased was a well-known horticulturist, and our pages have contained numerous references to his famous gardens at Cherkley Court, Surrey. He was a great lover of plants of all kinds, but his especial favourites were tropical plants and exotic fruits. Mr. Dixon had a collection of aquatic plants, and a special house was constructed for their culture. It was here he cultivated the *Victoria regia*, and in our issue for January 3, 1885, p. 17, it was stated that a plant of this remarkable aquatic was then in flower, and it was described "as the finest in flower and foliage that had been produced in this country." Speaking of the water plants at Cherkley Court the same article stated "it may be said that it would be difficult to name a cultivated species which would not be found there in superb con-

dition." The Yews at Cherkley Court are amongst the noted trees in this country, and they are referred to in Mr. Lowe's *Yew Trees of Great Britain and Ireland*. The trees cover an area of from 90 to 95 acres, and are probably the finest collection of Yews in existence. One is of a remarkably rotund shape, and has been described as the Cauliflower-shaped Yew tree. See fig. 126.

THE WEATHER.

THE FOLLOWING SUMMARY RECORD of the weather throughout the British Islands, for the week ending May 4, is furnished from the Meteorological Office:—

GENERAL OBSERVATIONS.

The weather during this week was cold and unsettled. Falls of rain or hail occurred almost daily, but there were, nevertheless, frequent intervals of clear sky, especially over England. Thunder or thunder and lightning prevailed at Ventnor and Lowestoft on Monday and at Tunbridge Wells on Thursday.

The temperature was below the normal, the deficit varying as a rule between 8° and 4°. The highest of the maxima were registered either early or quite late in the week. In Scotland W. the thermometer touched 62°, and in the Midland Counties 60°, but in most other parts of the Kingdom it did not exceed 57° or 58°, and in Ireland N. it only touched 54°. The lowest of the minima were recorded on Sunday, and ranged from 38° in Scotland E. and England S.W. to 33° in England E. and to 30° in the Channel Islands.

The mean temperature of the sea.—On some parts of the south-west and west coasts the sea was more than a degree colder than during the preceding week, the decrease at Plymouth being 2.8°. On the north-east coast of Scotland, on the other hand, there was a moderate increase of warmth. The actual values ranged from 51° at Newquay to about 45° on the north and north-east coast of Scotland and to 43.6° at Burnmouth.

The rainfall exceeded the mean in all districts, the excess being large generally, but small in England N.E. and Ireland S.

The bright sunshine did not differ very materially from the average over the kingdom generally. The percentage of the possible duration ranged from 46 in the Channel Islands and 45 in England S.W. to 31 in England N.W. and to 26 in Scotland N. and E.

THE WEATHER IN WEST HERTS.

Week ending May 8.

One very warm day, and one moderately cold night. On the whole a warm week. There occurred one very warm day when the temperature in the thermometer screen rose to 70°, or to the same temperature as on April 24. On the one cold night the exposed thermometer showed 8° of frost. Notwithstanding the recent moderately warm weather the ground, both at 1 and 2 feet deep, is now about 1° colder than is seasonable. Rain fell on four days to the total depth of half an inch. There has been some percolation through both the soil gauges during the week, but the amounts for the last few days have been very small. The sun shone on an average for 6½ hours a day, or for about an hour a day longer than is usual at this season. The winds remained high throughout the first four days, but since then have been light. On two days in the windiest hour the mean velocity was 20 miles, direction respectively W.S.W. and W. There was about a seasonable amount of moisture in the air at 8 p.m. A Blenheim Orange Apple tree growing in my garden first showed an open blossom on the 4th, which is two days earlier than its average date for the previous 21 years, and one day earlier than last year. *E. M., Berkhamsted, May 8, 1907.*

TRADE NOTICE.

APPOINTMENT.

Mr. G. HARROW, late of The Abbey Nurseries, Leicester, has been appointed Manager to Messrs. JAMES VEITCH & Sons, Ltd., Coombe Wood Nursery, Kingston-on-Thames.

ANSWERS TO CORRESPONDENTS.

* * * The Editor will be glad to receive, for consideration, large photographs of horticultural subjects, suitable for forming Supplementary Illustrations to this Journal.

ARUM WITH SPATHACEOUS LEAF: F. B. S. This abnormal condition is not uncommon.

CARNATIONS: E. B. We failed to find the worms, but suspect from your description, and the condition of the plants enclosed, that the soil is in a sour condition. Mix some lime with the loam which will neutralise the acidity. Sprinkle some soot also amongst it, for this will both furnish food and be a deterrent to the insect pests. The layers you forwarded had apparently failed to develop any roots.

CHRYSANTHEMUMS FOR PLANTING OUT: H. J. G., Preston. It would not be advisable to cut the Chrysanthemums back so close to the base as 1 inch in the present state. It would encourage suckers and these would prevent the main stems breaking into growth freely. They might have

been treated in the manner you suggest if they had been established in small pots. The plants having been in the cutting-boxes since December they need shifting, or they will become so impoverished as to be useless. If you cannot plant them out permanently at once, we should advise transplanting them into temporary beds, putting them at some 6 or 8 inches apart each way. Pinch them back to two or three joints as soon as they start into fresh growth. Remove them to the permanent quarters before they become too crowded, and stop them for the second and last time when they have become established. It does not follow that if the plants are checked severely in their early stages the blooming period will thereby be retarded, such treatment often has just the opposite effect.

EARWIGS: J. S. S. Try the old plan of the inverted flower pot filled with hay. Drive some stakes in the border at the foot of the wall, and on these place the inverted pots. These pests can also be trapped beneath pieces of slate.

EMIGRATION TO NEW ZEALAND: A. J. Your enquiry respecting the best means of securing a situation as a gardener in New Zealand arrived almost by the same post as a letter from a correspondent at present in Auckland, N.Z., upon the same subject. The following is the substance of his letter: "Will you permit me to warn gardeners, young and old, against coming to the colony. My experience is only based on eight months' residence, but it is enough, I hope, to stop further gardeners from coming. I have advertised 24 times in the two daily papers here, and yet cannot get even a full week's work jobbing. There are scarcely any permanent situations here. The gardener has to milk a cow, attend to a horse, and do other odd jobs. I hope to come home again as soon as I can get money equal to the cost of my passage both ways. The pay here in nearly all cases for garden work is 6s. per day; a gardener can very rarely get 7s., and he has to work for more hours than in England. Chinamen practically control the vegetable trade, and I know on good authority that leading Chinamen pay the £100 poll tax, so that they have to pay that money back in work. I am only writing of the conditions in Auckland, but have a friend in Wellington and he has had similar experience to myself. There are no garden papers published here, and at the time of writing I have had to go navvying. As far as I can gather navvies and farm hands are all that are wanted here. I have had 14 years' experience in good gardens at home (England), including Chiswick House, Dyrham Park, and Brockley Hill, Stanmore. —G. HARDING, Ponsonby, Auckland, N.Z., March 12, 1907." In reply to your question respecting advertisements, if you inserted one in a paper published in England, it would be five or six weeks before the advertisement could be circulated in New Zealand.

FUCHSIAS FAILING TO GROW: J. W. The growing points appear to be injured by mites. Dip the plants in tobacco water.

GOOSEBERRY FRUITS: G. D. The blossoms were properly fertilised and the injury to the fruits has been caused by a check, probably frost.

INSECTS: A. A. W. The insect is *Andrena fulva*, one of the solitary burrowing bees which make their nests in the ground, frequently choosing gravel paths or short turf for the purpose. They form, according to the species, vertical tunnels from 5 to 10 inches in length, some with short horizontal ones leading from them. The bee places a pellet of pollen mixed with honey at the bottom of the tunnel on which she lays an egg, she then forms a partition across the burrow, procures another little mass of pollen and honey, lays another egg, makes another partition and continues the work until she has sufficiently filled the burrow with cells. The grubs, when hatched, feed on the food provided for them by their mother; when this is finished they undergo their transformation to the chrysalis state, in which condition they remain until the following spring, unless there are two broods which is the case with some species. We do not remember, however, having seen a second brood of *A. fulva*. If you wish to destroy these insects, probably the simplest way would be to thrust a strong wire or thin iron rod into the tunnel for the depth of a foot and then to pour in a strong solution of paraffin emulsion, or fill the hole with lime.

MELON: H. J. D. The roots have decayed owing to excess of water or fertilisers. There is no injury caused by fungi or insects. See also answer to B. E. H. in last week's issue, p. 292.

MELON LEAVES: W. P. The blistering is caused by the presence of too much moisture in the atmosphere. Better ventilation will remove the cause. There is no fungus present.

STRAWBERRY: W. H. D. It is uncommon for a second Strawberry to be produced in the axil of the first as in your specimen, but the production of a leaf or leaves from the fruits situate on the outside of the edible portion of the Strawberry is not so rare an occurrence. The edible portion of the Strawberry is the top of the flower stalk which dilates and becomes succulent. The "seeds," as gardeners sometimes call them, are fruits or seed vessels, and therefore carpels. Carpels are only modifications of leaves, and occasionally, as in this case, they may develop into leaves. The swollen receptacle being a portion of the stem it is not surprising that it should occasionally produce little buds and little growths as shown in the accompanying illustration. It may be added that in the small secondary Strawberry you have sent us there is

FIG. 123.—A PROLIFEROUS STRAWBERRY.

also medial proliferation, which means that the receptacle is prolonged into a leafy branch extending beyond the edible portion of the Strawberry.

NAMES OF FLOWERS, FRUITS AND PLANTS.—We are anxious to oblige correspondents as far as we consistently can, but they must bear in mind that it is no part of our duty to our subscribers to name either flowers or fruits. Such work entails considerable outlay, both of time and money, and cannot be allowed to disorganise the preparations for the weekly issue, or to encroach upon time required for the conduct of the paper. Correspondents should never send more than six plants or fruits at one time: they should be very careful to pack and label them properly, to give every information as to the county the fruits are grown in, and to send ripe, or nearly ripe, specimens which show the character of the variety. By neglecting these precautions correspondents add greatly to our labour, and run the risk of delay and incorrect determinations. *Correspondents not answered in one issue are requested to be so good as to consult the following numbers.*

PLANTS: A. P. *Cymbidium eburneo-Lowianum*, a cross between *C. eburneum* and *C. Lowianum*. —*Learner*. 1, *Tydaea insignis*; 2, *Begonia nitida rosea*; 3, *Begonia hydrocotylifolia*; 4, Probably *Polygonum baldschuanicum*. Send when in flower. —*H. R.* Similar varieties of *Pyrus Cydonia japonica* have originated in nurseries and have received names. We cannot undertake to identify them. —*Cooper*. 1, *Amelanchier canadensis*; 2, *Taxodium sempervirens*. —*C. E. A.* *Megasea cordifolia*, often called *Saxifraga*. —*E. C. C. D.* *Saxifraga cymbalaria*. —*T. G.* *Cranbrook*. 1, *Amelanchier canadensis*; 2, *Carpinus Betulus*; 3, *Abies Nordmanniana*; 4, *Cornus Mas*; 5, *Cotoneaster frigidus*; 6, *Thuya dolobrata*. —*H. J. M.* 1, *Doronicum caucasicum*; 2, *Sedum spectabile*; 3, *Polemonium coeruleum*; 4, *Pulmonaria officinalis*; 5, *Omphalodes Lucilia*; 6, *Diosma ericoides alba*. —*J. M.* 1, *Strelitzia Regina*; 2, *Sprekelia formosissima*; 3, *Polygala Dalmatensis*. —*J. H.* *Primula japonica*.

—*V. I.* 1, *Oncidium varicosum*; 2, *Lycaste tricolor*; 3, *Maxillaria variabilis*; 4, *Megaclinium falcatum*. —*R. F.* 1, *Acer Pseudo-platanus* var. *purpurea*; 2, *A. Negundo variegata*; 3, *A. Negundo aurea*; 4, *A. platanoides*; 5, *Alyssum saxatile*; 6, *Choisya ternata*. —*C. W. T.* 1, *Cotoneaster frigidus*; 2, *Prunus* species; 3, *Kerria japonica*, double var.; 4, *Berberis stenophylla*; 5, *Pyrus Maulei*; 6, *Prunus sinensis flore pleno*; 7, *Pyrus Malus atropurpurea*; 8, *Cornus Mas*, variegated form. —*A. I.* *Geranium phaeum*. —*A. F. W.* 1, Not recognised, send when in flower; 2, *Rosmarinus officinalis* (Rosemary); 3, *Melittis melisophyllum*; 4, *Ruta graveolens* (Rue); 5, Not found; 6, Not recognised. —*A. H. A.* *Prunus pseudo-cerasus* variety.

FRUITS: J. J. B., Worcester. 1, Northern Greening. —*A. F. Salop*. 1, Northern Greening; 2, Not recognised, most likely a local variety.

PALM ROOTS: J. S. Soak the roots in a rose-red solution of permanganate of potash for two hours.

PROTECTION OF FRUIT ON WALL-TREES FROM WASPS: J. S. S. Take the measures recommended on p. 299, under "Apiary," for lessening the number of wasps. When the fruits commence to ripen let the trees be protected by the use of hexagon wasp-proof netting obtainable from the horticultural sundriesmen.

PTERIS FERN: Correspondent. The leaves show injury by thrips and other pests, which have developed in consequence of the plants having been grown in a hot, dry atmosphere. Dip the plants in tobacco water, and afford them more atmospheric moisture and less artificial heat.

RATES FOR MARKET GARDEN: W. E. A. So far as rates levied under the Public Health Act, 1875, are concerned, if your nursery-grounds are in an urban district you ought only to be assessed in the proportion of one-fourth of the net annual value of the land, and it is immaterial whether the land is covered with greenhouses or not. In the case of rates levied under the Agricultural Rates Act, 1886, the rule is different. Under this Act you are liable to pay one-half of the rates in respect of so much of your land as is not covered with buildings, but greenhouses are buildings for the purposes of this particular Act. You should call the rate-collector's attention to the provisions of the above Acts.

STEINER'S VERMIN PASTE: S. H. C. You should ask the local chemist to obtain it for you from a wholesale establishment. Phosphorus Paste is very useful for the purposes you require.

VINE LEAVES: W. V. and A. B. The leaves are infested with *Botrytis cinerea*. Spray the plants thoroughly with a solution of potassium sulphide 1 ounce in 3 gallons of water. Admit as much air to the structure as circumstances will permit.

WATER MELONS: Anglo-Scot. You have been misled by this popular name for *Citrullus vulgaris*. The term Water Melon has no reference whatever to the plant requiring its roots to be near to a river or stream, but probably to the fact that the great fruits when ripe contain an enormous percentage of water themselves. There are probably more Water Melons cultivated in the United States than any other part of the globe, and the *Cyclopedia of American Horticulture*, when referring to the culture of Water Melons in Georgia, states that "like the cat and the Grape the Melon cannot bear 'wet feet.'" Your stream, therefore, would be of no use for such a purpose, and, further, this country is quite unsuited for the culture of Water Melons, the summers being much too cool for their growth. If you wish to cultivate Melons and have not the means to grow the best types of English hot-house Melons, you should select the Cantaloupe type, varieties of which may be grown in frames without very much artificial heat. See an exhaustive article on this subject published in the *Gardeners' Chronicle* for December 28, 1901, p. 495.

OBSERVATIONS IN FRUIT PLANTATIONS.

VARIATIONS in the order of blossoming among different varieties of Plums in different seasons are curious. Last year the variety Black Diamond was the first to show blossom, and this was followed by Early Rivers and a few trees of Monarch which bloomed together; then Victoria, Czar, Pond's Seedling, and Gisborne's blossomed in the order given. This season Monarch and Black Diamond were first in flower, both being fully out on April 24th. Victoria came next, being three-quarters out on that date, while Czar and Early Rivers were about one-third out, but Pond's Seedling and Gisborne's were quite unopened on that date. There is no connection between earliness in blooming and in ripening, as is shown by the fact that Monarch, the latest of the Plums named, was equal first with Black Diamond in blossoming. Amongst varieties grown in small numbers only here, Coe's Golden Drop was ahead of Early Rivers and Czar in flowering, though it ripens much later, and it was considerably in advance of Oullin's Golden Gage, Old Greengage, Denniston's Superb, and Early Transparent Gage.

As the birds have not injured the buds of these choicer varieties this season, the trees are showing a fair amount of blossom, but they are not profusely covered with flowers, save in the case of Oullin's Gage, and certainly not so heavily as in the sorts grown on a large scale for market. Trees of the variety Victoria showed a magnificent display of blossom, all but last season's wood being thickly clothed with strong bloom. Purple Gage (Reine Claude Violette) is the only variety of Plum that was almost devoid of blossom this season. Whether it is regularly a shy bearer or not I cannot say, as I have had no experience with it, except with two trees which are less exposed to the sun than other trees in the same orchard.

Worcestershire Prune Damsons, planted six years ago from last autumn, were profusely covered with blossom for the first time. From 160 of these trees, planted to shelter Apples, I have not had a bushel of Damsons in the five seasons up to 1906 inclusive. This season each tree promises to produce a bushel of fruit. The trees came into blossom simultaneously with Monarch Plum.

One observation on Plums is connected with the extension system "run mad." I wish Mr. Simson could have seen my trees of Victoria Plum before they were pruned. Nearly every new shoot—in many an instance a yard or more in length—was bow-shaped, and in many cases one branch was hanging over another. This has been the style of growth ever since the trees were planted, and it may be imagined what the trees would have been like if they had not been pruned annually to buds pointing upwards. They would have presented a tangled mass of branches bending towards, and many of them touching the ground, whilst, at the same time, the branches would have been much too thinly disposed, particularly in the centres of the trees. As it is, they are thoroughly well furnished with sufficiently sturdy branches.

Hitherto no frost has harmed the Plum blossom in this district. There were 4° of frost on two occasions after Monarch and a few other varieties were showing bloom; but not the slightest damage is noticeable, even to blossoms facing upwards, though in low situations in the Evesham district some damage is reported to have been done. I am, however, sorry to record the presence of the dreaded Plum aphid. The pest was first noticed on a few leaves on many trees on May 6. It was expected to follow the bruising of the foliage by the violent gale of May 2; for, although it is not clear why this should be, the pest always seems to attack injured vegetation most severely. The popular idea among farm labourers and others is that east winds "bring" the green fly, but there is no way of accounting for cold winds acting as the agency, except so far as the checking action of a cold wind gives the pest a chance of making a successful attack upon tender foliage. Whence the enemy came—where it was harboured—is a mystery to me. Careful examination at the bases of hundreds of fruit buds, where the brown or purplish viviparous females are stated to be harboured in a quiescent state, failed to reveal any. Now there are only too many, as well as their progeny, the green lice. Spraying with soft soap and quassia has been performed in the hope of checking the spread of the pest, protected

though it is in the curled leaves. Last year the trees were smothered with this aphid.

Several trees of all varieties of Apples have been examined, but only seven aphides have been found on them. Better still, not a single Apple sucker has been seen.

APPLES.

Here and there an Apple blossom was open on April 27. Irish Peach was the most forward, and this variety was closely followed by Bismarck, Warner's King, Stirling Castle and Duchess of Oldenberg, while Early Julien and Blenheim Pippin were a little later in expanding their flowers. Here, again, the connection between early blooming and the ripening of the fruits is by no means uniform, Bismarck's flowering nearly coinciding with the early-ripening Irish Peach, and both were in flower before Mr. Gladstone, the earliest Apple to ripen in the plantation. Again, Warner's King is ahead in its flowering of the earliest cooking Apple in the plantation—Early Julien. Allington Pippin was earliest in leaf expansion, but it is much behind those named in blossoming.

The promise of Apples is, on the whole, good, but not quite equal to that of last year, especially in the case of some of the varieties that bore heavy crops in 1906. Allington Pippin, which has yielded remarkably well from an early age, and was allowed to bear too freely last season, promises only half a crop this year. This is also the case with Domino, the fruit of which was not sufficiently thinned last season. Golden Spire with me fruits in alternate years. It yields very heavily in one year, but is almost always devoid of fruit in the season following. Last year it cropped heavily, and this year only trees that missed fruiting last year are blossoming freely. Possibly Domino is also an alternate yielder. If so, I shall regret having planted many trees of that variety in my new plantation.

CHERRIES AND PEARS.

Early Cherries came into bloom simultaneously with the earliest blossoming Plums. As usual, there was a great show of blossom which was remarkably vigorous. Pear blossom expanded quite suddenly, late varieties being close behind early sorts in opening, and this was probably due to three hot and sunny days ending on April 25. There was a great profusion of Pear bloom, but this is so often followed by a light yield of fruit that no confidence can yet be felt as to results. In a record extending over 14 years previous to the present one, there is no entry of later blossoming of Pears than that of this season. In 1903 early varieties were in full bloom on March 31, and this is the earliest record of blooming in Pears that I possess, though it is closely followed by that of 1905, when a few blooms expanded on the same date. Next in earliness was April 7, in 1894, while April 15 was the date in at least two other seasons. The season of 1903, it may be added, was an exceptionally early one for all classes of vegetation, early-blossoming Plums, as well as early Pears, being fully expanded in flower on March 31, whilst early Apples were in bloom on April 15, and spring flowers were all correspondingly forward.

BUSH FRUITS.

Gooseberries have rarely been as late in blossoming as they were this season, April 14.

being the date of their full expansion. In 1903 and 1905 it was March 31. The promise of the crop is a very good one in my case, as birds did not attack the buds after the bushes had been sprayed. Black Currants are later in the blossoming stage than they have been in any previous season since my records were commenced. The blossoms have often been expanded by the middle of April, and this year none was out on April 27. Red Currants, on the contrary, were as forward as Gooseberries, being fully out on April 14. Usually this fruit is a week or two behind the Gooseberries in flowering. Both Red and Black Currants promise well.

Strawberries, grown only in my private garden, where the soil is not heavy enough for them, showed a blossom or two only on April 27; and Raspberries had then only just begun to show a few flowering buds.

Fully double the average of rain for the month has been registered during April, and this will be helpful to all kinds of fruit trees, provided that sunny weather follows: for young plantations of trees and bushes it will be especially beneficial. *A Working Grower.*

NEW OR NOTEWORTHY PLANTS.

CLEMATIS SANDERI.

IN a cold greenhouse at St. Albans there is now flowering a Clematis which differs from all other species known, in having white flowers with a conspicuous brush-like cluster of salmon-red stamens. Messrs. Sander & Sons obtained the plant three years ago from Australia, where it was discovered wild on a mountain, they do not say where. In a very broad sense it is *C. aristata*, found everywhere in Australia, and, consequently, a very variable plant, so variable indeed that some botanists would make a dozen or more species out of it. The type was figured in the *Gardeners' Chronicle*, July, 1902, p. 55, and has large ovate lanceolate leaflets and white flowers with green anthers. The form there represented is a male, but the female form is now in flower at Kew. *C. Sanderi* is quite distinct from these. It is an evergreen, with the habit of *C. indivisa*, but is less robust; the leaflets are narrow-lanceolate, 1 to 2 inches long, markedly dentate, and dull green. The flowers are in axillary clusters, sometimes occurring in bunches of a dozen or more; they have a slender, straight pedicel 2 inches long; the four white sepals are an inch long, narrow, and elegantly recurved, and the stamens (this plant being a male) are half-an-inch long, and form a regular, double-daisy-like cluster, their bright salmon-red colour making them attractive and pleasing. The flowers are very fragrant and lasting. *W. W.*

THE FERNERY.

FERN DIMORPHISM.*

THIS book is a very interesting contribution to this branch of research by Dr. H. Christ, of Basle, with special reference to the genus *Stenochloa*. The Ferns forming this family occur in the tropical forests, and commencing by rooting into the soil, ascend very high trees by means of creeping rhizomes, whence the fronds spring successively. The peculiarity dealt with by Dr. Christ is their production of two quite different kinds of fronds, independently of the difference

between the barren and fertile ones, the latter being contracted. Normally the fronds are once divided, the side divisions being lanceolate if barren, but linear if fertile. These forms, however, are those which characterise the higher growing portions of the plant, but at the ground level or near it the growing rhizome is densely clothed with small fronds of a much divided character and of such different appearance as to have misled numerous botanists, the result being their allocation to the genera of *Asplenium*, *Davallia* and others. A singular feature in these fronds is that they are not merely different in form and cutting, but they approach the prothallus in the nature of their cellular structure, and furthermore they occasionally produce pseudo-sporangia and pseudo-indusia of the *Asplenium* type, which Dr. Christ considers as evidence that the *Stenochloa* family has diverged from *Asplenium*. The production of these almost *Hymenophyllum*-like basal fronds he considers as an evolutionary outcome of the need of provision to the higher placed fronds (growing perhaps 20 or 30 metres high in the crowns of the trees), of a water

suggested that the decomposed basal fronds are due to the same cause as has led to the formation of dimorphic leafage of the Water Crowfoot, the damp and shady conditions at the foot of a tree representing the submerged conditions of the decomposite leaves of that species, while the lighter and drier conditions prevailing above induce simpler foliage and consequently reduced transpiration. I can hardly imagine, too, that a climbing Fern of the type described depends very greatly upon a basal water supply for its upper growths; epiphytal Ferns usually root freely as they progress, and thus obtain a local supply from the bark and debris they encounter in their progress. *C. T. D.*

PLANT NOTES.

ERINACEA PUNGENS.

ALTHOUGH introduced from Spain in 1759, this plant is still rare in gardens, owing, perhaps, to its not being perfectly hardy in the

FIG. 129.—ERINACEA PUNGENS IN CAMBRIDGE BOTANIC GARDENS. FLOWERS BLUISH-PURPLE.

supply which such a growth near the ground and in the shade would assist in furnishing. There are numerous illustrations showing the difference between the lower and the upper frond systems, and also the one merging into the other. He also cites the existence of an *Asplenium* with similar habit of growth, which also produces tripinnate fronds when young, these being followed as the rhizome climbs to the light by fronds like those of *Stenochloa*, but with the *Asplenium* fructification, such as is seen in pseudo form on the young *Stenochloa*, fully developed. The notes have a practical interest for Fern raisers, as the extreme difference of the young plants from the adults is very likely to mislead, and from the facts given it may also be deduced that under cultural conditions of shade and moisture the higher type of frond might not appear at all, and a *Stenochloa* seedling would thus be taken for a *Davallia* or other imitated species. As opposed to Dr. Christ's conclusions, it might be

colder localities of this country. It is, however, well worthy a trial in a sunny, sheltered position on the rockery or elsewhere, and under favourable conditions it forms a much-branched, spiny, and almost leafless little bush, 9 inches in height, and a foot across. The flowers are produced during the summer months, six or eight together, on a short inflorescence, and they are of a bluish-purple colour. The photograph represents a plant growing in the Cambridge Botanic Gardens in a sheltered position at the foot of a south wall, in which position it flowers splendidly each summer. It is a somewhat difficult plant to propagate, but this can best be accomplished if the cuttings are inserted in sandy soil in the autumn and placed in a cold frame, where some of them will commence to sprout the following spring. Like many other plants, it is known under several names, two of which are *E. hispanica* and *Anthyllis erinacea*. *E. J. Allard, Botanic Gardens, Cambridge.*

* "Fern Dimorphism," by Dr. Christ.

THE GENUS ENKIANTHUS.

This small genus of Ericaceous plants is peculiar to Eastern Asia, extending from the Eastern Himalaya through China to Japan. Some nine species are at present known. Three of these are peculiar to China, five to Japan, and one (*E. himalaicus*) is common to Western China and Eastern Himalaya. *E. quinqueflorus*, on which the genus was founded, is native of Hong Kong and the warmer parts of South-eastern China; a variety occurs in Hupeh and Yunnan. The rest of the genus inhabit the hills of the regions mentioned above, and in China ascend up to 11,000 feet altitude. The species found in Central and Western China are remarkable for the richness and brilliancy of their autumnal tints, which vary from bright yellow to the richest crimson, and are peculiarly fascinating. The Japanese species probably exhibit similar phenomena, but I can find no reference to such as the yellow tints of *E. japonicus*.

The species found in temperate China are social in habit, forming thickets on precipitous humus-lad cliffs, and are usually associated with *Rhododendrons*. All are remarkably free-flowering, and their presence when in flower may be easily detected by the ground beneath them being strewn with fallen "bells."

E. quinqueflorus, the "Tiao Chung" (suspended bells), is one of the flowers most highly prized by the Chinese. It blossoms in February and March, about the time of their New Year, and is used in great quantities for the decoration of their houses, temples, and guild-halls. The branches are gathered whilst the flowers are still in the bud stage, and on being placed in water soon open and last fresh for a considerable time. A little before the Chinese New Year the Tiao Chung, with *Pæonia Moutan*, Heavenly Bamboo (*Nandina domestica*), and double-flowered peaches, is on sale in the streets of all the towns from Shanghai (at least) south. This species is still fairly plentiful in Hong Kong and the adjacent mainland, where ruthless gathering is prohibited. The other species are not particularly valued by the Chinese, though they are not less beautiful.

Most of the species are now in cultivation in this country, but not with any great success, and good examples are rare. *E. quinqueflorus* is, of course, too tender for general outside culture in this country, and most of the others suffer from our late spring frosts, at least in the neighbourhood of London. All the species are slow-growing and rather difficult to establish, yet so beautiful are they that it is to be hoped more attention will be paid to them in the future than has been the case in the past. Like the great majority of Ericaceæ, *Enkianthus* are regarded as peat-loving plants and are usually treated in the same way as *Rhododendrons*. They revel in sunshine, at must never suffer from drought at the roots. In their native habitat the Chinese species, at any rate, do not have peat to grow in but content themselves with the thin layer of humus covering the granite rocks. The climate is one where a copious rainfall alternates with bright sunshine.

Enkianthus are easily raised from seed, and seedlings grow away fairly rapidly. Cuttings of one or two years old wood inserted in sandy peat, under glass, in a cold frame in spring, will make roots though not very readily, and they require great care in potting and transplanting. This same care is necessary in transplanting at any stage.

The species are nearly all twiggy in habit, with the branches more or less whorled, and the leaves clustered at the ends of the shoots. The flowers are always pendulous, and either bell or urn-shaped. In colour they may be white, as in *E. japonicus*, or rose-coloured or rose and white, as in *E. quinqueflorus*, but in the majority of the species they are yellow, suffused, or striped with red.

This genus was founded by Loureiro on the South China plant (*E. quinqueflorus*) but he "mistook the coloured bracts for the calyx, the young leaves for the corolla, the real flowers for the floscule of a compound aggregation of florets." (Lindl. *Bot. Reg.* under tab. 884.) With such a bad beginning it is only to be expected that confusion should obtain as fresh species were discovered. In dealing with the subsequently discovered Japanese species, Miquel (*Ann. Mus. Lugd. Bat.*, i.) placed them all under *Andromeda*, and associated *Pieris* with the same genus. *Enkianthus* differs from *Andromeda* technically only in the seeds, which are large with a lamellate winged testa, whilst in the latter genus they are small with an appressed smooth testa. In habit, however, they differ widely, *Enkianthus* being really much more closely allied to *Pieris*, but very readily distinguished therefrom. Maximowicz and others followed Miquel in part, and it is only very recently that all the Japanese species have been placed under the right genus. The species are still much confused as we shall show presently.

Palibini in a very excellent paper (Rev. Gen. *Enkianthus* in *Script. Bot. Hort., Petrop.*, fasc. xv., 8) compiled a workable key for the genus which, with one important alteration and some modifica-

III. *ANDROMEDINA*.—Fruits pendulous, flowers racemose, appearing after the leaves; corolla five lobed, urn-shaped—*E. subsessilis*.

IV. *MEISTERIA*.—Fruits pendulous, flowers racemose, appearing after the leaves; corolla campanulate, lacinate-dentate.

Corolla three or four times the length of calyx-lobes, filaments twice the length of the anthers—*E. Meisteria*. 'E. H. Wilson.

(To be continued.)

CUSHION PLANTS.

IN hot, dry, wind-swept regions plants not infrequently assume a "polster," or cushion-like appearance, as shown in fig. 130, copied from the *Annalen des K. K. Naturhistorischen Hof-Museums of Vienna*. The plant represented is not a Cactus, though it might be mistaken for one. It really is a member of the family *Plumbaginaceæ*, named *Acantholimon Echinus*. We are not answerable for the name, we simply illustrate the plant to show how subjects of the most varied affinity may assume the same habit when exposed to the same conditions. The plant has to contend against drought, extremes of heat, cold, wind, and the ravages of browsing animals. How it does this is well shown in the illustration. We are not aware whether this particular species of *Acantholimon* is in cultivation or not, but there are others such as *venustum* and *glumaecum* which are excellent plants for the rockery, and in addition to their compact habit and spiny leaves bear very attractive rosy flowers. In the Chelsea Botanic Garden, now under the excellent management of Mr. Hales, we have known one of these species on the rockery surrounding the pond in the centre of the garden for at least half a century, a circumstance that shows that it has great powers of adaptation not only to conditions such as exist in Asia Minor, but also to those which surround it on the banks of the Thames and in the midst of a smoky suburb. Drs. Penther and Zedebauer thus speak of these plants in the publication referred to:—

"Characteristic of these regions are the species of *Astragalus* and *Acantholimon* which are found mostly on sandy and stony ground. The cliffs are covered, especially in the eastern districts, with these spiny cushions, which are well protected against the flocks of sheep and herds of goats, which spare no other plants, and owing to which all herbaceous growth by the end of July has been bitten off, and nothing remains above ground for the botanist. A few species seem to be preserved, thanks to the protection of the thorny tufts, as they are able to proceed with their growth through the middle of them. In this way only have I ever found, for example, *Cerastium argæum*, in the *Astragalus* cushions."

"By what means is this cushion-like shape produced, and what advantage does it bring to the plant? One of its chief causes is the rough wind which blows almost daily over the barren and treeless slopes. By causing too much drought (of water) the growth of the plants in height becomes checked, and the production of numerous side-shoots ensues. The inner part of the cushion-like plant holds the water longer, and evaporation, therefore, is less. This prevention of evaporation produces the needle-shaped leaves of *Acantholimon* and the small, hairy leaves of the species of *Astragalus*."

FIG. 130.—A "CUSHION" PLANT: ACANTHOLIMON ECHINUS.

tion is adopted below. Palibini dealt with the Japanese species in a masterly manner, but evidently he had not seen specimens of the more recently discovered species from China.

I. *EUENKIANTHUS*.—Fruits erect; flowers in umbels appearing before the leaves; corolla unequal at base from the presence of five large nectaries.

Flower-stalks curved downwards, corolla campanulate, gibbous at base—*E. quinqueflorus*.

Flower-stalks straight, spreading; corolla urn-shaped or globularly so, saccate at base—*E. japonicus*.

II. *ENKIANTELLA*.—Fruits pendulous; flowers appearing after the leaves; corolla five lobed, equal at base.

A. Flowers sub-umbellate.

Leaves serrulate-aristate, hairy; anthers, style, and ovary glabrous; fruit ovoid—*E. campanulatus*.

Leaves serrulate, hairy; anthers, style, and ovary setulose; fruit globular—*E. himalaicus*.

Leaves serrulate, glabrous—*E. chinensis*.
B. Flowers solitary, rarely in pairs—*E. pauciflorus*.

THE FERN-HOUSE IN THE BRUSSELS BOTANIC GARDEN.

A RECENT number of the *Tribune Horticole* mentions that the large Fern-house in the Botanic Garden in Brussels has been greatly altered. M. Dumilieu, a well-known designer of rockeries, has veiled the end wall of the house with a rock-work simulating the entrance to a cave, and in the interstices are set plants of appropriate foliage. Varieties of Sansevieria, Philodendron, Begonias, Ferns, are there, and two large *Livistona australis* are arranged one on each side, as well as large specimens of *Howea* (*Kentia*) *Forsteriana*. From the top, which is reached by a flight of irregular steps cut in the rock, the water flows in a cascade into a basin and then runs into a brook that winds across the house. This large Fernery includes some fine Tree-ferns, principally from Brazil: *Cyathea arborea*, 82 feet high; *C. Schanschin*, 16 feet; *C. medullaris*, 22 feet; *C. insignis*, 19 feet; *Alsophila armata*, about 10 feet; *Cibotium regale* with a trunk measuring 6½ feet, bearing 10 leaves, 16 feet in span; *C. Wendlandi*, the trunk 8½ feet, with 10 fronds; *C. Schiedeii*, trunk 2½ feet, with 16 fronds; *Angiopteris evecta* var. *Teysmanniana* from Java, 6½ feet in circumference and with 14 fronds; while among Palms especially noticeable are three *Howea* (*Kentia*) *Forsteriana*, 82 feet high; *Livistona australis*, 89 feet; and *Pandanus furcatus*, 92 feet high and 26 feet across.

ROYAL ACADEMY, 1907.

FOR several years past garden subjects, and pictures of flowers and fruits have been badly frozen out from the annual exhibition of paintings at Burlington House; the old aggressive smears of yellow and red stated to be representations of Daffodils and Roses have either been kept at home, or sent elsewhere. Portraits are again strongly in evidence, gentlemen with golf-sticks, guns, fishing-rods, swords, and sham rolls of MSS., huntsmen with hunting whips and dogs, others with motorcars, are plentifully represented, the maximum representing idleness, the minimum work. The ladies are mostly shown smiling in a heartless fashion, either seated in an unusual manner upon sofas, or standing in a set attitude. The portraits are mostly pure commercial products. Next there are the landscapes and seascapes, many of a high class. British artists excel in this work, and many pictures in the Academy give evidence of long and painstaking study. Figure subjects vary greatly. Some exhibit considerable thought, study, and work; others absolutely nothing. There are 1,845 works of art exhibited; perhaps 100 are worth study or possession. In Gallery I., amongst pictures by Leader, Wyllie, and others, and omitting all portraits and figure subjects, are:—21, *Grass Fields on the French Coast* (H. W. B. Davis, R.A.): this stands out as one of the best productions. In Gallery II., *Across the River* (David Murray, R.A.) is a fine, somewhat roughly-executed landscape. 94, *Emblems of Ancient Faith* (Edith Sprague), seems to be a floral subject, perhaps with *Pyrus japonica*, but it is on the skyline and practically invisible. 128, *Roses* (Rose E. Welby) is a well-executed picture of pink and yellow Roses in a regulation ginger jar. 136, *Sunset* (George Clausen, A.), is a powerfully-painted picture of hovels, bushes, a pool of water, and setting sun. 140, *Golden Fruit and Flowers* (E. T. Sutcliffe) (placed over the portrait of the Chief Officer, London Fire Brigade), is an apparently well-executed picture of Oranges (some in tissue paper), cut Lemons, Daffodils, and Violets, with a punnet on edge. However well done this class of subject may be, the tiresome iteration of the objects painted palls on those who have seen hundreds of such before. Gallery III.—*Ceylon Leopards* (J. M. Swan, R.A.): a powerfully-painted but somewhat rough

picture of two very much awake leopards sprawling amongst a profuse growth of Orchids, possibly lying in wait for some nurseryman's Orchid collector. This picture would do well for the Orchid Committee's alcove of the Horticultural Hall. It would illustrate some of the difficulties in the way of collecting choice Orchids. In this Gallery is a second fine work, 188, *Mid-day* (H. W. B. Davis, R.A.). In Gallery V.—322, *Anemones* (R. Willes Maddox): these are purple and white garden Anemones, in a china vase, placed in the middle of the picture, with a bloom or two at the base. There is a fine non-commercial portrait of a distinguished man near by,

Michael's right hand closely resembles a cigarette. Gallery IX. is a room containing small pictures, and here we meet with flowers and fruits. 611, *Roses* (A. Miles Albert), shows, to us, no appreciation of Roses. 616, *Primula* (Mary M. McCulloch): *Primula obconica* in a little vase in the centre of the picture. 625, *Fruit* (A. F. W. Hayward): a bunch of Grapes, two or three unripe Bananas, and a few Cobnuts. Next to this is 626, *The Little Brook* (George Clausen, A.). 655, *White Roses* (Alice van Haddeghem): no good to rosarians. 722, *Roses* (Ethel Woods): extremely rough. Rough work does very well for old thatched cottages, hovels, and ploughed

FIG. 131.—VIEW IN THE FERN-HOUSE IN THE BOTANICAL GARDEN, BRUSSELS.

in 335, *Arthur Evans, Esq.* (Sir W. B. Richmond, R.A.). Further on is *Building the Rick* (George Clausen, A.). Gallery VI.—386, *Roses and Crystal* (Ferdinand Sinet): somewhat roughly executed, with suggestions of Acacia and other plants. 451, *From the Riviera* (A. Miles Albert): a rather rough study of Anemones in a flat bowl. This picture is on the ground line, and one has to kneel to see it. Gallery VII.—512, "*All in the blue unclouded weather*" (Alfred Parsons, A.), is a masterpiece of art. In Gallery VIII. there is a good and lifelike portrait of the late Sir Michael Foster (the Hon. John Collier). It is unfortunate that the piece of chalk in Sir

fields; it is not suitable for Roses. No subjects demand a foundation of careful drawing more than plants. Gallery X.—*Oreads* (Annie L. Swynnerton): living statuary on a rock in the sea, with marine fishes. We were under the impression, till we were instructed by this picture, that the nymphs called oceanids, nereids, and naiads, belonged to the waters, and that oreads frequented mountainous dry land: but perhaps the names have been changed lately, as a jobbing country gardener once told me when I gently remonstrated with him as to his startling new nomenclature. Gallery XI.—*Wistaria* (David Murray, R.A.):

large, effective picture with Wistaria trained horizontally across the painting on the top of a wall; although the picture is named Wistaria, no attempt whatever has been made to draw either the blooms or foliage. 882, *The Nun's Garden* (Alfred East, A.). In this there is no garden whatever, but a mere patch of rough grass amongst tree stems; the name is perhaps satiric.

The Water-Colour Room must conclude our notice. 897, *A Bowl of Azaleas* (Edith Barrow): the Azaleas are white, and the picture is on the sky line, and beyond careful observation. 907, *Brier Roses* (Lucien Davies): a picture of pretty ladies by an admirable and well-known figure painter. The vegetable Briers are only property Briers. 916, *Primulas* (Edith Barrow): the flowers are those of *Primula sinensis*, the picture is on the sky line. 954, *Azaleas* (Edith Barrow): white Azaleas in an earthenware jug; very creditably drawn and coloured, but one has often seen these white Azaleas painted. 968, *Iris* (Lucien Davis): two pretty ladies by a pool, the vegetable "Iris" or Irids are shadowy and inconsequent. 973, *Lilies and Larkspur* (Alfred Parsons, A.): a most beautiful and carefully-executed garden view with Lilies, Larkspur, Roses, and Iris. 979, *Roses and Christmas Roses* (Woodhouse Stubbs): a vase with these blooms and winter Cherries, on the sky line. 987, *Rhododendrons*, by the same artist, appears—like the last—to be a good picture, but it is also on the sky line. 1,009, *Paeonies and Iris* (Alfred Parsons): this includes deep crimson-coloured Brier Roses, all drawn and painted with the highest skill. 1,017, *Spiraea gigantea*: by the same artist, including Iris and Water Lilies in a pool. The picture is in every way admirable, not only the flowers but the perspective of the foliage in the trees is surprisingly good; detailed in the foreground and less detailed in the more distant bushes. Nothing is more difficult in floral art than to paint flowers and leaves on a miniature scale. Mr. Parsons' work is almost miraculous. We called the attention of a friend—an exhibitor—in the water-colour room, to the fineness and beauty of Mr. Parsons' work, and he replied: "Oh, yes, but do you know how long he takes over these things? Why, he will spend a day in painting the sky of some of his larger subjects." Some artists don't want to study or expend time on pictures. There are several dismal failures in this class of drawing in the water-colour room. 1,036, *Pomona's Bounty* (Arthur Dudley): half-peeled and quartered Oranges, fine Apples, Cherries, and a punnet. 1,044, *Lobster, Trout and Mullet*, by the same artist: this includes a peeled Lemon and shrimps. Both these works are hung on the sky line, and, being placed so high, no proper opinion can be formed of their worth; from a distance they appear to be well done, but such subjects cloy on one from their painful iteration at exhibition after exhibition.

We now arrive at the final "screen." On this there are several old garden scenes, flower groups and landscapes, but none is distinguished, or calls for special notice. In the garden views it is not in some instances easy, if at all possible, to recognise the plants. There is the perennial *Harbinger of Spring*, 1,093, a Primrose plant on a bank (J. Jessop). 1,096, *The Parthenon: Moonrise* (A. J. Mavrogordato): this picture represents the Parthenon and other buildings as seen at night with the moon just rising; a great amount of experience and technical skill would be required to draw these buildings as they are seen by daylight. Why does not someone paint the interior of the Acropolis Museum as (not) seen at midnight, or the Parthenon room at the British Museum at night after the electric light has been switched off; either of these subjects would make a good "nocturne." *Your Artist.*

CORDYLINE AUSTRALIS IN NORFOLK.

We have had frequent opportunities of noting the hardiness of these plants in Devonshire, Cornwall, and various parts of Ireland, but we have not previously noted the occurrence of the plant in the Eastern Counties. A correspondent now favours us with a photograph of a so-called "Cabbage-Palm," which is, of course, neither a Cabbage nor a Palm (nor is it the true Cabbage-Palm) growing in a small garden in West Norfolk, about a mile from the sea. It was raised from seed sent from New Zealand and planted out in 1895. In the winter of that year it was killed to the ground, but recovered in the following spring till it has now attained the height of 15 feet. *C. australis* has sessile leaves, *C. Banksii* has long-stalked leaves, and there are other distinguishing features in the flower and inflorescence which are not available in this case.

FIG. 132.—CORDYLINE AUSTRALIS IN NORFOLK.

THE ROSARY.

ROSE CANKER.

THIS disease, which attacks all classes of the Rose, and causes eventually the death of the plant, is due to a fungus attacking the rind, which assumes patches of black colour. A Pomeranian gardener states in the *Gartenwelt* that his losses annually reach at the least 10 per cent., and under unfavourable conditions to 50 per cent., being much higher than the losses from any other disease. Usually the shoots of plants that are protected from frost by heaping soil over them, when taken out of the covering appear strong and of a green colour; but the affected shoots show the fungus on them as soon as exposed to sunshine; and it is advised to remove such shoots forthwith, for the disease soon spreads round them and infects the wood itself, hindering the flow of the sap through decay, and the plant may die in the course of the same summer. The fungus attacks

Roses whether heavily or lightly covered, or when not protected at all against frost, and in sunny or shady situations. Dwarf Roses of all varieties suffer less than standards, but mostly those with soft "water shoots," as, for example, Mme. Berard. In the gardening journals there have appeared for some years notices of canker patches on Roses, but it is not certain if these, in all cases, are caused by *Coniothyrium*. One correspondent of the journal mentioned writes that, so far, he had not noticed in his garden in Silesia the disease on *Rosa rugosa*, *R. canina*, or off *R. centifolia cristata*. Mostly, as he states, the fungus attacks the snags at the beginning. It is hoped that further research will throw light on the origin of the fungus, and the best means of combating its attacks. *F. M.*

KEW NOTES.

CYTISUS × BEANI.

ABOUT 14 years ago the introduction of *Cytisus* × *kewensis* caused great interest, for it was distinct from anything then in cultivation. It is of prostrate habit, bears creamy flowers in great profusion, and forms an excellent subject for the rock garden, or for covering bare ground. *Cytisus kewensis* has now been supplemented by another hybrid of somewhat similar habit, but with golden coloured flowers, and, as in the case of *C. kewensis*, *C. Beani* originated as a natural hybrid, the seed parent in both instances being the Alpine species *C. Ardoini*. It is considered the pollen in the older hybrid was from *C. albus*, but the male parent of *C. Beani*, judging from the general appearance of plant and flowers, is thought to be *C. purgans*. *C. Beani* is usually of prostrate habit, though it sometimes attains to a height of 6 or 8 inches, with the side branches arranged in a drooping manner. The appearance of the wood suggests *C. purgans* rather than the other species, as also do the leaves. The flowers are developed with the greatest freedom during the second and third weeks of May. They are similar in size to those of *C. purgans* and are of a beautiful golden shade. Like other plants of the same genus it gives little trouble to the cultivator if planted in a sunny position in a light loamy soil. It can be increased rapidly by means of cuttings inserted during the latter part of summer. The second name is in compliment to Mr. W. J. Bean, the Assistant Curator of the Royal Gardens, Kew. The plant may be seen in flower at Kew in the vicinity of the tea pavilion.

RHODODENDRON RACEMOSUM.

SELDOM has this pretty *Rhododendron* been seen in such perfection as at Kew early in May this season, the absence of frost during the past few weeks having allowed the flowers to open without injury. Messrs. Jas. Veitch and Sons, of Chelsea, introduced the plant 15 or 16 years since, and, similar to many newly introduced plants, it is of Asiatic origin, Western China being given as its home. In some respects it differs widely from other *Rhododendrons*, and it is of rather weak growth. Often the plant forms a compact mass of growths a foot or more high, but sometimes it assumes a more open habit of growth, and it then grows considerably higher. The tallest plants at Kew measure about 3 feet. The leaves are small, 1 to 1½ inches long, deep green above and glaucous beneath. The flowers are small, about ½ of an inch across, and the colour in some varieties is bright pink, but in others almost white. The flowers are produced in small, axillary clusters, and in some instances they are developed from almost every bud on growths 9 or 12 inches in length, the whole branch forming a raceme of flowers. At Kew several large masses of this *Rhododendron* are to be seen, notably behind the Palm house, in the neighbourhood of King William's Temple, and in the vicinity of the pagoda. *W. D.*

CULTURAL MEMORANDA.

ZAUSCHNERIA CALIFORNICA.

This pretty pink-flowered Pentstemon-like plant is not at all common in gardens, in spite of its having been introduced nearly three-quarters of a century ago. I have recollections of the plant in the gardens at Howick Hall, Northumberland, when my father was in charge in the period 1849-75. It was, although quite hardy in that part, not particularly showy as a plant for filling a bed, though doubtless effective enough on a rockery. It never seems to have occurred to anyone, then or there, that the beauty of the plant could be made more effective by cultivating it differently to ordinary herbaceous perennials. The plant has a weak, thin habit, and to show it off to advantage it needs, if planted wide apart, slight support from small flower sticks. A good method of treating the plant is to afford rich ordinary garden soil, and to plant it about 18 inches apart, and in April or early in May, as the side shoots develop in length, to layer them, fixing the shoots with pegs in the manner usual with Strawberry runners, leaving a few shoots erect. At the end of May the layers will have rooted, and they may be separated from the mother plants, and transplanted, each with its mass of roots and soil, to another bed, at from 6 to 8 inches apart. By the end of July the plants will be touching each other, forming a well-filled bed. Such plants begin to flower in the month of June, and continue till November. Another method is to keep stock plants for layering purposes, doing this as soon as the shoots have grown to a sufficient length. These early layers from potted stock plants should be potted-up singly, and planted out in May in beds or borders. It is a very charming plant when managed in the methods described. F. M.

The Week's Work.

THE KITCHEN GARDEN.

By WILLIAM H. HONESS, Gardener to C. COMBE, Esq., Cobham Park, Surrey.

Tomatos.—These should be nice, sturdy plants by this time, and in a condition to be stood out-of-doors in a position where they can be afforded protection at night. Such protection should be continued until nearly the end of the present month, when the plants may be put out into their permanent quarters. If the pots are becoming filled with roots, let the plants be given frequent waterings with liquid manure. If the first truss of fruit has set on each plant before it is planted out, ripe Tomatos will be available for consumption much earlier than otherwise, always provided that the plants are not allowed to become "hard" or stunted through the roots remaining for too long a time in small pots.

Broad Beans.—Plants raised from seeds sown in boxes early in the year, and that have been planted out after being well hardened as previously advised, will now be in full flower, and will soon require to have the tops pinched off them to prevent the black aphid from attacking them. This topping will also strengthen the plants, which the Beans will set earlier than if the plants were allowed to keep growing. Another batch might now be sown, of the Long Pod or Green Windsor types, and if Broad Beans are much in demand, further sowings might be made in the second week in June and at the end of that month. The crop is not always a success in hot, dry seasons if sown much later than the latter date. Sow also the white, or green-seeded varieties of Haricot and Butter Beans.

Turnips, &c.—Early sowings will now require thinning, and the work should be given immediate attention, as growth will now be unusually quick. If neglected in this matter, the plants will develop large leaves at the expense of the roots. Further sowings of the larger rooted and main crop varieties should now be made; these in larger quantities, as they are not so apt to "run." Parsnips and early Carrots should also be given attention in the way of thinning.

Seakale.—The beds that have furnished their supplies for this season, and have had the litter

and pots cleared away, should now be afforded a good dressing of dung and a sprinkling of salt, which should be dug in, filling up, as this work proceeds, all vacancies among the plants, with plants obtained from last year's seed bed.

Lettuce.—Early-sown batches will now be yielding good supplies. The Petite Noire and Gotte varieties of Cabbage Lettuce appear better adapted for culture in winter and early spring than any others I have tried. The former variety was exhausted some time ago, and the latter we commenced to cut at the commencement of the present month, and it is still yielding good "heads." [Some of these Lettuces received from Mr. Honess were excellent. The leaves were most succulent, and of very agreeable flavour.—Ed.] Frequent sowings of both Cabbage and Cos varieties should be made to keep up a supply that will satisfy the demand.

Cauliflowers that have been brought on in cold frames as successions to the earliest batches will now be quite large enough for planting out in their permanent quarters. The recent showery weather has been very suitable for carrying out this work. Fill up any vacancies that have occurred in previous plantings. Make another sowing for raising plants to furnish crops late in autumn and early in winter.

FRUITS UNDER GLASS.

By ALEXANDER KIRK, Gardener to J. THOMSON PATON, Esq., Norwood, Alloa, Clackmannanshire.

Successional Pines which were shifted into larger pots last month, will be rooting well into the new compost, and must receive special attention in the matter of watering, for on no account should the soil in the pots be allowed to become dry. The water applied to the roots should first be made tepid. Ventilation should be freely admitted during favourable weather, and everything done that is possible to keep the plants sturdy and prevent them making excessive growth. Damp the paths and the borders daily, for the atmosphere of the pits should be kept very humid. Maintain a bottom heat of 85° Fahr., and a night atmospheric temperature of 75°. The day temperature should range from 85° to 95°. The best time at which to close the pit in the afternoon is when the thermometer falls to 95°, but no rule-of-thumb method can be adopted in this respect, and the atmospheric conditions must be the guide in closing the structure. If properly managed, these Pines should furnish a supply early in winter, especially such varieties as Smooth Cayenne and White Jamaica. Plants on which the fruits are swelling should be encouraged into extra growth by a high temperature and a considerable amount of atmospheric moisture. If ventilation is given during the day, close the pits when the inside temperature is at 100°. Remove all but two suckers from each plant, also any "quills" that may appear on the fruiting stems, and supply the plants with weak liquid manure as often as they require moisture.

Figs.—As soon as the first crop of these fruits has been gathered, give the trees a good soaking with manure water, and afterwards place over the pots or borders a mulching of old stable manure. Syringe the trees freely, and keep the atmosphere in which they are growing moist. A suitable heat at night is 70° and 85° may be allowed by day. Close the ventilators early to conserve the natural sun-heat.

Peaches and Nectarines.—Air must be freely admitted to houses in which the fruits are beginning to colour: a little ventilation may also be applied by the top ventilators at night-time, providing the weather is mild. Train in the young growths, and push aside or remove altogether any leaves which may shade the fruit, for the latter requires the maximum amount of the sun's rays, in order to give them a rich, mellow colour. Keep the atmosphere of the house slightly humid throughout the day, but discontinue syringing. Test the borders, and give them a good watering if it is necessary. Such an application will be sufficient until the fruits are gathered. As soon as the fruits approach the ripening stage, secure them to the wires or shoots by putting two pieces of matting crossing at right angles over each fruit. This is preferable to allowing the fruits to drop into nets. Fruits of late varieties of Peaches and Nectarines which are now stoning will swell but little for the next few weeks. The trees should

not be excessively forced. The temperature of the late Peach-house should range from 75° to 80° by day, and 65° at night. Syringe the foliage freely, especially if any signs of red spider are apparent. Latest Peaches and Nectarines will now require their foreright shoots rubbed out and others thinned. Thin the fruit by degrees. Keep green fly in check by light fumigations with XL-All vaporising compound. At this stage of their growth give a good soaking with manure water whenever moisture is necessary, and place a layer of 2 inches of mulching material over the borders.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower to Sir TREVOR LAWRENCE, Bart., Burford, Surrey.

Cattleyas and Lælio-Cattleyas.—Such plants as *Cattleya labiata*, *C. Gaskelliana*, *C. Leopoldi*, *C. Percivalliana*, *C. amethystoglossa*, *C. Triana*, *Lælia elegans*, also many of the hybrid *Cattleyas* and *Lælio-Cattleyas* which have bloomed during the past few months, will now be making fresh growth, and where re-potting is necessary it should be attended to before the young growths commence to make new roots. These plants (especially if they are under the care of inexperienced men as regards watering) should not be overpotted, for if a large mass of soil is allowed to become very wet, it generally remains so for a long time, thus causing the roots to decay. The pots for these *Cattleyas*, &c., should be filled at least to about half of their depth with drainage material, such as broken crocks or well-dried peat rhizome. Over this place a thin layer of rough sphagnum-moss. Keep the base of each plant nearly on a level with the rim of the pot, and for the taller-growing varieties employ enough neat stakes to hold the plants firmly in their place. Make the compost firm about the roots, especially in the centre of the pot, employing of the best fibrous peat two-thirds and sphagnum-moss one-third, freely mixing with this some crocks broken small. Where it is difficult to obtain peat of good quality, the following materials may be used with equally good results: Polypodium fibre, *Osmunda* fibre (American peat), and sphagnum-moss in equal parts, chopping the whole up moderately fine, and mixing the materials thoroughly well together, adding sufficient small crocks to keep the whole porous. When re-potting large specimens use more of the fibrous materials and less of the moss, and it is especially desirable that in the case of large specimens the compost should be made very firm in the centre of the pot. Those plants which have become unhealthy from various causes, or have deteriorated in size, should be broken up, and each growing piece repotted into pots of moderate size. Where there are many old pseudo-bulbs behind the leading growth, most of them should be cut off, and it will be amply sufficient if two or three are allowed to remain to support the new growth. If it is desirable to increase the stock of any special variety, the severed pseudo-bulbs should be carefully labelled, and afterwards placed together in large pans or garden seed boxes, which should be provided with drainage and filled with a mixture of sphagnum-moss and crocks, allowing the base of each pseudo-bulb to rest upon the surface; keep them in an upright position, and treat them like imported plants. When new growths appear they may be re-potted. My practice then is to suspend them well up to the roof glass, and when suitable growth is made to stand them upon the stage with the established plants. For several weeks after these *Cattleyas*, &c., have been re-potted, the materials should be kept rather on the dry side, merely sprinkling the surface of the compost occasionally, and affording no more water than is absolutely necessary to keep the pseudo-bulbs and leaves fresh and plump. The young roots will gradually lengthen out and attach themselves to the sides of the pot. When this has occurred the supply of moisture at the root may be gradually increased. It is necessary for the beginner in Orchid culture to bear in mind that the plants should not be kept in a wet condition at the root for long together, nor should they be again watered until the roots have become properly dry. Until the plants are thoroughly re-established in the new compost they should be carefully shaded from direct sunshine.

PLANTS UNDER GLASS.

By J. G. WESTON, Gardener to H. J. KING, Esq.,
Eastwell Park, Kent.

Perennial Asters in pots.—In establishments where decorative flowering plants are required all through the season for the embellishment of the greenhouse or conservatory, a batch of these plants should be grown. The varieties have been greatly improved, and their colouring, habit, &c., differ considerably, so that many of them are adapted for this purpose. No time should be lost before potting some of the rooted offsets, selecting for the purpose strong single shoots farthest from the main stem. After potting, place the young plants in a cool frame for a few days, but as soon as they have recovered from their disturbance place them out-of-doors in a sunny position on a bed of ashes. When ready for re-potting, give them a liberal shift, using as a potting medium a mixture of turfy loam and well-decayed manure. Pot firmly. Copious supplies of water and a stimulant weekly must be afforded when the pots are filled with roots. Plants of single stems, well grown, develop beautiful heads of bloom, but if extra large plants are required, place three plants in a correspondingly larger pot.

Freelias and Nerines.—The amount of water afforded these plants must now be gradually reduced, and it must be withheld altogether when the foliage has died off. Place the pots in a frame close to the glass in full exposure to the sun, and admit plenty of outside air in order to aid the thorough ripening of the bulbs. In July shake the old soil from their roots and repot the Freelias, in order to have an early batch in flower at mid-winter. Freelias will not stand much forcing into flower, and should be allowed a long season of growth. Nerines succeed if left in the same pots till the bulbs are quite crowded.

Ornamental Grasses and Sedges.—*Scirpus riparius* (*Isoplepis gracilis*) is one of the most useful of the decorative grasses. Old plants that are untidy should be pulled to pieces, and the more vigorous portions from the outside of the plant be potted into small pots. Stand the pots in a structure having an intermediate temperature, and when they have started growth afresh, remove them to a cooler structure. Small, healthy plants should be potted into 4-inch pots, which are quite large enough for most purposes of decoration.

Cyperus alternifolius and C. a. variegatus.—When these plants are afforded too much shade, the leaves become thin and have little substance. *C. laxus* is suitable for growing in small pots. All the varieties of *Cyperus* are easily increased, either by division, by seeds, or from the old leaves placed in water, in which they quickly form roots. The plants should never be allowed to suffer from want of water at the roots, as their habits are somewhat those of an aquatic plant. Few subjects are more graceful for intermingling in groups of flowering plants than *Eulalia japonica* var. *variegata*. It is quite hardy, and adapts itself to cultivation in pots under almost any conditions. Its variegation is most marked when the plants are grown in warm conditions.

THE FLOWER GARDEN.

By A. C. BARTLETT, Gardener to Mrs. FORD, Pencarrow,
Cornwall.

Conifers.—An inspection of these trees should be frequently made during the growing season to see that the leader is uninjured, because the preservation of this is desirable in most species to maintain the symmetry of the specimen. If any have become too much damaged to be worth retaining, the nearest well-placed shoot should be tied up to a stake lashed to the main stem. If the top of the tree is more than a few feet from the ground, use a soft ligature, such as binder-cord, so that by the time the new leader is self-supporting, the tie will have rotted and fallen away. If tarred cord or wire were used in such cases there would be a danger of the ties being overlooked, and, as the trees swelled, the ties would cut into the bark, to the ultimate ruin of the specimen. Young trees of *Abies* and *Picea*, especially of the latter genus, often form twin leaders, which, if allowed to grow, not only destroy the outline of the tree, but later on form a lodgment for dead leaves and water, which soon induce decay in the fork, and a gale eventually splits the tree at this point.

Rhododendrons.—The early removal of the seed vessels is of great benefit to the bushes. Where *Rhododendrons* are grown in large quantities it is often impossible to relieve them all, but if a start is made upon the earliest blooming varieties, and the work continued at convenient intervals, much good may be done. It is imperative that the seed vessels should be removed from all young and recently-moved plants, and from those which are showing signs of exhaustion. These latter would derive great benefit from a mulching of partially decayed manure. Remove the point from any shoots which are making undue headway to the detriment of the shape of the bush. Remove the suckers which often spring up around the stems of grafted plants.

Auriculas and Primroses.—Seeds may now be thinly sown in pans or boxes of light, sandy soil. Barely cover the seeds and place the boxes in a cold frame. Although the florist's *Auricula* is comparatively tender and susceptible to damp, the "garden" forms are hardy, and have such a beautiful range of colour and form that they should be largely grown where spring flowers are in request.

Finks.—Just before the plants open their flowers they may be given a dressing of about 4 oz. to the square yard of some artificial manure, lightly hoeing the surface soil and giving a good watering should the weather be dry. If a portion of the bed be shaded during hot, dry weather, it will greatly prolong the season of these flowers. Cuttings may be taken of the newer varieties, and those of which the stock is short, but for renewing the main beds slips inserted out-of-doors in the autumn will root readily and give less trouble.

Dahlias.—For the lack of indoor accommodation we have to plant the tubers into their flowering beds and borders direct from the store. This will be done at once before the plants have made much growth. Should frosts appear likely to occur the plants will be lightly covered with mats and tiffany. I have found this plan more satisfactory than to first place the tubers in prepared beds under trees. Such plants make weak growths—due probably to the shade and draughts.

THE HARDY FRUIT GARDEN.

By J. MAYNE, Gardener to LORD CLINTON, Bicton,
East Devon.

Peaches.—In these gardens a plentiful crop of fruits has set and a good season is anticipated. Very few curled or blistered leaves have been noticed, although the nights during the latter part of April were cold, and frequent showers of hail and sleet fell whilst the trees were in blossom. It will now be safe to remove the protective material from the trees on ordinary walls, but if the trees are protected by glass coping in addition it will be well to allow the blinds to remain in position for another fortnight. Continue to remove at intervals superfluous shoots; also continue the disbudding of the fruits, retaining only those that are swelling freely. Defer the final thinning of the fruits for a few weeks; they can now be reduced to three fruits to each shoot, but finally one will be sufficient to remain if the fruits are developed on an average about 9 inches apart. In reducing the number of fruits the vigour of each tree must be considered; those that are making gross growths should carry more than weakly ones. There is no necessity for deferring the final thinning until after the fruits have stoned. Warmer days and nights may now be expected, when the trees should be syringed two or three times weekly. This will promote growth and help to ward off red spider. If mildew appears, syringe the foliage with Bentley's Specific No. 2, or dust them with flowers of sulphur, washing the latter off 24 hours after it has been applied.

Apricots.—It is some years since we had such good prospects of a large crop. At the final thinning 6 inches between each fruit will be sufficient on an average for the large fruiting varieties; smaller fruiting kinds may be given 2 inches less room apart. Pinch any shoots that will form spurs, at the fourth leaf, and nail or tie in shoots required for extension, or the wind may snap them off. Maggots will quickly ruin the points of the shoots if they are left undisturbed. See that no nail or eyelet is pressing against any of the fruits.

Strawberries.—The plants are sending up abundant flower spikes, which promises well for a plentiful crop. Plants specially grown for supplying runners must have all the flower spikes removed. Transplant seedling Alpine and perpetual bearing varieties before they become drawn. The protection of a garden frame will afford the seedlings a start, although if they have been fairly hardened by removal of the glass light daily, and by ventilation at night time, they should be sufficiently hardy to withstand exposure, especially if placed in a warm, sheltered corner.

PUBLIC PARKS AND GARDENS.

By W. W. PETTIGREW, Superintendent of the Parks and
Open Spaces in the City of Cardiff.

The mixed flower border.—In gardening, as in everything else influenced by human nature, fashion and taste vary from time to time. What appeals to and is popular with the public to-day is to-morrow abandoned and probably ridiculed as an absurdity. It often happens that the pendulum of fashion swings from the one extreme to the other, and this is evident in the case of gardening, for at one time the desire is, say, for informality, and at another for everything that is formal. The correct attitude for the gardener to adopt towards such fashions under all circumstances is to judiciously use, or combine, both extremes. The decision as to what constitutes the proper place for each style of treatment is always the point where the good taste and genius of the gardener is revealed. Upon the proper use or modification of formal and informal gardening depends the pleasure or otherwise that can be derived from any garden arrangement.

The ribbon border.—For what may be not incorrectly termed "spectacular" effects, a well-arranged ribbon border—a phase of formal gardening not by any means extinct—is difficult to surpass, and is much appreciated by the great majority of visitors to parks. During recent years these ribbon borders have, in many public pleasure grounds, been replaced by mixed borders composed of groups of varying sizes of distinct kinds of plants arranged irregularly—both in form and distance apart—throughout the whole length of the border. Although very much inferior to the ribbon border from the standpoint of brilliancy, the mixed border far excels it in interest and variety, both of colour and character. While the former kind of planting may be composed of merely half-a-dozen varieties of plants, the latter may easily include hundreds of different species and varieties. Hence in the one case, although the beholder is usually arrested at the first sight of such an arrangement as it burst upon his view, he soon ceases to be interested or delighted with it; but in the case of the mixed border, a continual source of delight is afforded from the time it comes into view until it is left behind. To obtain the best and most enduring effects from such a border it is necessary to have the groundwork of good, hardy perennials interspersed with choice and showy annuals and biennials. A border of this description, when extensive enough, can, by a judicious selection and distribution of the plants employed, be made a very attractive object for nearly six months out of the twelve. Many of the earlier-flowering annuals and biennials, such as Sweet Peas, Poppies, Canterbury Bells, &c., can be replaced when they have ceased to be effective by late-flowering plants such as *Celosias* and *Chrysanthemums*.

"Colour" borders.—Small, isolated borders are of added interest when converted into "colour" borders—that is, restricted to the culture of plants which are all of one distinctive colour. One such border may be devoted to yellow-flowering plants of different species, whilst another may be composed of blue, red or white. Such an arrangement may seem formal and monotonous in the extreme, but in reality such is not the case, as no two species used need be exactly the same in size and outline.

Labelling.—For the convenience and assistance of the public, all groups of plants in the mixed border should be distinctly, though not obtrusively, labelled. As showing the great interest taken in this type of plant arrangement compared with the ordinary formal bedding out, it is worthy of note that we have enquiries made by visitors from distant places every year regarding some flowers noticed in our borders.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Special Notice to Correspondents.—The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.

Illustrations.—The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but he cannot be responsible for loss or injury.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY, MAY 18—German Gardeners' Soc. meet.

MONDAY, MAY 20—Bank Holiday.

WEDNESDAY, MAY 22—

Devon County Agricultural Sh. at Bideford (2 days).
Roy. Bot. Soc. and Nat. Tulip Soc. Exh., Botanic Gardens, Regents Park.

FRIDAY, MAY 24—

Linnean Soc. Anniversary meet, 8 p.m.
Roy. Bot. Soc. meet.

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich—55°.

ACTUAL TEMPERATURES:—

LONDON.—Wednesday, May 15 (6 P.M.): Max. 61°; Min. 49°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—Thursday, May 16 (10 A.M.): Bar. 29.9; Temp. 55°; Weather—Cloudy.

PROVINCES.—Wednesday, May 15 (6 P.M.): Max. 57°, London and Ireland S.; Min. 48°, Ireland N.

SALES FOR THE ENSUING WEEK.

WEDNESDAY, THURSDAY, AND FRIDAY—

The "Clare Lawn" collection of about 4,500 Orchids, by order of the executors of the late Sir Frederick Wigan, at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 1.

A small book on this subject has been written by Dr. Richard Ewert*, director of the Plant-physiology Experiment Station at the Royal Pomological Institute, Proskau. We especially welcome its publication at the present time, when so much is heard of seedless Apples and so little is actually known of them. The term parthenocarp translated means "virgin fertility," and is equivalent to the English expression "seedless fruits."

Dr. Ewert emphasizes several points which are of importance in the production of seedless fruits. These are as follows:—

1. Before the flower-bud opens and insect fertilisation takes place, it is slightly pressed between the forefinger and thumb of the left hand and the stigma and upper portion of the style painted by means of a small brush dipped in a liquid to which the author gives the name "Kernlos." This liquid will prevent, by "mechanical and chemical action," the possibility of a pollen grain germinating on the stigma, but the nature of the liquid is not described in any way. The treatment should be carried out if possible on sunny days, or at least on days when

there is no rain. In one or two hours the "coating" dries on the style, which is thereby coloured a blackish red. This tint enables one to easily perceive whether a style has been efficiently painted or not. (We at first thought that the liquid used would be collodion, but this dries almost instantly and causes no discolouration. It would probably be worth while trying mercuric chloride or nitrate, which would kill the epidermal tissues and produce a similar stain, while it would not be washed off by rain.)

2. In order to prevent cross or self-fertilisation all the flowers must be treated in the manner described above. Those flowers which have opened before the treatment is commenced should be cut off, and also weakly ones and those injured by insects. The trees undergoing treatment should be watched and any subsequent flowers removed.

3. The trees best suited for this purpose are dwarf fruit trees, especially single cordons or pyramids, but standard trees may also be used. It is recommended that trees with not more than 300 flower-buds be chosen; 200 of the buds may at once be cut off, and the remaining ones treated.

4. Those trees should be selected which show a strong growth, and which have not borne in the previous year too much blossom or fruit.

5. It is desirable to leave untreated a tree of the same kind as those experimented with, in order to have the result of natural fertilization for comparison.

These five rules give the general principles to be observed. The author adds that the more carefully the stigma of the flowers is painted with the liquid the more perfect a seedless fruit will be obtained.

Dr. Ewert's preliminary experiments with varieties of Apple, Pear, and Cherry were carried out in a greenhouse, and did not prove very satisfactory; but it must be borne in mind that the trees were very small and did not grow under natural conditions.

The succeeding chapters deal fully with experiments on trees growing out-of-doors. We will give a brief outline of the experiments and the results obtained.

The following experiments (iv.) were made on the Apple known as "Cellini." (1) Cross-fertilisation was prevented by means of a gauze net; the stigmas were left untouched. Seventy-five per cent. of the fruits were seedless, 20 per cent. contained imperfectly developed seeds and 5 per cent. had perfect seeds. (2) All stigmas were painted with the liquid. Ninety-six per cent. of the fruits proved to be seedless. (3) The flowers were cross-fertilised, with the result that practically all fruits contained seeds. (4) On three branches fertilisation of the flowers was prevented. Only one seedless fruit was harvested. On the branches treated the flowers quickly faded and no fruits developed. All the other branches bore seed-containing fruits. This experiment shows that if the flowers of only a part of a tree are sterilised, they are unable to produce seedless fruits for the reason that they are outgrown by the others. These experiments also show that "virgin-fertility" exists naturally, and they tend to prove what the American observer, Waite, correctly said, that the property is co-existent with self-fertility.

A series of analogous experiments were carried out with the Pear *Beurré Clairgeau*.

The first experiment, which was similar to the first made with Cellini Apple resulted in the production of 100 per cent. seedless fruits. The second experiment gave a crop of 85 per cent. seedless fruits, and so on. From the experiments with *Beurré Clairgeau* it was also shown that parthenocarp and self-fertility are identical qualities.

In endeavouring to ascertain the effects obtainable in other varieties the following Apples were subjected to experiment: *Charlamowsky*, *Winter Golden Pearmain*, *Baumann's Reinette*, and *Kaiser Alexander*. Only *Charlamowsky* and *Winter Golden Pearmain*, however, showed any tendency towards parthenocarp.

In addition, other varieties of Pears were made the subjects of experiment. *Gute Louise von Avranches* had 99 flowers treated, and 92 fruits were obtained, of which 87.3 per cent. of the fruits were seedless.

The author summarises his experiments by relating the following results:—

1. Soon after flowering the following experimental trees dropped their fruits:—*Apples*: *Baumann's Reinette* and *Kaiser Alexander*. *Pears*: *Bergamotte Esperen*, *William's Bon Chrétien*.

2. Inclination to parthenocarp present in these varieties, but the fruits fall off on attaining the size of a nut. *Pears*: *Pastorenbirne*, *Zepherine Grégoire*.

3. The seedless fruits remain singularly small. *Apple*: *Winter Golden Pearmain*.

4. The seedless fruits attained normal size, though differing in shape from them. *Apples*: *Charlamowsky*, *Cellini*. *Pears*: *Clairgeau*, *Gute Louise von Avranches*, *Holzfarbige Butterbirne*, *Nina*, *König Karls von Württemberg*, *Abbé Fêter* (in which variety cross-fertilization only was prevented).

Dr. Ewert considers in the concluding chapters the practical value of growing seedless fruits. He states that, though it is perfectly true that seedless Apples and Pears can be raised of the same size and quality as the others, yet the hard, horny cores, especially in Apples, still remain. He expresses the hope, however, that since the core exists only for the protection of the seeds, the disappearance of the seeds will eventually be followed by the disappearance of the core, in accordance with the well-known law of nature that organs or parts which have been rendered superfluous will in time vanish. That this is quite possible is shown by the case of the seedless currant, where the hard seed coats are entirely changed into soft tissue.

Dr. Ewert is of the opinion that a perfectly seedless and coreless Pear would fetch a sufficiently high price in the market to compensate for its expensive and artificial culture.

He suggests that the discovery of parthenocarp is also worthy of consideration from another point of view. He refers to the frequent disappointing results of the fruit crop (even though the trees may have had plenty of flowers) caused, perhaps, by the absence of bees at the time of flowering, or by unsuitable conditions of the weather. In brief, it is advisable to plant such trees that are capable of producing seedless fruits, for these, the author states, will furnish fruit even when, for some reason or other, cross-fertilization has not taken place.

* *Die Parthenocarpie oder Jungfernfruchtbarkeit der Obstbäume*, by Dr. Richard Ewert. Published by Messrs. Paul Parey, Berlin (1907).

Supplement to the "Gardeners' Chronicle."

VIEW IN THE CENTRE OF THE PALM HOUSE AT KEW,
SHOWING THE SLATE-ENCLOSED BEDS.

Temple Press Ltd., Printers, 7-15, Rosebery Avenue, London, E.C.

OUR SUPPLEMENTARY ILLUSTRATION represents a view in the Palm House at Kew, and shows some of the centre, slate-enclosed beds that are furnished with a variety of tropical plants, chiefly of ornamental-leaved species. The photograph was taken near the middle of the glasshouse, above which point the glass roof is 66 feet distant, enabling tall Palms to show their full beauty. The staircase seen in the background of the picture leads to a gallery extending around the centre portion of the structure, and from this platform can be obtained an excellent view of the tops of tall Palms, Bamboos, Dracenas, Pandanus, and similar plants, intermingled with climbers, so that the scene suggests the looking down upon some tropical forest. The gratings cover a part of the hot-water system, and they form a considerable part of the floor all over the house. These gratings—and the remaining parts of the walks are flooded several times each day, the water running down amongst the pipes, to be evaporated again, thus producing a sufficiency of atmospheric moisture. The Palm House is really a huge stove, and it requires the services of two men as stokers continually, the boilers being situated beneath the structure. The expanse of glass is so considerable that on cold days the temperature on the windward side of the building is often several degrees lower than on the opposite side. Nearly four miles of 4-inch piping are carried over the entire ground area of the building. Originally the architect arranged a series of underground flues communicating with a smoke-tower, an Ivy-covered structure that appears like a water-tower, situated at about 500 feet distant from the Palm House. This arrangement has been superseded by flues from the furnaces carried through the building and above the roof.

FLOWERS IN SEASON.—From Mr. JOHN CROOK, Forde Abbey Gardens, Chard, we have received a box of a very fine strain of Polyanthus in bright and varied colours. Mr. CROOK writes: "I have been working for the improvement of this strain of Polyanthus for many years. I displayed a large non-competitive exhibit of these flowers at the National Auricula Society's Show on April 30, when they were much admired. I am leaving Forde Abbey in the autumn, after which I intend to grow these plants, and sell the seeds of same, &c."

THE ROYAL GARDENERS' ORPHAN FUND: ANNUAL FESTIVAL DINNER.—We desire to remind our readers that the annual festival dinner of this fund will take place on Thursday next, the 23rd inst., at De Keyser's Royal Hotel. The Right Honourable the LORD MAYOR (Sir WILLIAM P. TRELOAR), will preside. Subscriptions or donations will be gladly received by the following gentlemen, who have kindly consented to act as stewards on this occasion:—W. Alderson, Hersham Road, Walton-on-Thames; James T. Anderson, 135, Commercial Street, E.; John Assbee, Market Office, Covent Garden, W.C.; W. Y. Baker, Thames Bank Iron Co., Upper Ground Street, S.E.; George H. Barr, 11, 12, 13, King Street, W.C.; W. Bates, Cross Deep, Twickenham; Harry Bird, C.C., The Drive, Chingford; William Bull, 536, King's Road, Chelsea, S.W.; G. Bunyard, V.M.H., The Royal Nurseries, Maidstone; G. Caselton, Garden Superintendent, Crystal Palace, S.E.; W. H. Cooke, Kingston Hall Gardens, Derby; Geo. H. Cuthbert, The Nurseries, Southgate, N.; W. H. Cutbush, The Nurseries, Barnet, Herts; C. Dixon, Holland House Gardens, Kensington, W.; W. A. Garaway, Durdham Down Nurseries, Clifton, Bristol; W. Howe, Park Hill Gardens, Streatham Common, S.W.; D. Ingamells, 27, Catherine Street, Covent Garden, W.C.; James L. Kinnell, 45A, Southwark Street, S.E.; John Lyne, Fox-

bury Gardens, Chislehurst; H. B. May, Dyson's Lane Nursery, Upper Edmonton; J. F. McLeod, Dover House Gardens, Roehampton, S.W.; J. W. Moorman, Superintendent, Victoria Park, E.; T. A. Morris, 67-68, Cheapside, E.C.; Whitpain Nutting, 106, Southwark Street, S.E.; R. Hooper Pearson, *Gardeners' Chronicle* office and 40, Brocklebank Road, Wandsworth, S.W.; W. Poupart, Marsh Farm, Twickenham; W. Roupell, Harvey Lodge, Roupell Park, S.W.; G. Reynolds, Gunnersbury Park Gardens, Acton, W.; T. W. Sanders, 124, Embleton Road, Lewisham, S.E.; Edward Sherwood, 152, Houndsditch, E.; David W. Thomson, 113, George Street, Edinburgh; W. P. Thomson, 25, Bollo Lane, Chiswick, W.; Harry J. Veitch, V.M.H., Royal Exotic Nursery, Chelsea, S.W.; P. C. M. Veitch, J. P., High Street, Exeter; J. H. Witty, St. James's Villa, Swain's Lane, Highgate, N.; and the secretary, Mr. Brian Wynne, 30, Wellington Street, W.C. Of all appeals that are made to the benevolence of gardeners and others interested in horticulture, none should be more effective than this one which has for its object the care and sustenance of necessitous children whose fathers were gardeners, and who, through early decease or other reasonable causes, have left no provision for their children.

KEW GUILD DINNER.—We are requested to remind our readers who are Old Kewites that the annual dinner will take place at the Holborn Restaurant on the 27th inst., at 7.30 p.m., and that the secretary, Mr. W. N. WINN, would be glad to hear before the 20th from all who intend to be present. Mr. GEORGE MASSEE will preside, and amongst colonial and Indian members expected to be present are Messrs. J. ANDERSON (Gold Coast), S. ARDEN (Singapore), K. G. BURBRIDGE (Gold Coast), J. BURTT-DAVY (Pretoria), J. M. PURVES (British Central Africa), T. R. SIM (Natal), and J. STOCKS (Portuguese East Africa).

UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.—The monthly committee meeting was held at the Royal Horticultural Hall, Vincent Square, Westminster, on Monday evening last, Mr. CHARLES H. CURTIS presiding. Nine new members were elected and one nominated. The amount paid for sickness since the last meeting was £52. A grant of £5 from the Benevolent Fund was made to the widow of a late member, who died after a long illness.

AGRICULTURAL EDUCATION.—The Departmental Committee, of which Lord REAY is chairman, held meetings on the 7th, 8th, and 9th inst. Mr. A. D. HALL, Director of the Rothamsted Experimental Station, Harpenden, Sir C. T. D. ACLAND, Bart. (nominated by the Bath and West and Southern Counties Society), and representatives of the Midland Agricultural and Dairy College, Kingston, Derby, the Agricultural and Horticultural College, Uckfield, the British Dairy Institute, Reading and Leeds University, attended and gave evidence.

THE LORD MAYOR'S CRIPPLES' FUND.—A publication called *Crutches to Help Cripple Children* is to be issued on June 5th, on behalf of the Lord Mayor's Cripples' Fund. Sir DOUGLAS STRAIGHT is acting as Hon. Editor for the Literary Section, and Sir JAMES D. LINTON, R.I., H.R.M.S., is responsible for the Art Section. We are informed by Sir WILLIAM P. TRELOAR that a large number of well-known authors and artists have kindly given their services, and the result will be a literary and art production in every way unique. The entire profits on this book are to be devoted to the fund he is raising for the provision of homes to treat the tuberculous cripples of the poor, and for which £60,000 is required. The publishers are Messrs. BEMROSE & SONS, LTD.

DESTRUCTIVE INSECTS AND PESTS BILL.—This Bill, which has been already referred to in these columns, and which will give increased powers to the Board of Agriculture in the matter of preventing the spread of insect pests and fungus diseases, was read for the third time in the House of Lords on Monday last, May 13.

THE SEASON OF LILAC.—The Lilacs are now at their best, and in most districts the bushes are blooming with unusual freedom. From several quarters we are informed that there was never a better display than at the present time.

MAGNEY OR SIBAL HEMP.—The cultivation of Magney in the Philippine Islands is, as we learn from the *Tropical Agriculturist*, at the present time attracting widespread attention. In those provinces from which Magney has been exported for a number of years, larger areas are now being planted. In other sections where this plant has been either unknown or unnoticed, it is now being introduced. In order to supply the many requests for information in regard to its cultivation, the Philippine Bureau of Agriculture supply, in as brief and simple form as possible, a circular printed in English, Spanish, and other languages. It takes the form of 16 questions and answers.

HOLLY LODGE, HIGHGATE.—In the issue of *The Times*, published on the 11th inst., a correspondent of that paper announced that: "It has been decided to dispose of the Holly Lodge estate at Highgate, which was for many years the summer home of the late Lady BURDETT-COURTS. The estate, which extends to over 50 acres, is to come into the market during the coming season."

LANDSCAPE GARDENING.—Mr. B. T. BATSFORD will publish in a few days a new and enlarged edition of Mr. THOMAS H. MAWSON'S *The Art and Craft of Garden Making*, the last edition of which was issued in 1901. It is announced that the present edition will contain numerous fresh illustrations and schemes of gardens.

MAY-FLOWERING TULIPS.—An excellent display of May-flowering Tulips is now in bloom at our Surbiton nurseries, write Messrs. BARR & SONS. The collection covers some acres of ground, and we have rarely, if ever, had such a grand show.

COCOANUT PLANTING.—This is a remunerative and safe investment in the tropics, better even, perhaps, than that in rubber, there being an enormous demand for cocoanut oil, copra, and desiccated cocoanut in Europe and America, which cannot be met. The literature on the subject is not extensive; but there is one book, the *Cocoanut Planters' Manual*, by JOHN FERGUSON, price 4 rupees, published at the office of the *Tropical Agriculturist*, Colombo, Ceylon, which affords all that the planter requires to know about cultural and cognate matters.

THE IMPERIAL BIOLOGICAL INSTITUTE AT DAHLEM.—Professor Dr. WORTMANN, Director of the Royal College for Fruit Culture and General Horticulture, Geisenheim, has been appointed director of the Biological department at Dahlem in the place of the late Privy Councillor ADERHOLD.

THE OLD BOTANICAL GARDEN, BERLIN.—This area of 58,000 quadrate metres has been acquired by the city authorities for the sum of 2,000,000 marks, and was taken over on April 1 last.

SMOKE AND FROST-PROOF CONIFERS.—In the various Berlin parks, a number of species of Conifers have been under the observation of Hrn. FINTELMANN, Royal Horticultural Director for a number of years. Of those planted in 1871, many have been destroyed by the products of combustion in the factories erected since that date, and in the locomotives of the Stettin railway, or they have been so reduced in vigour as to have been killed in hard winters. Those which have best withstood these unfavourable conditions are *Abies numidica*, *A. balsamea*, and it is particularly worthy of notice that a plant of *Araucaria imbricata*, left out of doors during the severe winter of the present year, was quite unharmed. More observations, by several of the landscape gardeners present at a meeting of the Society of German Landscapists on April 15 last, will be communicated at future meetings of the society.

DRESDEN.—The International Horticultural Exhibition at Dresden, writes a correspondent, "was an exhibition showing all the art the horticulturist can put into his work. The various competitions, as, for instance, decorated church altars, decorated ladies' boudoirs, gave plenty of opportunity for the genuine artist to display his talents. An idealistic imitation of a forest with tropical plants and Orchids as growing in their natural habitat was even better than one would expect in a country where things are done so thoroughly as in Germany. This forest occupied a space of about 3,000 square feet, and was made to look larger by the addition of a large and specially painted picture to form a perspective in the distance. The exhibition ground was exactly suited for its purpose. A large proportion of the plant exhibits were representative of Dresden's specialities—*Azaleas*, *Rhododendrons*, *Camellias*, &c.—but excepting these plants one saw no superiority over those of our own cultivation. There were only two English firms represented, Messrs. HUGH LOW & Co., who were awarded a special prize for an exhibit of perpetual-flowering Carnations, amongst which such new varieties as *White Perfection* (undoubtedly the best of all whites), *Britannia* (the Gold Medal scarlet), and *Mrs. Burnett* (salmon-pink) figured prominently. Messrs. CHARLES-WORTH & Co., of Bradford, Yorkshire, put up an excellent group of Orchids. The exhibition was opened on Saturday, May 4, by the King of Saxony, but the attendance on the first day was far behind that at a similar show in this country, although of course the crowd on the Sunday was considerable."

BORING PESTS ON FRUIT TREES.—In many parts of the country fruit-trees may be noted in which here and there branches have died without apparent cause. A close examination would show small holes in these dead or dying stems and branches, which form the entrances of those treacherous pests, the various species of the genus *Scolytus* and *Bostrichus*. If the rind of the injured branches, &c., be removed, numerous galleries or borings will be found just beneath the rind and in the sapwood, and a number of white grubs in them; and, should the search be made in the months of May, June, and July, fully developed insects. From the entrance hole in the rind of the youngest sapwood a simple gallery is formed by most of the species of *Scolytus* and from this on both sides the so-called larva-borings extend. The female lays her eggs at the sides of the borings to the number of 20, and the footless larvæ increase the width of the borings, and appear in the following year between April and July as perfect insects on the surface in search of a place in which to settle, where the circle of development begins anew. The insects attack healthy as also unhealthy trees. The following three species are common at times, viz., *Scolytus*

pruni, which chiefly infests the sapwood of Plums, Apples, Pears, and Cherries, is black, the feelers and legs brownish red, and the wing cases brown. The hinder part is raised slanting-wise, and appears as if shortened. The length of the creature is about 3.5mm. *S. rugulosus* is about half as large, and is less shining; the colour in general is black, the points of the wing cases being of a lighter tint. It is found on all kinds of fruit-trees.—*Bostrichus dispar*: The size of the sexes differs, the female being 3.5 mm., and the male 2 mm. long; colour, pitch-brown and covered with fine hairs. The males are always the fewer in number. Contrary to the before-mentioned species, it is the female which perforates the stem, and the progeny which are raised from the eggs that she lays in the hole that carry on the borings lengthwise of the stem. The first thing to do for a successful fight with these insects is to remove the whole of the infested and sickly trees and branches, and remains

MacDougal, Director.—*Hybridisation of Wild Plants* by D. T. MacDougal.—U.S. Department of Agriculture. *Leguminous Crops for Green Manuring*, by C. V. Piper.—University of California. Agricultural Experiment Station. *Report of the Plant Pathologist*, to July 1, 1906. By Ralph E. Smith. A chronicle of much useful work.—*The House Beautiful*. A Chicago magazine with many hints upon house decoration, and a section devoted to gardening.—*Radix*. Vol. IV. Fascicolo I. of an entomological magazine published in Florence.—*The Botanical Magazine*, Tokyo, February, among other interesting articles contains a paper on Taiwan and its affinity to other genera.—*Agricultural News* (Barrados), April 6. Full of useful notes on tropical and other crops.—*Bulletin of the American Association of Park Superintendents*. The experiences of this association are worth notice by similar officials in other districts.—*London Botanic Gardens*. By Pierre Perrédès. This contains illustrated accounts of the history of Kew, the R.H.S. Gardens, the Botanic Society's Gardens, and the Chelsea Physic Garden.

FRUIT CROPS AND FROST.

So serious have been the losses sustained by fruit-growers in the Vale of Evesham in some

FIG. 133.—PROTECTION FROM FROST.
(Smudge-pots in an Evesham Orchard.)

of trees, as it is precisely these that offer points from which healthy trees can be attacked. It further helps matters if the soil be afforded a dressing of suitable manure, more particularly phosphoric acid, lime, and potash, for the purpose of imparting vigour to the trees, as neglected trees are usually the first to be attacked. On the appearance of *Scolytus pruni* in the spring manure water should be applied, so as to a certain extent smother the larvæ in the abounding sap. Trees that are greatly infested should in early spring be felled, cut up into small pieces, and burned, so as to prevent any further increase in the woodstack or dépôt. Further, all slightly attacked trees should be dressed with freshly-slaked lime-wash, and this dressing should be repeated if traces of the insects be visible. It is only by a timely carrying-out of the above means that the fruit cultivator can avert great injury to his trees.

Publications Received.—*Annual Report of the Agricultural Experiment Stations of the Louisiana State University*. By W. R. Dodson, Director.—From the U.S. Department of Agriculture.—*Method of Eradicating Johnson Grass*, by J. S. Cates and W. J. Spillman.—*Report of the Department of Botanical Research*, Washington, by D. T.

past seasons by reason of the destruction of crops by the late spring frosts, that attempts are now being made to accomplish the apparently impossible task of abolishing the frosts in the plantations. Smother fires of rubbish or other material have been tried, but without much success, and experiments have also been made with preparations known as foyers, as used in the grape-growing districts of France, but these proved to be too expensive for commercial use. A large measure of success has, however, been achieved with oil-pots, or smudge-pots, as they are sometimes called. These are tin cans, 9in. high, tapering upwards, with two rows of holes near the top; each pot holds a gallon of creosote, to which some naphthalene salts and a little water are added. The pots containing the creosote, with a whisp of hay in the mouth to aid ignition, are placed about the plantations at the rate of 40 to the acre; stakes or some other indicators are fixed at the ends of the rows of pots, so that they may be easily located in the dark. Electric alarm thermometers are fixed up in the plantations, which ring bells in the foremen's houses when the mercury falls to 32° Fahr. The pots are afterwards lighted by means of a torch, and

they will burn without recharging for about three hours, which is long enough in the case of ordinary spring frosts. It is usually found necessary to light them about half-past two or three o'clock in the morning. They have a two-fold effect. Not only do they raise the temperature very considerably, but they create a pall of dense smoke, which hangs like a heavy blanket some 8 or 12 feet from the ground, and envelops the trees. The principal object of the smoke is to prevent the damaging of the embryo fruits by the frost, rather than to keep the sun's rays from completing any damage already effected. Experiments were tried last year on a somewhat large scale by Mr. Martin, at Todington, and by Mr. Geoffrey Hooper, of the Croft Fruit Farm, Pershore; and the results were very satisfactory. Allowing five shillings per acre for labour, the cost should not exceed 20s. per acre per night. The illustration is from a photograph taken by Mr. Hooper's kind permission in his plantations at Pershore. W.

exterior of the mansion are some fine specimens of *Magnolia grandiflora*. These are crowded with flower-buds.

In front of the windows are several large flower-beds, which at the time of our visit early in the present month were filled with bulbous flowers. Some very fine pyramidal Yews are planted at corners where the paths intersect, and a number of choice statues in marble are scattered about these flower-beds. There are also several handsome vases which are furnished throughout the year was seasonable subjects. Tulips, Hyacinths, Anemones, with edgings of various *Ericas* adorned these beds. One was filled with red, white, and blue-coloured Hyacinths, and intermingled are later-flowering Tulips, that were just showing their flower-buds. Another was gay with the yellow Tulip *Chrysolora*, around which were scarlet Anemones, edged with Golden Yews trained very dwarf, and an outer band of *Erica mediterranea*. Bulbs have been planted in great numbers, and many are natural-

is an object of great beauty! In summer the waters are bright with Water-Lilies, including the beautiful *Nymphæa atro-purpurea* which Lord Hillingdon showed in such fine condition at the meeting of the Royal Horticultural Society on July 31, 1906, and a flower of which formed the subject of our supplementary illustration in the issue for February 16, 1907. The whole of this water-garden is surrounded with a dwarf wall, surmounted by an appropriate design in stone work, and facing the pool is a luxurious summer-house with a facade of copper ornamented in bas-relief with the Hillingdon arms and appropriate scroll work. A large stone figure of Neptune reclining occupies the middle of the lake. Leaving the water-garden on the left, a new part of the garden is entered, and this is carpeted with fine turf, in which are cut several large beds. These are newly planted, and all the occupants are in vigorous growth. One has an assortment of arborescent Ivies, amongst which are planted Spanish Iris; another is filled

FIG. 134.—A WATER-GARDEN AT HILLINGDON COURT, UXBRIDGE, THE RESIDENCE OF LORD HILLINGDON.

HILLINGDON COURT, MIDDLESEX.

THERE are many beautiful spots in the county of Middlesex, especially around the vicinity of Harrow, and between this town and the important borough of Uxbridge is situated Hillingdon Court, the country seat of Lord Hillingdon.

It is best reached from town by the Metropolitan Railway to Uxbridge, and across a public path through a picturesque park. Hillingdon Court is a comparatively modern edifice; it was built by the grandfather of the present owner, but the beautiful gardens and grounds as they now exist have been formed by the grandson, whose gardener, Mr. A. R. Allan, has carried out the work with admirable skill. The gardens are surrounded by park land that stretches almost as far as Harrow, and each year some new feature is added to the gardens and grounds, the necessary land being readily available. Indeed, the place may be said to be a garden in the making, and will undoubtedly rank in the future with the finest in the county. The residence is a square-built structure with a wing of considerable size attached, and to this latter part a big conservatory. Trained up the

used in the grass and beneath trees. Looking in the direction of Harrow is seen a broad terrace with fountains and a water-garden (fig. 134). One first encounters a broad expanse of grass, in which has been cut a large tri-lobate shaped bed, with the apex towards the mansion. This has an edging of box, and the base of the leaf is planted with golden tree Ivies. The whole is designed on a bold scale, and was filled with Tulips, in the centre *Chrysolora*, and the outer bays with Cottage Maid and the red Prince of Austria. A little beyond is a large water-basin with a fountain in its centre, and around are a number of smaller flower-beds. The whole of this grass, with its enclosed beds and fountain, is edged with a stone kerb, and against the relief of the admirably-kept gravel walks the design stands prominent.

Still further in the direction of Harrow, which is seen through a vista of trees in the distance, a flight of large circular stone steps leads to another broad expanse, which encloses a water-garden (fig. 134). The basin measures about 100 feet in its broadest part, and is about half this distance in width. The front from the steps is not broken, but on the other three sides half-circular bays are included, and with fountains in the centre and at either wing, the whole

with the golden *Cupressus macrocarpa*, and against a background of Scots Fir is one filled with Azaleas, and edged with *Ericas*. Hereabouts in the turf are innumerable Daffodils, Tulips, and other spring flowers, appearing in their natural setting more beautiful even than those in the symmetrical flower-beds. A weeping Elm; *Narcissus Horsfieldii* about its base, is deserving of mention.

Walks have been formed in the grass by close mowing, and some lead past shrubberies, which are filled with the choicest subjects. The shrubs at Hillingdon Court are a fine show, and many thousands of all kinds have been planted by Mr. Allan during his term of office, and he has made the most of the opportunities afforded by the natural features of the place. Wherever a band of trees exist, the shrubberies and walks have been so designed that the trees serve either as a background, to break the continuity and formality, or terminate the planting. A newly-planted shrubbery was gay with *Cytisus præcox*, *Pyrus Malus floribunda*, Lilacs, Rosemary, *Exocorda grandiflora*, *Andromeda floribunda*, *Cerasus pseudo-cerasus*, *Ericas*, *Phillyreas*, double-flowered Gorse, and many other subjects in flower. At the back of this

shrubbery is a long walk, with herbaceous borders, a part of these is planted with blue flowering plants, and the other part with those having red flowers.

This spot is the present limit of the gardens proper, and meets the park which stretches away for 200 acres in the direction of Harrow-on-the-Hill. Roses on pillars, and others standard and bush-trained, with Honeysuckles at intervals, are planted in profusion along this walk, which must be a very attractive feature when the whole of the plants are in flower. A path beneath a cluster of Pine trees that is carpeted with Irises leads to an open expanse of lawn bespangled with hosts of Daffodils and Tulips. A large Rose-bed, planted with 500 bulbs of Narcissus Emperor, was a grand scene. Roses are planted abundantly in these gardens—in large beds by themselves, by walks, in borders and shrubberies, and they have also a separate quarter to themselves, the site of an old sunken Dutch garden. The big beds have tall pillar plants in their centres, and there are also arches adorned with climbing varieties.

A small Pinetum has been newly formed, and planted with *Pinus tuberculata*, *P. pinea*, *P. fremontiana*, *P. muricata* (syn. *Murryanæ*), *P. sabiniana*, *P. ayacahuite*, *P. parviflora*, *P. conorta*, *P. muricata*, *P. cembra*, *P. excelsa*, *P. flexilis*, *P. pyrenaica*, and *P. jeffreyi*. There are also some young plants of the golden Cedar.

A Yew-enclosed garden, with a sunken tennis lawn, having bright patches of bulbous flowers at either corner, and a special quarter planted for autumnal tints are other interesting features. Almost everywhere there are bright patches of bulbous flowers, and seen on a glorious spring day they were doubly enchanting. Every quarter of the garden is maintained in an admirable manner; the tidy aspect of the walks, verges, lawns, flower-beds, and borders being excellent. The glass-houses, fruit, and kitchen gardens are maintained in the same state of efficiency. The gardener is a son of Mr. W. Allan, who has been head gardener at Gunton Park for so many years.

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

GARDENERS IN NEW ZEALAND.—The note, p. 308, on emigration to New Zealand, reminded me of a letter, dated January 29, 1907, received from Mr. W. Jones, Exeter Nurseries, Papanui Road, Christchurch. I enclose a copy of a portion of his letter which has reference to the prospects for gardeners in New Zealand, which is in direct opposition to the statement of Mr. Harding published last week. "Horticulture is going ahead in New Zealand by leaps and bounds. Our greatest trouble is to get competent gardeners; these are too scarce unfortunately. Those that come out from England, with very few exceptions, are poor hands." *Thomas Peed.*

TO PRUNE OR NOT TO PRUNE.—Mr. J. Simpson, on p. 304, raises four or five different issues, and in his note I think he has failed to do justice to his reputation as a cultivator and observer. I have always been an advocate of judicious pruning of fruit trees; and the trees he saw in the County Experimental Garden, Droitwich, at the beginning of 1900, had all, with the exception of 37, been annually pruned. On that occasion Mr. Simpson very kindly expressed his approval of the fruitful condition of the trees generally; and well do I remember the temptation I then and subsequently had to discontinue pruning all these trees. But glad am I that I resisted the desire to secure the maximum amount of fruits from these trees when young. Most of them were planted in 1896, and are now admired by all who see them, and I am sorry that Mr. Simpson did not call when he was in this locality recently, for had he then seen them it is very probable certain sentences in his note would not have been written. The 37 unpruned trees above mentioned

consist of Apples, Pears, Plums and Red Currants, and in no year or instance has the fruit from these trees been so good in quality as that from pruned trees grown in other respects under equal conditions. The results quoted in the *Gardeners' Chronicle*, p. 249, are as reliable as results from another source, even though they were made, noted, corrected and published by Mr. Simpson himself. With regard to the general practice or non-practice of pruning fruit trees in Worcestershire, I have only to say that the amount of pruning performed in this county by growers annually increases; to suggest that the facts are otherwise is an injustice to the intelligence of the large fruit-growers and market-gardeners of the county, who, as cultivators, are surpassed by none in the country. Within about 2,000 yards of my writing-table are two separate fruit orchards, each for many years managed by an intelligent man. Each of these managers annually endeavours to approximate his pruning to the standard practised in the Experimental Gardens, and I believe that both farms are profitable. As showing whether pruning is common in the locality or not, I may say that the applications made to these Experimental Gardens for instruction in pruning are more than we can attend to. *James Udale, Experimental Garden, Droitwich.*

HARDINESS OF CALLA ÆTHIOPICA.—Recently when looking over the very interesting gardens and grounds at Byram Park in this county, I was somewhat surprised to see some strong growing plants of *Calla æthiopica* on the margin of the lake. Mr. Taylor, the gardener, informed me they were planted when in a dormant condition last autumn. Some few years ago when preparing baskets for the reception of some of the choicer kinds of Water Lilies for planting in this lake, a quantity of old potting soil in which these Callas had been grown was used. The following season a stout plant of *Calla* came up amongst one of the Water Lilies, and in due time produced a good-sized flower. It was this fact which induced Mr. Taylor to make a planting of this *Calla* in the open. They are planted in about 3 feet depth of water: the lake has, during the past winter, been frozen over. *Henry J. Clayton, Wharfe Bank Cottage, Ullestree, near York.*

VENTILATION AT THE TEMPLE SHOW.—The Temple show being near at hand, something should surely be done to ensure better ventilation in the exhibition tents than there has been in previous years. The heat is generally insufferable, and quite spoils the pleasure from an onlooker's point of view. Perhaps the responsible authorities have already resolved to do something in this matter? *G. Clark, May 13, 1907.*

ANDRENA FULVA.—I hope A. A. W. will not destroy this valuable insect, for this would be a foolish and a cruel thing to do. In bleak spring-time when hive-bees are generally inactive, I find this and other solitary bees usefully employed in "setting" my Apple blossoms. Other varieties collect the injurious larvae of moths and stuff them in a numbed state into their cells to serve as food for their young instead of bee bread. These solitary bees are friends of the fruit-grower, and they need protection as much as birds. The application of a broom and a roller will soon remove their little hillocks. *W. R., Roupell Park, S.W.*

FORCING BY MEANS OF WATER.—I have practised, for many years, similar methods to those mentioned by R. P. B. on p. 177, and have found them valuable for anticipating the season of many hardy flowering plants. For the past five years I have employed a modification of this plan for sending flowers to London during the season. The journey is long, and by the time the boxes are delivered and unpacked the flowers have been cut nearly 24 hours. Under these conditions flowers which are fully or nearly expanded when despatched have but a brief period of usefulness in London. At first there were failures, but the successes were encouraging, and now the bulk of the flowers sent are cut in the bud stage. In some cases the flowers after expansion are slightly smaller than those which open on the plants, but they are fresher and last longer. Rhododendrons, which R. P. B. seems to have failed with, are examples. With this genus the water should be only just chilled. By this method many of the beautiful Sikkim species and hybrids

can be induced to expand trusses of flowers which, if left on the bushes, would be cut by frosts. The Ghent Azaleas are amenable to the same treatment, but *A. mollis* is uncertain. Branches of out-door Camellias are also sent; these and the Rhododendrons are cut as the leading buds show signs of colour. Violets, especially the single varieties, would be useless if sent fully open; the "singles" are gathered when in bud, and the doubles when the flowers are half open. Many of the Poppies—*Papaver orientale*, the Shirley Poppies, and hybrids of *P. nudicaule*—can be safely sent if they are cut just as the calyx shows signs of bursting, and the stalks are at once placed in water. If cut as the spathe begins to unfold, White Arums will develop perfectly; and such *Amaryllids* as *Crinum*, *Clivia*, and *Hippeastrum*, present no packing difficulties, and expand freely if the spikes are cut at the petals of the leading flowers show signs of separating. The flowers keep fresher if their stems are placed in water for an hour or so before they are packed, and on arrival any that flag should be immersed in chilled water for a short time. The water in the vases must be changed daily, the stalks of the flowers wiped dry, and a thin slice cut off the end before replacing them. The *Amaryllids* and Poppies travel best if packed in clean, damp moss. *A. C. Bartlett, Pencazic Gardens, Cornwall.*

STRAWBERRY ROYAL SOVEREIGN.—It is with some surprise that I read F. M.'s remarks, p. 304, on this valuable Strawberry. As a market fruit it is recognised as one of the best varieties in existence, not only for productiveness, but also for quality and flavour, and it is also one of the best for sending in transit, as it does not readily become bruised. It is not quite equal in flavour to British Queen and some others, but I doubt if there is another Strawberry grown which, judged from all points, could excel Royal Sovereign. There are some sorts mentioned by F. M. with which I am not acquainted, but the others I have known for years, and I should certainly give first place to Royal Sovereign on all points, except that the variety British Queen and some others are much superior in flavour. Royal Sovereign received a First-Class Certificate from the Fruit Committee of the Royal Horticultural Society in 1892, and I understand that its flavour was one of its greatest recommendations for that honour. Royal Sovereign has been planted so largely that other varieties have been neglected, with the result that supplies of this fall off earlier in the season than formerly. I remember when The President was first introduced; it held for some years about the same position as Royal Sovereign does at the present time, but its great fault was that when fully ripe, the fruit would not stand transit well. Of all the older varieties, Kitley's Goliath would be most appreciated if we could get it as it was grown in Sussex 35 years ago. Another which deserves mention is Cox's Hybrid (or Elton Pine), a very late, and one of the finest Strawberries for preserving purposes. It might prove both interesting and instructive to have a discussion on the value of the various sorts of Strawberries. Much has been written in favour of Vicomtesse Hericart de Thiery, one of the first to produce a late autumn crop of fruit from plants which had been forced, and afterwards planted out. This autumn-cropping was the only merit I ever recognised in it. There are many varieties which may be suitable for cultivation in private gardens, but for market purposes a Strawberry should possess the three qualities of productiveness, good flavour, and substance, the latter quality to enable it to travel well. *A. H.*

—F. M.'s criticisms on page 304 of the large size of the fruits of Royal Sovereign Strawberry, shown at a recent meeting at Vincent Square, are just from his point of view, but the production of such very large fruits is not at all common even in this variety, and of all the other kinds he mentions not one can equal Royal Sovereign for reliability, fruitfulness, and general amenability to culture, either under glass or outdoors. One reads with astonishment mention of such varieties as *Jas. Veitch*, *La Grosse Sucrie*, *Duke of Edinburgh*, and others as excelling Royal Sovereign in every quality but size. Many of these varieties generally exceed Royal Sovereign in the production of big fruits, but they are utterly flavourless. The exquisite flavour of British Queen or Dr. Hogg is certainly not found in Royal Sovereign, but it

can be relied upon to produce fine crops of fruit, whereas neither of those named by *F. M.* can be so relied upon. How very disappointing is the failure by raisers of Strawberries to combine the productive excellencies of Royal Sovereign with the fine flavour of either of the two varieties I have named. It was supposed to exist in Veitch's Perfection, in Allan's Lord Suffield, and in Laxton's The Laxton—all certainly high flavoured fruits, but disappointment has followed in every case, and it does seem as if high flavour was a product of physical weakness rather than of strength or robustness. No variety has given to growers more entire satisfaction than has Royal Sovereign, but, all the same, we wait hopefully for a better. I have no enthusiasm for big fruits: at the most they represent a very grossly-grown and severely-thinned crop. *A. D.*

SOCIETIES.

ROYAL HORTICULTURAL.

MAY 14.—Notwithstanding the near approach of the "Temple" show, the ordinary meeting of the Committees at the Hall in Vincent Square, on Tuesday last, was attended by a first-rate display of exhibits. Novelties appeared fewer than usual, but the ORCHID COMMITTEE recommended two Awards of Merit, and the FLORAL COMMITTEE six Awards of Merit. No awards were made to novelties by the NARCISSEUS or FRUIT COMMITTEES.

The groups of plants and flowers were extremely varied in character, and together made an excellent exhibition. Probably those which exhibited the highest degree of culture included the collection of Auriculas contributed by Mr. JAMES DOUGLAS, for which a Gold Medal was awarded, and the collection of Odontoglossums from NORMAN C. COOKSON, Esq.

At the afternoon meeting a number of new Fellows were added to the roll of the Society, and Mr. J. C. Stevens, the well-known auctioneer, gave lantern reproductions of his celebrated photographs, representing studies of plants, animals, and curios.

Mr. J. Burt-Davy, who has been absent in the South of Europe, was obliged, through indisposition, to postpone his address to the Scientific Committee on the "Vegetable Resources of the Transvaal."

Floral Committee.

Present: W. Marshall, Esq. (chairman), and Messrs. C. T. Drury, Geo. Nicholson, Jno. Green, T. W. Turner, Chas. E. Pearson, Geo. Paul, W. J. James, W. P. Thomson, E. H. Jenkins, W. Cuthbertson, C. E. Shea, Arthur Turner, H. J. Cutbush, W. Bain, W. Howe, Chas. Dixon, Jas. Douglas, J. W. Barr, C. R. Fielder, J. F. McLeod, Ed. Mawley, R. C. Reginald Neville, E. T. Cook, Jno. Jennings, and R. C. Notcutt.

Mr. JAMES DOUGLAS, Edenside, Great Bookham, Surrey, eclipsed all his former efforts in his beautiful exhibit of Auriculas, and surpassed even his display of last season. On this occasion he staged 400 plants in about 125 varieties, and each plant was a specimen. He had all, or nearly all, of the best varieties in existence, but especially fine were Dean Hole, Ganymede, Thetis, The Bride, and Argus among Alpines; Rev. F. D. Horner and Shirley Hibberd, grey edge; Islas Maid, yellow edge; Mrs. Potts, blue-edged self; and Old Gold, fancy. (Gold Medal.)

Amongst the choicest displays in this excellent exhibition was a group of Rhododendron Pink Pearl exhibited by Messrs. JOHN WATERER & SONS, Bagshot, Surrey. The quality of the flowers was remarkable, and in a setting of beautiful Maples appeared extremely handsome. The group received the high award of a Silver-Gilt Flora Medal.

Messrs. H. B. MAY & SONS, Upper Edmonton, staged Verbenas in great assortment, including varieties of the type known as Auricula-eyed. The best were Unique (mauve), The Queen (salmon), and Favourite (violet purple). We also noticed the dwarf scarlet-flowered *Salvia* named Zurich, a form of *S. splendens* that may be recommended for bedding purposes. The whole exhibit was interspersed with choice Ferns. (Silver Banksian Medal.)

Messrs. CARTER PAGE & Co., 52-53, London Wall, London, E.C., showed an assortment of Sweet Peas, grown under glass; Phlox Drummondii, some choice Antirrhinums, *Diplacus glutinosus*, Fuchsias in variety, and some very fine bunches of *Viscaria oculata*.

Messrs. DOBBIE & Co., Rothesay, N.B., and Marks Tey, Essex, again exhibited Pansies and Violas in great variety. One of the newer Violas is W. H. Edwards, of Plum colour with red striations. Three of the best bedding Violas are Admiral of the Blue, Princess Ida (pale lavender), and Maggie Clunas (primrose yellow). Messrs. DOBBIE also showed some remarkably vigorous Polyanthus, also Anemones and Tulips. (Silver Banksian Medal.)

Sir EDMUND LODER, Bart., Leonardslee, Horsham, Surrey (gr. Mr. W. A. Cook), displayed a number of interesting flowers from the open garden, including several handsome hybrid Rhododendrons raised at Leonardslee. *Limonia trifoliata* has small Magnolia-like flowers on spiny branches. Other interesting plants were *Fendlera rupicola*, *Andromeda arborea*, *Ranunculus pyrenaica*, *Exochordia grandiflora*, *Trilliums*, *Magnolias*, *Maples*, &c. (Silver Banksian Medal.)

Messrs. PAUL & SON, Old Nurseries, Chess-hunt, displayed hardy flowering shrubs—Lilacs in the choicest varieties, both single and double-flowering, Rhododendrons, a large form of the double variety of *Kerria japonica*, *Abelia floribunda*, *Halesia tetraptera*, and many others.

Messrs. J. CHEAL & SON, Crawley, Sussex, showed flowering shrubs. Many beautiful varieties of Rhododendrons, Lilacs, *Magnolias*, Crab Apples, &c., were displayed. A handsome Crab is *Pyrus Malus* var. "transcendent." We also noticed the new *Magnolia Soulangeana nigra*.

Messrs. GEO. BUNYARD & Co., Maidstone, Kent, had named varieties of Lilacs, and an assortment of hardy flowers. *Æthionema hybrida* is a Crucifer with globular heads of rose-coloured flowers shown in this collection.

Mr. A. F. DUTTON, Iver, Bucks., staged a group of winter-flowering Carnations. The flowers were remarkably fine, and the varieties represented the best of these popular flowers, including White Perfection, the improved form of White Lawson, Robert Craig, Mrs. T. W. Lawson, &c. (Silver-Gilt Banksian Medal.)

Another grand exhibit of these Carnations was displayed by Messrs. JAMES VEITCH & SONS, LTD., King's Road, Chelsea, who had in addition *Schizanthus*, *Callas*, *Lantanas*, *Kalanchoe Kewensis*, *Coronilla pygmaea glauca*, some new varieties of *Cannas*, and handsome *Phyllocactus*. As a separate exhibit, Messrs. VEITCH showed some flowering shrubs and trees. At the back of the group were tall plants of *Prunus pissardii*, with *Prunus pseudo-Cerasus* J. H. Veitch, *Cerasus Juliana pendula*, and in the foreground Rose Dorothy Perkins, with large, drooping clusters of flowers, *Hydrangeas*, *Azaleas*, *Maples*, *Prunus sinensis*, &c., the whole forming a group of great beauty. *Azalea roseiflora* was much admired. The small, salmon-pink flowers may be compared to tiny flowers of *Camellias*. (Silver-Gilt Flora Medal.)

Messrs. HUGH LOW & Co., Bush Hill Park, Enfield, also showed vases of Carnations and a few plants of the *Souvenir de la Malmaison* variety. Besides the Carnations, Messrs. Low displayed greenhouse flowering plants. (Silver Banksian Medal.)

Messrs. JOHN PEED & SON, Streatham, Surrey, filled a very large table with *Gloxinias*. These showy flowers were exhibited in all shades of colours, and with self and mottled flowers. The beautiful heliotrope-coloured Countess of Ilchester was amongst the finest, but King Edward VII. (scarlet), Brilliant, and E. Higgs (mottled) are also extremely beautiful varieties. (Silver Flora Medal.)

Mr. L. R. RUSSELL, Richmond, Surrey, showed a handsome group of forced flowering shrubs, *Wistarias* being an especial feature. (Silver-Gilt Banksian Medal.)

Messrs. W. CUTBUSH & SON, Highgate, London, N., exhibited many showy, tender-flowering plants, having Rhododendrons, *Azaleas*, *Verbenas*, *Stocks*, *Roses*, *Cinerarias*, *Ericas*, &c., all prettily displayed. Mention must be made of a fine plant of a white Rhododendron. (Silver Flora Medal.)

Mr. CHAS. TURNER, Royal Nurseries, Slough, staged pyramidal plants of *Azalea indica*; the best examples were Mad. Louise Vervaena (white), Louise Cavellier (white), and of exquisite

form), and President Oswald de Kerchove (salmon pink with white). Mr. TURNER also displayed Lilacs in double and single varieties. (Silver Flora Medal.)

Messrs. W. PAUL & SON, Waltham Cross, again showed rambling Roses in splendid condition. The beautiful white L'Innocence was shown in admirable form as a standard; there were also plants of Jean Ducher, Mad. Charles de Luze—a new H.T. with large, white flowers, having coppery-red centres, and others. (Silver Banksian Medal.)

A very pretty display of Roses was shown by Messrs. BENJ. R. CANT & SONS, Colchester. At the back of the exhibit were tall plants of rambling varieties, the best being Blush Rambler. Among the separate blooms in boxes was a noble flower of the flesh-pink-coloured Princess Marie Merckersky, a hybrid-Tea variety. There were also examples of Killarney, General Jacqueminot, La France, Dean Hole, and other beautiful kinds. (Silver Flora Medal.)

Messrs. FRANK CANT & Co., Colchester, also made an exhibit of Roses. The climbing Minnehaha was crowded with its double pink flowers, which hung in dense clusters. Trier is a white Polyantha variety of much merit. There were also single blooms of Tea and hybrid Tea kinds, prominent amongst which were Betty, Lady Roberts, and Killarney.

Messrs. T. S. WARE, LTD., Ware's Nursery, Feltham, had many Roses among an exhibit of miscellaneous flowers, including Carnations, and hardy subjects. A pan of *Bletia hycinthina* was freely flowered. There were also many *Primulas*, *Saxifragas*, *Irises*, *Asperula suberosa*, *Rhemannia angulata*, &c. (Silver-Gilt Banksian Medal.)

Messrs. H. CANNELL & SONS, Swanley, Kent, showed the beautiful, though small *Phyllocactus* German Emperor, with delicate pink-coloured flowers, and a brilliant display of Zonal, Regal, and Decorative Pelargoniums. (Silver Flora Medal.)

A very handsome strain of herbaceous or large-flowering *Calceolarias* was exhibited by Messrs. J. JAMES & SON, Farnham Royal, Slough. The plants were examples of high culture, and the large flower-trusses were developed on short, sturdy peduncles. (Bronze Flora Medal.)

A small semi-circular group of these plants was also exhibited by C. S. LAYTON, Esq., Thornton, Harrow Weald, Middlesex.

Messrs. JAMES CARTER & Co., High Holborn, London, staged a very imposing exhibit of *Cinerarias* on the floor, with the wall as a background. The group had a central prominent bay, and on either side were other smaller bays, Star or stellate varieties were intermingled with the larger-flowered type, the colours being very beautiful. Ferns and Palms were used to furnish greenery. (Silver Flora Medal.)

J. A. YOUNG, Esq., Stove House, West Hill, Putney (gr. Mr. G. H. Street), displayed a group of heavily-flowered *Schizanthus Wisetonensis*, interspersed with *Cinerarias*, Palms, and *Codiceums*, and edged with *Marantas*, *Dracenas*, *Pandanus*, and *Caladiums*. (Bronze Banksian Medal.)

Mr. G. REUTHE, Keston, Kent, had a large batch of *Primula Sieboldii*, in named varieties, a fine assortment of Rhododendrons, and interesting hardy flowers. *Oxalis enneaphylla* has a pleasing white flower and very dissected rotund leaves. *Antirrhinum asarina* and *Embothrium coccineum* were both shown in flower.

Exhibits of hardy flowers were also displayed by the GUILDFORD HARDY PLANT NURSERY; Messrs. G. & A. CLARK, LTD., Dover; Messrs. GEO. JACKMAN & SON, Woking Surrey, who showed *Trollius* in fine form (Silver Banksian Medal); Misses E. & M. KIPPING, Hutton, Essex; Misses HOPKINS, Barming, Kent (Bronze Banksian Medal); and Mr. H. C. PULHAM, Elsenham, Essex.

Mr. C. W. BREADMORE, Winchester, presented several vases of Sweet Peas. The flowers were scarcely smaller than those developed in the open.

A group of the beautiful *Onco-Regelia Irises* was shown by Mr. C. G. VAN TUBERGEN, jun., Zwanenburg Nurseries, Haarlem, Holland, in varieties some of which have been noted on former occasions, including Hera, Flora, Hecate, Charon, Iris, Yocaste, &c. (Bronze Flora Medal.)

Mr. MAURICE PRICHARD, Christchurch, Hants, showed seasonable hardy flowers. *Pæonia tenuifolia rosea* has flowers like a

beautiful pink Shirley Poppy. A pale form of *Alyssum sextatile* was exhibited under the name of *citrina*. Mr. PRICHARD had also varieties of Bluebells in different colours, including pink and white.

Mr. AMOS PERRY, Enfield Chase, Middlesex, showed an assortment of hardy flowers. The beautiful *Anchusa italica* (Dropmore variety), *Camassia Cusicki*, *Euphorbia Wulfeni*, *Tiarella cordifolia*, *Pentstemon Menziesi*, *Primula Munroi*, and *Iris iberica* were all shown in the best condition. A hybrid *Iris* of the type of *Iris iberica* possessed considerable merit.

Sir JAMES W. MACKAY, 23, Upper Sackville Street, Dublin, exhibited a number of St. Brigid Anemones in vases.

A remarkably fine batch of the blue *Saint-paulia ionantha* was shown by the Marquis of SALISBURY, Hatfield House, Herts (gr. Mr. H. Prime). The plants were very heavily flowered and, interspersed with *Pilea muscosa*, made a very pretty exhibit. (Silver Banksian Medal.)

H. A. MANGLES, Esq., Littleworth Cross, Seale, Surrey, staged three new *Rhododendrons* with large pink flowers.

J. T. BENNETT POE, Esq., 29, Ashley Place, S.W., showed a plant of *Cantua buxifolia* with its drooping pendulous flowers freely developed.

BEES, Ltd., Wapping Buildings, Liverpool, showed a variety of *Mimulus grandiflora* with dark-coloured flowers.

AWARDS.

AWARDS OF MERIT

were recommended to the six plants enumerated below:—

Aubretia "Henry Marshall."—A seedling variety with purple flowers, of rather less size than those of the variety known as A. I. It is exceedingly free in blooming, and it has the quality of flowering later in the season than Dr. Mules or "A. I." Shown by Mr. MAURICE PRICHARD.

Clivia miniata var. *citrina*.—This is a perfectly yellow variety of this well-known greenhouse plant of a pale apricot shade similar to that seen in some of the hybrids of *Hemerocallis*. Shown by the Hon. Mrs. EVELYN CECIL, 10, Eaton Place, who afforded the information that the plant was found growing wild in Zululand.

Gladiolus atrovirens.—This slender-growing species, from Palestine, has violet-coloured flowers, but the three lower segments are striped with white. The general effect is of rich, rather deep violet colour. The leaves are narrow and of bluish-green tint. The inflorescence is generally twisted, or bent, grows about 20 inches high, and bears seven or more flowers each. It is a very interesting species for the plant-lover, but may not equally attract the multitude. Shown by Messrs. WALLACE & Co., Colchester.

Haberlea rhodopensis var. *virginialis*.—This is a pure white variety of this Gesneraceous plant, which was introduced from Roumelia in 1880. (See *Bot. Mag.*, tab. 6651.) The plant is a hardy herbaceous perennial, and its cultural requirements are somewhat similar to those of *Ramondia*. Shown by Mr. R. FARRER, Craven Nursery, Clapham, York.

Hydrangea arborescens var. *grandiflora*.—This variety of *H. arborescens*, a hardy North American species, has larger, pure white flowers than those of the type. Shown by Messrs. PAUL & SON, Cheshunt.

Iris x *Luna*.—A variety of the *Onco-Regelia* section raised by Mr. C. G. VAN TUBERGEN, jun., Haarlem, Holland. It is an improvement on the variety *Artemis*, of which an illustration was published in these pages on May 28, 1904, p. 349. "Luna" has large, handsome standards of a shade of violet, the veins being of deeper tint. The falls are of great width, beautifully rounded, and have a large, very rich purple blotch, the remaining portion being of lighter shade, but having the veinings as deep as on the blotch. It is a flower in which the "pencil" characteristic of this type is seen at its best. Shown by Mr. C. G. VAN TUBERGEN, jun.

Narcissus and Tulip Committee.

Present: Mr. H. B. May (chairman), Miss F. W. Currey, and Messrs. P. R. Barr, R. Sydenham, W. Poupart, F. D. Hall, G. H. Engleheart, A. M. Wilson, J. Walker, J. R. de

Boscawen, J. de Graaff, G. W. Leak, J. Jacob, J. T. Bennett Pöe, E. A. Bowles, J. D. Pearson, A. R. Goodwin, and C. H. Curtis (hon. sec.).

The only collection of *Narcissi* before the committee was one from Miss H. SPURRELL, Bessingham, Norfolk. Noticeable in the group were very beautiful flowers of *Narcissus triandrus pulchellus*, and these were displayed in considerable quantity. Other good things included *Zoe*—a fine poeticus; Agnes Harvey (Leeds), a beautiful flower; Mrs. F. Barclay, Chloe, and May Blossom, the two last-named being seedlings of promise.

Among the collections of Tulips, that from Messrs. R. W. WALLACE & Co., Colchester, was of considerable importance. The fine bank of flowers largely made up of Darwin and May-flowering kinds afforded variety sufficient to satisfy the most exacting. Among the more showy kinds we select *fulgens lutea maxima*, Flame, Inglescombe Pink, a most handsome flower in salmon and buff with bright pink tints; Orange Beauty, Coronation Scarlet, The Fawn, &c. The true Darwin kinds were in great quantity, and they were much admired. (Silver-Gilt Flora Medal.)

A very handsome exhibit of Tulips came from the nurseries of Messrs. ALEXANDER DICKSON & SONS, Dawson Street, Belfast, the group being particularly rich in Darwin kinds. Gold Vase is a very appropriate name for a bold and showy flower of old-gold colour. We also noticed Pride of Haarlem, Margaret, Mdme. Krelage, Rose Queen, Farncombe Sanders, &c. (Silver-Gilt Banksian Medal.)

A similar award was made to Messrs. R. H. BATH & Co., LTD., Wisbech for a very large and representative gathering of Tulips, which embraced the Cottage May-flowering and Darwin types, each represented by the leading varieties.

Another very liberal display of these seasonable flowers came from Mr. ALEX. WILSON, Spilsby, Lincs., the fine bunches being well displayed and of excellent quality. (Silver Flora Medal.)

Messrs. BARR & SONS, Covent Garden, London, W.C., also received a Silver Flora Medal for a large array of beautiful kinds of Tulips, and here again were seen representatives of the Cottage, May-flowering and Darwin types. Particularly good among the latter were Sultan, Phyllis, Clara Butt, Glow, Loveliness, and King Harold.

Messrs. JAS. VEITCH & SONS, LTD., Chelsea, had an exhibit of Tulips chiefly of Darwin and May-flowering sorts in the best varieties. (Silver Banksian Medal.)

Smaller groups or collections were also staged by Messrs. WALTER WARE & Co., LTD., Bath; Mr. MAURICE PRICHARD, Christchurch, Hants.; Messrs. GILBERT & SON, Bourne, Lincolnshire; and Messrs. WM. BULL & SONS, Chelsea.

Orchid Committee.

Present: J. Gurney Fowler, Esq. (in the chair), and Messrs. Jas. O'Brien (hon. sec.), De B. Crawshaw, W. A. Bilney, Fred. J. Hanbury, J. Wilson Potter, H. A. Tracy, H. G. Alexander, W. H. Young, H. J. Chapman, J. Charlesworth, W. Cobb, A. A. McBean, W. P. Bound, F. M. Ogilvie, Francis Wellesley, C. J. Lucas, G. F. Moore, W. Boxall, A. Dye, H. Little, H. Ballantine, and Harry J. Veitch.

Among the most important exhibits was the fine group of *Odontoglossums* staged by NORMAN C. COOKSON, Esq., Oakwood, Wylam (gr. Mr. H. J. Chapman), and the most remarkable of the select varieties of blotched *O. crispum* in the group was the noble *O. crispum* Leonard Perfect, which was the centre of attraction in Messrs. Sanders' group at the Temple show last year, and which was illustrated in *The Gardeners' Chronicle* from that specimen, June 2, 1906, pp. 348-9. Since that time the plant has been divided, but the portion falling into Mr. Chapman's hands shows flowers equal at least to the original, of a clear white, with the whole central area of the segments of a soft purple tint. The flower measures $4\frac{1}{2}$ inches at its widest part, the fringed petals are nearly as broad as they are long, and the labellum is large and showy, thus exhibiting a fine feature which is lacking in many other good forms. The plant has been in flower a month, and was still in fine condition. Next in importance was *O. crispum* Fearnley Sander, whose surface was evenly blotched with reddish purple, the disc of

the lip having a peculiar dark yellow tint; other good forms noted were *O. crispum* Moonlight, with blotched sepals, and a cluster of purple spots in the middle of the petals; *O. c. Abner* Hassall, *O. c. Eustace*, *O. c. Mariae*, *O. c. Peetersii*, *O. c. Whatelyae*, and some unnamed forms, all finely spotted. *O. c. Angela* has very bright purple markings. With the *Odontoglossums* were a selection of the Oakwood hybrid Phaius, including Harold, Norman, Phoebe, Ruby, and Oakwoodensis; also *Cattleya Schroderae* alba and some other showy kinds. (Silver-Gilt Flora Medal.)

Messrs. JAS. VEITCH & SONS, Royal Exotic Nursery, King's Road, Chelsea, staged a bright and effective group, in the centre of which was a very fine specimen of the scarlet *Renanthera imschootiana*, with a nine-branched spike of about 100 pretty flowers. Beside it were the new *Brasso-Cattleya-Lælia* Veitchii and *Brasso-Lælia* Digbyano-purpurata; the remainder of the group was made up of excellent forms of *Cattleya Mendelii*, *Masdevallia Veitchiana*, *Lælia*-Latona, various *Odontoglossums*, including the fine violet-purple blotched *O. ardensimum* Lamus, &c. (Silver Flora Medal.)

DE B. CRAWSHAY, Esq., Rosefield, Sevenoaks (gr. Mr. Stables), showed a group of splendidly grown *Odontoglossums*, among which were *O. crispum* Raymond Crawshaw and *O. c. Crawshawana*, *O. c. Trianae*, and other well-known spotted forms. *O. crispum* Mrs. De B. Crawshaw is a charming white flower, with a delicate rose flush on the sepals; and *O. Rossii* immaculatum, a unique, unspotted variety. Also in the group were a very fine form of *O. crispum* Harryanum and the new *O. Urania* (cristatellum x spotted crispum), the first of the batch to flower, and which adheres closely to *O. cristatellum* in form and in the sepia-brown blotching. It is expected that others of the batch will show more of the character of *O. crispum*. (Silver Flora Medal.)

Messrs. HUGH LOW & Co., Bush Hill Park, Enfield, had a very fine group composed principally of about sixty plants of their excellent type of *Cattleya Mendelii*. The flowers were generally of the mauve-lipped class, but there were several very pretty blush-white forms, one of them having the petals and lip finely crimped and beautifully veined with light rose colour. Two fine specimens of *Cattleya Skinneri*, *Cölogyne pandurata*, a very dark *Lælia-Cattleya* Dominiana, *Cattleya Mozart*, *C. Parthenia* Prince of Wales, and others were also included. (Silver Flora Medal.)

Messrs. SANDER & SONS, St. Albans, staged an effective group, at the back of which were several very fine specimens of *Dendrobium thyrsiflorum*, with from seven to twelve flower spikes; and a well-flowered lot of *Dendrobium Devonianum*. On either side were two fine examples of *Lælia-Cattleya* Hyeana (Lawrenceana x purpurata) carrying six flowers each, the petals of one being veined with purple, and the lip of a deep claret colour. With these were two specimens of *Trichopilia crispa* Champlatreux variety with rich crimson labellums; the pretty *Bifrenaria Harrisoniae* pubigera, *Angraecum acutum*, and the rare *Cölogyne virescens* with cream-white flowers having blackish markings on the lip. Among the *Odontoglossums*, the best was a home-raised *O. crispum*, with good flowers, having the segments heavily blotched with reddish purple; another handsomely blotched flower was obtained by crossing *O. Wilckeanum* and *O. crispum*. (Silver Banksian Medal.)

Messrs. J. CYRER & SONS, Cheltenham, staged a small group in which were two very fine, large-flowered, deep magenta-rose forms of *Miltonia vexillaria*, and two of an equally large form with white labellums; a fine *Cattleya Skinneri* with white flowers having a slight lilac tint; *Cattleya intermedia* alba and some well-bloomed *Leptotes bicolor*. (Silver Banksian Medal.)

R. I. MEASURES, Esq., Cambridge Lodge, Camberwell (gr. Mr. Smith), staged a group in which about thirty-six species and varieties were represented. *Cattleya Mendelii* and *C. Lawrenceana* were well shown; also *Cymbidium Lowianum* and *C. Low-grinum* (Lowianum x tigrinum), Phaius Norman, *Masdevallia O'Brieniana*, *M. trinema*, *M. xanthina*, *M. ignea* Ellisiana, *M. Houtteana* and other species. (Silver Banksian Medal.)

J. GURNEY FOWLER, Esq., Glebelands, South Woodford (gr. Mr. J. Davis), sent *Odontoglossum Ossulstonii* (Glebelands variety) (crispoharryanum x *Pescatorei* Charlesworthii), a very pretty variety with white ground colour, bearing distinct violet-purple blotching. The lip is broad, white in front, and with purple markings around the yellow crest.

Major G. L. HOLFORD, C.I.E., C.V.O., Westonbirt, Tetbury (gr. Mr. H. G. Alexander), showed *Lælio-Cattleya Ganymede illustre* (L. Latona x C. Schröderæ) differing from the one shown at the last meeting by having the yellowish petals bearing purple lines up the middle, the front of the lip being deep claret-crimson.

W. A. BILNEY, Esq., Fir Grange, Weybridge Heath (gr. Mr. Whitlock), sent *Cattleya Mossiæ* "Mrs. W. A. Bilney," a very large and handsome flower, with broad, light-rose coloured sepals and petals, the handsome lip having a chrome-yellow disc with crimson marking in front.

Messrs. CHARLESWORTH & Co., Heaton, Bradford, showed *Cattleya Schröderæ* "The Bride," a clear, white flower with bright yellow centre to the lip and yellow lines on the lateral sepals. Also a fine *Lælio-Cattleya Wellsiana*, and a good spotted *Odontoglossum*.

Monsieur MERTENS, Mont St. Amand, Ghent, showed several pretty hybrid *Odontoglossums*.

Mr. H. A. TRACY, Orchid Nursery, Twickenham, sent *Cattleya Mossiæ* "Mrs. H. Rider Haggard," a very distinct white flower of good substance, with a yellow tinge in the centre of the lip and distinct slate-blue marbling in front.

AWARDS.

AWARDS OF MERIT.

Odontoglossum crispum xanthotes "White Lady."—A very fine variety, with well-formed, clear white flowers, with an occasional orange-coloured spot on some of the sepals, and a clear orange-coloured disc to the lip. The plant shown was very finely cultivated, and bore a magnificent spike of flowers. From F. MENTITH OGILVIE, Esq., The Shrubbery, Oxford (gr. Mr. Balmforth).

Oncidium leucochilum "Mrs. F. J. Hanbury."—A very distinct form of the pretty species originally imported from Guatemala in 1835, and later from Mexico. The variety Mrs. F. J. Hanbury differs from others in having the sepals and petals almost entirely of a purplish-chocolate colour, well contrasting with the clear-white lip. The plant shown had a spike 4 feet in height, with fifteen branches, and bearing about 100 flowers. From FREDERICK J. HANBURY, Stainforth House, Upper Clapton.

Fruit and Vegetable Committee.

Present: Geo. Bunyard, Esq. (chairman); and Messrs. Jos. Cheal, W. Bates, Geo. Kelf, Edwin Beckett, Alex. Dean, H. Parr, A. R. Allan, W. Pope, R. Lye, J. Davis, P. D. Tuckett, C. G. A. Nix, Charles Foster, Owen Thomas, J. Jacques, and James Vert.

Three boxes of very large fruits of Royal Sovereign Strawberry were shown by the Marquis of SALISBURY, Hatfield House (gr. Mr. H. Prime). (Silver Banksian Medal.)

A couple of dishes of Lane's Prince Albert Apple were shown by Messrs. LANE & SON, Berkhamsted, for which a cultural commendation was awarded.

The same award was also given for an early Marrowfat Pea named World's Record, shown by Messrs. SUTTON & SONS, Reading, and for Rhubarb Hobday's Giant, shown by Mr. G. HOBDAV, Havering Road, Romford.

The Pea was raised from Harbinger and Early Giant, and it is claimed to be 10 days earlier in cropping than the latter. The pods are 4.5 inches in length, and the haulm is dwarf.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

MAY 2.—Committee present: E. Ashworth, Esq. (chairman); and Messrs. Cypher, Thorp, Parker, Ashton, Keeling, Walmsley, Warburton, Rogers, Sander, Ward, Cowan, Stevens, Thompson, P. Smith, Duckworth, Williamson, and Weathers (hon. sec.).

This meeting closed the 1906-1907 session, and was well attended by the members. The "Sander Cup" competition was also completed at

this meeting, and the result will be made known at the annual meeting of the society on May 16.

W. THOMPSON, Esq., Stone, exhibited a grand display of plants for which he was awarded a Gold Medal.

A. WARBURTON, Esq., Haslingden, gained a similar award for a charming group.

Other groups were staged by R. ASHWORTH, Esq., Newchurch (Silver Medal), and by Messrs. CYPHER & SONS, Cheltenham (Silver Medal).

The following Awards were granted:—

FIRST-CLASS CERTIFICATES: *Odontoglossum Prince Edward of Wales* (O. Rolfe x O. Harryana crispum), shown by W. THOMPSON, Esq.; and O. crispum President Laurier, exhibited by A. WARBURTON, Esq. AWARDS OF MERIT: *Miltonia Roezlii magnifica*, exhibited by H. J. BROMILOV, Esq.; *Oncidium monachicum* var. *metallicum*, *Renanthera Imschootiana*, *Odontoglossum crispum* "Queen of Spain" (disbudded), O. c. A. J. Balfour, O. x Prince Albert (ardentissimum x Wilckeanum), O. crispum amabile; O. Harryanum var. *Elinor*, *Masdevallia Chamberlainiana*, *Odontoglossum Adrianae* Lord Kitchener, O. x *Phoebe Walton* var. (cirrhosum x *Luciana*), O. c. Ronald, O. amabile var. *mosiacum*, O. *mulus magnificum*, and O. *Rolfæ splendens*, all shown by W. THOMPSON, Esq.; O. *uro Skinneri alba*, O. c. *Pink Beauty*, O. species (unnamed), O. *Lambeauium* Warburton's var.; *Cattleya intermedia cœrulea*, the last-named five shown by A. WARBURTON, Esq.; C. *Mendelii* General Botha from the nursery of Messrs. H. Low & Co.; and C. *Lawrenceana Hyeana*, exhibited by R. ASHWORTH, Esq.

INTERNATIONAL EXHIBITION AT MANNHEIM.

MAY 1.—The Jubilee International Exhibition which was opened on the above date, writes a correspondent, "was of special interest on Tuesday, May 7, when the Orchid competitions filled the large hall in the Rose garden. This hall (about the size of the Royal Horticultural Society's hall in Vincent Square) presented a fine sight with the Orchids arranged on long tables. The competitions were numerous, and included those for a collection of Orchids in 100 varieties, a collection of botanical Orchids, a collection of Dendrobiums, and a collection of Cypripediums. Prize winners included Messrs. BEYRONT, of Berlin; MARON, of Brunoy; and HUGH LOW & Co., of Bush Hill Park, who filled an entire table with a large and interesting group representing most of the Orchid families in cultivation, and were awarded two first and one second prize in the above competition. Messrs. Low also received a Gold Medal for a group of English and American perpetual-flowering Carnations, in which were included several novelties.

At no time did the attendance seem very numerous, neither was there so much enthusiasm to be seen as is common at similar shows in England; however, if the Germans excelled in cultivation as they do in artistic arrangement, we English would be outclassed."

Obituary.

REV. S. EUGENIE BOURNE.—We regret to announce the death on the 11th inst. of the Rev. S. Eugenie Bourne, B.A., Vicar of Dunstan, near Lincoln. Mr. Bourne was a member of the Royal Horticultural Society's Narcissus and Tulip Committee, and was as keen as other florists in his admiration for proportion in flowers. It was a speech made by Mr. Bourne, at the dinner of the Midland Daffodil Society, at Birmingham, last year, that prompted our article on "Balance in Flowers," published in these pages on May 12, 1906. Deceased had a keen appreciation for Daffodils. He deprecated mere size in flowers, and at all times encouraged an appreciation for "balance" or symmetry. If, he said, a flower first appealed to the observer by reason of an extra large perianth, or an unusually and disproportionately long trumpet, such a flower was not all it should be. Neither this nor that special feature should be unduly prominent. A big trumpet must be "balanced" by a large perianth, and so on. Mr. Bourne was the author of *The Book of the Daffodil*, published by Mr. John Lane. He will be much missed by a large number of horticultural friends.

WILLIAM O'REILLY.—We learn through the courtesy of Prof. Sargent of the death of this well-known British gardener, at Parque Cousino, Lota, Chili. Deceased succumbed to an attack of apoplexy on January 7. The late Mr. O'Reilly was an excellent cultivator, and he made the Cousino Garden at Lota one of the most interesting gardens in the world. Most horticultural visitors to Chili knew the gardens and its late gardener, who is especially mentioned in Ball's *Notes of a Naturalist in South America*, wherein the author states that deceased came from Wexford, in Ireland, and that he received training in the Royal Gardens at Kew. Ball further says: "I let the Parque at Lota with my memory full of the pictures of a spot which, along with Mr. Cooke's famous garden at Montserrat, near Cintra, and that of M. Landon, in the Oasis of Biskra, I count as the most beautiful garden that I have yet seen."

JESSE LEE.—In the American horticultural Press we note the death of Jesse Lee, at Marshall, Mich., U.S.A., on Saturday, March 30, after an illness of three weeks. The deceased was nearly 85 years old, and his demise was due to his advanced years. He had lived at Marshall 47 years, having emigrated directly from Kent, his native county.

DR. ROBERT BARNES, M.D.—The death of Dr. Barnes, at Bernersmede, Eastbourne, at the age of 90 years, is announced in *The Times*. Deceased's father was Philip Barnes, of Norwich, who, in conjunction with James De Caille Sowerby, founded the Royal Botanical Gardens in Regent's Park. At the time of his death deceased was one of the oldest Fellows of the Linnean Society.

THE WEATHER.

THE FOLLOWING SUMMARY RECORD of the weather throughout the British Islands, for the week ending May 11, is furnished from the Meteorological Office:—

GENERAL OBSERVATIONS.

The weather was generally cloudy or overcast, but very considerable intervals of sunshine were experienced in the south and east of England. Falls of rain were rather frequent in most districts, and thunderstorms occurred at times in several English and Scottish districts. A thunderstorm also passed over Dublin on Monday.

The temperature was below the average in Ireland S. and the Channel Islands, above it elsewhere, the excess amounting to 4.6° in the Midland Counties, and about 6° in England E. and N.E. As a general rule the highest of the maxima were recorded on the 11th. In England E. (at Hillington) the thermometer rose to 80° and in England N.E. to 79°; in Scotland N. the highest reading was 66° and in Ireland 68°. The lowest of the minima, which were mostly recorded on the 6th, ranged from 37° in Scotland E. and 39° in England E. and in Ireland, to 38° in Scotland W. and to 44° in the Channel Islands.

The mean temperature of the sea.—There was a very general increase in the warmth of the water on all parts of the coast, amounting in many places to more than 1°. The actual values ranged from 51.6° at Newquay and 50.9° at Seafield to 46° or rather less on most parts of our north and north-east coasts, and to 44° at Wick.

The rainfall exceeded the average except in Scotland E. and England E. and N.E.; in the western districts the excess was large.

The bright sunshine was just equal to the average in England S., and above it in England E.; elsewhere, however, there was a deficiency. The percentage of the possible duration ranged from 68 in England E. and 45 in England S. to 24 in Scotland W., and to 21 in England S.W.

THE WEATHER IN WEST HERTS.

Week ending May 15.

Exceptionally warm and very wet.—Throughout the last ten days the temperature has continued very warm, both during the daytime and at night. On the two warmest days, which occurred during the past week, the highest readings in the thermometer screen were respectively 78° and 78°. Both of these readings are the highest as yet recorded here this year, and also higher than any previously recorded so early in May. During the past week the thermometer exposed on the lawn never fell lower than 58°. This is a very high extreme minimum for the week, which includes the almost constantly recurring cold period in May, lasting from the 9th to the 14th. At 2 feet deep the ground is now 8° warmer, and at 1 foot deep 8° warmer, than is seasonable. In the middle of the week the reading at the latter depth was as much as 5° warmer than the average. Rain fell on five days, to the total depth of 1½ inch, making this the wettest week since the last week in December, or for four and a half months. On the wettest day nearly three quarters of an inch of rain was deposited, which is the heaviest fall in any one day since November 8 last, or for more than six months. During the week 1½ gallon of rain water has passed through the percolation gauge on which short grass is growing, and 8½ gallons through the bare soil gauge. The sun shone on an average for 6½ hours a day, or for half an hour a day in excess of a seasonable duration. On the first two days of the week the winds were rather high, but since then light airs have prevailed. There was again about a seasonable amount of moisture in the air at 8 p.m. A selected Horse-Chestnut tree came first into flower in my garden on the 10th, or three days earlier than its average date in the previous 16 years, and a fortnight earlier than last year. E. M., Berkhamsted, May 15, 1907.

EDITOR AND PUBLISHER.—Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication, or referring to the Literary department, and all plants to be named, should be directed to the EDITOR. The two departments, Publishing and Editorial, are quite distinct, and much unnecessary delay and confusion arise when letters are misdirected.

ADJUSTMENT OF A SUNDIAL: *W. G. S.* You do not say what kind of sundial you propose to erect—whether one of the horizontal type, such as is usually put on a pedestal in a garden; or a vertical dial to be attached to a wall, or an equatorial dial, which is different again from either. Assuming, however, that you contemplate erecting a horizontal dial, there is no definite length for the gnomon, but for a 12-inch dial, one of 8 inches long with a base of 4 inches would be appropriate. The base must be set perfectly horizontal, and it is important that the gnomon should make an angle with the base, and with the horizon, equal to the latitude of the place at which it is erected, and for Worcester Park this will be 51½ degrees. To mark off the position of the figures it is best to proceed as follows:—First attach the gnomon firmly to the dial; then set the dial in position on the pedestal with the gnomon accurately in the meridian. To do this a compass may be used, correcting it, of course, for magnetic variation; but a better way is to get correct Greenwich time from a post office (where at 10 o'clock a.m. they get a time signal from Greenwich), and set your watch to it. Then by subtracting one minute for the difference in longitude between Greenwich and Worcester Park you will get the local mean time for the latter place, and by adding to this local mean time four minutes for the equation of time, you will have the time at which the sun is in the meridian, and the dial must then be turned until the shadow of the gnomon falls in the same vertical plane as the gnomon itself. This will give the noon line, which it is most important to get accurately. The position of the other lines may then be marked by noting the position of the shadow at intervals of one hour, or half hour, after noon; and the hours before noon can be marked similarly next morning by noting the position of the shadow at precisely 8, 9, 10, and 11 o'clock. The correction we have given for the equation of time will serve till (say) May 25, after which date it will require to be modified in accordance with the change in the equation of time, as shown in Whitaker's or any similar almanac.

ANTS IN GREENHOUSES: *A. D.* If you can trace the haunts of these pests in the soil, they can be easily exterminated by pouring weak carbolic acid, bisulphide of carbon, or even boiling water, down their burrows. Should you not be able to trace them to their home, spread Ballikrain Ant Killer in their paths, but remember this and the acid and bisulphide of carbon are most deadly poisons, and adopt precautions accordingly.

BLACK CURRANT BUD-MITE: *G. P.* Destroy the two affected bushes and dust the healthy ones with a mixture of unslaked lime and flowers of sulphur in the proportion of one part of the lime to two parts of sulphur. As the insects are now migrating from bud to bud no time should be lost in making the application. See details of Mr. Collinge's treatment in our issue for January 26, 1907, p. 56.

BOOK ON FLORAL DESIGN: *J. W. and others.* The book on *Floral Design*, by W. D. Wiltshire, of which a notice appeared in our last issue (p. 301), can be obtained from our publishing department, price 1s. 1½d. free by post.

CARNATION DISEASED: *J. S. H.* We find no fungus present. The plant has rotted at the stem near the base, and few roots appear to

have developed or they have been killed. This suggests something wrong with the soil. Discontinue the use of manures, and see that the plants receive extra care in the matter of watering.

FORESTRY JOURNAL: *W. R. R.* Communicate with Prof. Fisher, Oxford, the Editor.

GRAPES: *F. C. S., Lincoln.* The injury is caused by *Gloeosporium ampelophagum*. Sprinkle the branches when damp with a mixture of one part powdered quick-lime and two parts flowers of sulphur. Remove all diseased fruit and leaves.

HIPPEASTRUM FLOWERS FADING: *A. T.* The *Hippeastrums* should last at least a fortnight in bloom. Probably the house in which you keep them is too warm, and not sufficiently ventilated. Remove the plants to a cooler, better ventilated house just before the flowers expand.

INSECTS ON FERNS, &c.: *H. P.* The pests are weevils. Trap them with slices of Carrot or Potato. They can also be killed in their haunts by carbon bi-sulphide poured down their burrows.

KAINIT AS A MANURE: *J. S. M.* This for general purposes is the cheapest and most economical potash manure to use. The best time to use it is during the winter, but it can be applied at any time to growing crops. Apply half a pound or less to every square yard.

MARKET PRICES, &c.: *G. B.* Either *The Fruit, Flower and Vegetable Trades' Journal*, 139-140, Salisbury Court, Fleet Street, E.C., or *The Fruit Grower, Fruiterer, Florist, and Market Gardener*, 1, 2, 3, Salisbury Court, Fleet Street, London, E.C., would furnish you with the information.

MELON LEAVES: *W. W.* We find no trace of disease. The leaves appear to be injured from some check; you will see that the youngest tissue around the margins has been injured the most. Strong fumigations or syringings of insecticide would cause such injury.

MICE INJURING STRAWBERRIES: *E. N.* As you have proved traps to be useless for ridding your land of mice and voles, the alternative is to employ poison, but do not delay in putting it about, for later when the fruits are ripe, poisoned mice would be very objectionable near them, and there would be also the danger of the mice eating the fruits immediately after consuming the poison. We should think the "Liverpool Virus" would be useful for the purpose.

NAMES OF FLOWERS, FRUITS AND PLANTS.—We are anxious to oblige correspondents as far as we consistently can, but they must bear in mind that it is no part of our duty to our subscribers to name either flowers or fruits. Such work entails considerable outlay, both of time and money, and cannot be allowed to disorganise the preparations for the weekly issue, or to encroach upon time required for the conduct of the paper. Correspondents should never send more than six plants or fruits at one time: they should be very careful to pack and label them properly, to give every information as to the county the fruits are grown in, and to send ripe, or nearly ripe, specimens which show the character of the variety. By neglecting these precautions correspondents add greatly to our labour, and run the risk of delay and incorrect determinations. *Correspondents not answered in one issue are requested to be so good as to consult the following numbers.* **FRUITS:** *W. G. Gough.* Winter Pearmain.

PLANTS: *C. S.* The *Marattia* is *M. podolepis*, Sturm, which is sufficiently distinct for garden purposes from *M. cicutifolia*, with which it is united in Hooker and Baker's *Synopsis Filicum*, where a wide view of species is taken. It is not *M. attenuata*.—*T. R.* *Exochorda grandiflora*.—*Finchley.* *Oncidium caesium*.—*W. B. A.* *Odontoglossum triumphans*, but of a rather peculiar shade of colour.—*T. E. G.* *Pteris sinensis*; remove the plant to a cooler house. The Orchid appears to be *O. maculata*, but without foliage it is difficult to name correctly. The insect next week.—*A. C. M.* The climber is *Stauntonia hexaphylla*; the yellow flower *Arnebia echinodes*. *H. H.* 1, *Callicarpa purpurea*; 2, *Prunus Padus*; 3, *Metrosideros floribunda*; 4, *Abutilon megapotamicum*.—*W. S.* *Flants*. 1, *Cercis Siliquastrum* (Judas Tree); 2, *Prunus sinensis flore pleno*; 3, *Ribes aureum*; 4, *Colutea arborescens*; 5, *Tiarella cordifolia*; 6, *Prunus*

Padus.—*E. C.* 1, *Euphorbia Lathyrus*; 2, *Maurandya Barclayana*; 3, *Akebia quinata*; 4, *Spiraea Thunbergii*. *G. L. F.* *Daphne collina*.—*A. W. G.* 1, *Lycium sinense*; 2, *Gentiana verna*. Thanks for one shilling (for R.G.O.F. Box).—*W. B.* *Odontoglossum triumphans* of peculiar marking. — *V. I. I.* 1, *Oncidium sarcodes*; 2, *Pleurothallis ornata*; 3, *Stelis micrantha*; 4, *Masdevallia simula*; 5, *Oncidium cheiroporum*; 6, *Odontoglossum blandum*.—*E. B.* *Helixine Soleirolia*.—*G. W.* Please send a better specimen.

PEACH TREES DECAYING: *G. J. H.* The injury is caused by a fungus (*Botrytis*), which commonly attacks imperfectly-ripened wood, or young shoots that have suffered a chill. All diseased shoots should be cut off and burned, otherwise the disease will spread. After pruning spray the trees with a rose-red solution of permanganate of potash dissolved in water.

PLANTING OF FLOWER BEDS: *A Reader.* As your flower beds are situated in front of the house and are surrounded by plenty of grass, bright colours may be used without any danger of producing gaudiness. We have prepared a colour scheme of red, pink, and yellow. It is so near the planting season that it would be useless to suggest the use of any plants other than those which may be readily purchased. Your beds are of a formal character, and the planting of Nos. 1 and 5 should be of similar composition, and Nos. 2 and 4 should also be planted alike, or nearly so. In the first-named pair, plant a specimen of *Grevillea robusta* (about a foot to 18 inches high) a foot inwards from each point of the beds; plant the bed with good single-flowered tuberous Begonias edged with a band of *Gazania splendens*. For Nos. 2 and 4, along the centre at equal distances, plant three fair-sized *Cordyline australis* (often sold as *Dracaena indivisa*). Select a few plants of Ivy-leaved *Pelargonium* *Mdme. Crousse*, or any similar pink variety, about 9 to 12 inches, trained to upright stakes, and place one plant between each *Cordyline* and outside the two end plants. Plant at one foot from the edge a row of the same variety along each side of these beds, putting the plants at 2 feet apart. Edge them with a good tricoloured *Pelargonium*, such as Mrs. Henry Cox or Mrs. Pollock, and fill in the rest of the bed with a good red-flowered bedding *Pelargonium* such as Paul Crampel or King Edward VII. No. 3 should have a good plant of any red-flowered *Canna* in the centre, edged with dwarf rose-coloured *Begonia semperflorens*, and filling up with *Calceolaria amplexicaulis*. This combination, with care and attention in the matters of watering and manuring later on, should give you a good display of flowers until late in the autumn. The pink Ivy-leaved *Pelargoniums* should be kept lightly tied in the shape of small pillars, and the tri-coloured varieties should be kept free of flowers.

ROSES FAILING TO GROW: *A. T.* It is probable that the plants being very much dried when you received them have died almost to the roots. It would be as well to cut the tops back, keeping the soil only just moist until the roots become active. The address you refer to should be Rio de Janeiro not San Domingo.

"SEAKALE" BEETROOT: *Cook.* The full-grown leaves may be cut from the growing plant, and, after being cleansed in two or three waters, plunged into slightly salted water after bringing it to the boiling point. The time required is from 15 to 20 minutes. Another method consists in cutting the midribs of a number of the leaves, cleansing and shortening them to 6-8 in., afterwards tying them in bundles of 20 as is done with Asparagus. This latter is the better way, as the ribs require more cooking than the thin part of the leaf. Like Seakale and Asparagus, this vegetable may be served with butter sauce, &c.

THE

"LINNÆUS" BI-CENTENARY.

DURING the present week the attention of botanists has been directed to Sweden, in which country Linnæus was born on May 23rd, 1707. The botanical world everywhere has actively celebrated the bi-centenary of the great botanist's birthday. The University at Upsala has headed all such celebrations, it being the University where Linnæus occupied the first chair of botany. It is said that his ancestors took their surname from a large lime tree or Linden, growing in the garden of Linnæus' birthplace, at Rashult, in the Swedish province Smaland. Upsala, a pleasant, ancient Swedish town, is famous for its fine cathedral, where Linnæus' tomb is erected, and for the Museum and "Linnæus" Hall, of which we reproduce an illustration at fig. 136. But few of Linnæus' original specimens and papers are now contained in the hall at Upsala, and though Sweden may view this matter with pardonable regret, yet there can be little doubt that the collections which have found their way to this country have proved of far greater value to botanists of all nations than would have been the case had they remained at Upsala. The story as to how the collections ever came into the possession of Britain is interesting. After Linnæus' death they

passed to his son, whence, he dying without heir, his mother, the sole executrix, came into possession of them. Soon afterwards she offered them to Sir Joseph Banks, then scientific adviser to George III., but, for some reason or other, Banks did not secure them for the nation. At that time a young Norwich doctor called on Sir Joseph, telling him that he had taken much interest in botany and that he would like to do something for the science. Banks then spoke to this young well-to-do gentleman about the offer of Linnæus' collection, and he (the late Sir James Smith), after consultation with his father, bought the whole of the collections, books, manuscripts and the world's greatest herbarium for a very low sum.

This put Sir James at once into a prominent position in the world of botanists, and a few

Upsala, which are of a very important character.

Linnæus, or, as he was afterwards known, Carl von Linné, showed from early childhood a great interest in plant and insect life, much to the disappointment of his father, who was a pastor, and wanted his son to take up theological studies. Linné followed his own inclinations and went to the University Lund, where, under great privations, he studied for some time, afterwards going to Upsala, where, at the expiration of two years, he was appointed assistant lecturer in botany.

In 1732 Linné commenced his travels abroad, visiting Lapland. The results of his observations made during this journey were not published until several years later, during his residence in England, where he arrived towards 1736. Linné visited the gardens at

[From the original by P. Krafft, sen.]

CARL VON LINNÉ.

In the left hand is a spray of *Linnæa borealis*.

of these gentlemen met in 1778 and founded a society, which they called the Linnéan Society. After Smith's death this Society, which in the meantime had become an important institution, bought his collections, and they are now preserved in that Society's rooms at Burlington House. Thus the Linnéan Society has appointed a special representative to attend the celebration at Upsala and to present its Linnéan Gold Medal, to be held by the University of Upsala. Their choice has fallen upon Mr. Wm. Carruthers, F.R.S., who, during his presidency of the Society, was honoured by a mission to offer the fellowship of the Society to the then Crown Prince of Sweden. Mr. Carruthers, accompanied by the Society's excellent Secretary, Mr. Daydon Jackson, is at present taking part in the functions at

Chelsea and Oxford, procuring there many rare plants. He visited Martyn, Rand, Miller, and Sir Hans Sloane, but though he carried a letter of introduction to this great naturalist, he was received somewhat coldly by him. This, however, did not diminish Linné's enthusiasm for England, especially London.

From England he went to Leyden, and afterwards travelled to Antwerp, Brussels, Paris, &c., returning eventually to his native country, after an absence of comparatively few years from Sweden.

The number of important publications he issued demonstrate his activity. His first publication was his *Systema Naturae* (1735), followed in 1736 by his *Fundamenta Botanica* and *Bibliotheca Botanica*. In 1737 appeared his famous *Genera*

Plantarum, which is perhaps the most important and valuable of his works. In the same year appeared *Corollarium Generum Plantarum*, and a book extremely rare at the present day, his *Viridarium Cliffortianum*. Not until this year his *Flora Lapponica* was published; and at short intervals was passed through the press his *Critica Botanica*, which he dedicated to his friend, Prof. Dillenius. Other publications quickly followed, of which the most important are *Hortus Cliffortianus* and *Classes Plantarum* (1738), which practically forms the second part of his *Fundamenta Botanica* and contains a careful review of all the systems of botany from Caesalpinus (1583) up to Linné's

numerous, and his memory will be likely to last as long as there is vegetation upon this globe. Not only have botanists every reason to revere the memory of Linnæus, but gardeners also have gained much from his classification. As long as plants are cultivated, and it is necessary to speak of them, and write of them, even so long will some form of classification and nomenclature be necessary.

The bi-nominal system of nomenclature established by Linnæus, who gave every plant a generic, or family name, as its first title, and a second or specific name to mark its individuality, is the most convenient system science has known.

as in *O. Hallii*, bearing a great horse-shoe shaped blotch (the points at present occasionally broken off) upon a clear yellow ground. Around the apex is a marginal row of spots as in *O. Hallii*, with its inward roll in the centre. Crest as in *O. Hallii* with fewer, shorter filaments; column white, wings almost entire at edges except one thick cirrus; anther cap intermediate. The bulb is $2\frac{1}{2} \times 1\frac{1}{2}$ inches, and developed a 16-inch spike with seven blooms. When a strong plant this will prove a fine addition to the yellow ground garden hybrids. *O. Hallii*, as a species, appears as strong as *O. Harryanum* in perpetuating its characteristics, undoubtedly because both of them are purer than either *O. crispum* or *O. nobile* from the absence of other species growing among them. In raising a race of hybrids from the "Lionel Crawshaw"

FIG. 136.—THE TWO-HUNDREDTH ANNIVERSARY OF LINNÆUS' BIRTH. VIEW OF THE MUSEUM AND "LINNÆUS" HALL AT UPSALA.

own time. There was a little longer interval before, in 1745, his *Oländska och Gothländska Resa* appeared, which was followed by his *Flora Suecica* and *Fauna Suecica*.

During the summer of 1746 Linné went to West Gothland, and, returning in the autumn, published shortly afterwards his *Westgota Resa*. At this time he came into possession of a valuable herbarium which belonged to Dr. Paul Hermann, and based upon this collection, he published his well-known *Flora Zeylanica*. His students' *Materia Medica* was published in 1749.

So this very active and prolific writer published within a few years a series of books which have retained their value and importance until the present time. Linné's labours were rewarded by many high honours, which were conferred upon him from many countries; his monuments and portraits are

NEW OR NOTEWORTHY PLANTS.

ODONTOGLOSSUM × LEO
(*O. HALLII* × *O. TRIUMPHANS*, VARIETY LIONEL CRAWSHAY).

THIS is the first hybrid which has flowered, having this unique form of triumphans as a parent. It is from a cross made on March 3, 1901, and the seed was sown on June 28, 1902; the plant bloomed on May 16, 1907, upon the fourth bulb. The bulbs are intermediate between the parents in habit, and the leaves are similar to those of *O. Hallii*. The spike is more like that of *O. triumphans*. The flowers are of circular form with a rich yellow ground colour. The sepals have three rows of brown blotches as in *O. Hallii*, and the petals are marked by numerous spots arranged in a cluster all over the base, separated from the outer blotch as in *O. triumphans*; the edges are denticulate. Lip of the same form as in the male parent, the shoulders being a little recurved

variety of *O. triumphans* I shall be able to conclusively prove the influence of a marvellous form, as compared to that of an ordinary one, upon its progeny. *De B. Crawshaw, May 20, 1907.*

A BEURRÉ DIEL PEAR TRAINED AS A BUSH.

AT fig. 137 we have reproduced a photograph kindly sent us by Mr. J. Udale, showing a plant of Beurré Diel Pear, which has been cultivated in the bush form. The photograph was taken several weeks ago in the experimental gardens at Droitwich, Worcestershire, and the subject illustrated is not without interest in the light of the discussion that is taking place in these pages upon the question of pruning fruit trees. We believe the specimen now presented has been brought into its present condition by the practice of a moderate amount of pruning, and the shape of the specimen and profusion of flower it bore are certainly satisfactory.

VEGETABLES.

BOLTING AND NON-BOLTING CABBAGES.

DURING the past few weeks complaints, such as were heard two or three years ago, have again been made of the erratic habits of autumn-sown and planted Cabbages. In some cases many from one batch have started to flower prematurely, whilst in others very few or none have so bolted. Why, under similar conditions, some thus bolt and others do not, presents a problem that Cabbage growers would gladly have solved. Some light has been thrown on the matter in two private gardens in Middlesex. In one case a good breadth of Cabbage plants raised from

Some two or three years since, Messrs. Sutton & Sons, Reading, made, in the early autumn, sowings of many well-known varieties of Cabbages, and they transplanted seedlings from each stock. Each variety was treated alike, and their habits noted in the spring. The results were published in the *Gardeners' Chronicle*, June 10, 1905, p. 354, and they showed that the primary cause of premature bolting was unfitness of the special variety for autumn sowing, although it may possess special and distinctive merit when sown in the spring. The same nursery firm have, during the past and the present years, been conducting similar trials, but on a larger scale. Many thousands of seedling Cabbages were transplanted from a sowing

far too late for spring Cabbages, and sowings were made of seed about the middle of September, the plants remaining in the seed beds and planted out in March, many of the large summer section which habitually bolt if grown earlier would then do so but very slightly. Cabbages, however, in June and July, have little attraction compared with the small, firm hearts obtainable in the month of April. Of the forty varieties thus tested at Reading, the few absolutely reliable non-bolters are "April," represented by several hundred of plants, every one having a perfect, firm, white heart; Flower of Spring, having leafage and hearts a little larger than "April," follows quickly, and is a perfect non-bolting stock.

Favourite, a variety equally useful for autumn as for spring sowing, is a capital succession Cabbage; then comes Early Market, Ellam's Early, Imperial, and Early Offenham. These are all reliable stocks, and the plants do not bolt. A former favourite, small, early Cabbage, Little Gem, seems quite left behind in earliness and quality of strain. This illustrates how much may be accomplished in the improvement of stocks or varieties by selection, a practice that is far safer with the Cabbage tribe than is intercrossing. Persistent selection has resulted in getting these early and reliable varieties, and selection still goes on at Reading, for any plant which seems to show advance is marked and induced to flower and seed in due course. Such fine old varieties, so admirable for spring sowing, as Early York, Sugar Loaf, Nonpareil, All-Heart, Heartwell Marrow, Emperor (of the Offenham type), Main Crop, Matchless, Defiance, Early Rainham, St. John's Day, Christmas Drumhead, Winning Stock, the Coleworts, Blood Red, and several others gave from 10 to 60 per cent. bolters; indeed, some, such as the Red Cabbages and Coleworts, had not one that showed true character. Most gardeners know that no plants are more difficult to keep absolutely true to character than are the members of the *Brassica* family. Coarse plants, when found in the seed beds, of recognised non-bolting stocks, should be pulled up and thrown aside. It is well to understand that in all stocks, and especially in those that are highly bred, there is a natural tendency to precocity of flowering.

A. D.

TREES AND SHRUBS.

VIBURNUM CARLESII.

Or recently introduced shrubs this promises to prove one of the best. Figures of the plant have appeared in Japanese plant catalogues and other publications, but it is only within the last twelve months that it has flowered in this country. In 1902 a small plant was received at Kew; this blossomed for the first time in the spring of 1906, and it is now, with one of its progeny, flowering again. *V. Carlesii* is a native of Corea and is quite distinct in general appearance from any other cultivated species. The largest plants at Kew are from 1½ to 2 feet in height, and the same measurement across. The leaves are more or less ovate, 2 inches or more long, with rather conspicuously-toothed margins and covered on both surfaces with a soft pubescence. The flowers develop during May: they are thick in texture, one-third of an inch across, white on their inner surface and pink on the outer. The inflorescence is flat, 2 to 3 inches in diameter, and it bears a strong resemblance to some species of *Rondeletia*. The flowers have a delicious perfume.

Experience seems to show that the species is capable of withstanding any ordinary winter without injury, for entirely unprotected plants in the open withstood the severity of the past winter without injury. It has been found to thrive best at Kew in light loam intermixed with a little peat. Cuttings root readily in the summer, but they are slow of growth for the first two or three years. W. D.

FIG. 137.—A WELL-TRAINED "BUSH" OF BEURRE D'EL PEAR.
(For text see page 326.)

home-saved seed of reputed varieties gave from 60 to 70 per cent. bolters. The assumption was that, as all the plants prematurely flowering showed coarse growth, the seed-bearing plants had been, through the agency of bees or the wind, impregnated with pollen from other varieties. It was specially interesting to note that a second planting from the same seed-bed gave not a single bolter. The inference is that when plants of a coarse or generally strong growth are found in a seed-bed these are the result of cross-breeding, and will flower prematurely, therefore they should be destroyed and not planted. In the second case a variety of high northern reputation gave 15 per cent. "bolters," and every one of these plants was coarse in growth. Here again, a second planting gave no bolters. Possibly it may be said that the earlier planting conducted to the bolting, but if that were so, not 15 per cent. but all the plants would have run to flower.

made on August 10 of forty types or varieties—not an exceptionally early date, and the transplanting of the seedlings was done on October 3. Another interesting feature of the trial was the observance of the effects of age of seed in the matter of bolting. Seeds of three, four, and five successive years' saving were sown and plants from each sowing were planted side by side. No differences were noticed in the matter of premature flowering, conclusive proof that age of seed has no effect in this direction. The primary object of August-sowing and early autumn-planting of Cabbages is to secure hearts, firm, and fit for cutting several weeks prior to the time when Whitsuntide Cabbages are ready. For that purpose there has been bred a race of small-hearting but very precocious varieties, which, planted rather closely together on good soil, produce their small, white and firm heads early in April and onward. Were it desirable to obtain larger heads in June, obviously

THE TRILLIUMS.

THE Trilliums, a small group of American woodland plants, are almost solely represented in gardens by the popular *T. grandiflorum*, the other species being badly neglected as garden plants, despite the fact that many are showy subjects, others are sweetly scented, and all possess some desirable attributes. The Trilliums are very hardy and will thrive splendidly in a rooting medium of peat, leaf-soil, and sand, or the sweepings of country roadsides after it has been stacked for the purpose of killing weeds. They should be placed in the coolest position the garden affords, and be protected from searching winds in March.

With the exception of *T. petiolatum*, which is scarcely worth growing, and *T. Smallii*, a new species (?) from Japan that I have not succeeded in flowering, all the species I am acquainted with are desirable subjects for the rock garden, bog garden, or the informal garden in which water is introduced, or in which cool sites could be made for their reception. It is astonishing what a wealth of flower and foliage Trilliums produce in a cool, rich soil, and once well provided for, they will outlive the planter if occasionally top-dressed and not otherwise disturbed. Shade is desirable where there is lack of moisture, and not otherwise.

SPECIES AND VARIETIES.

T. CERNUUM is a pretty nodding species whose petals are white and measure an inch across, the flower being very fragrant. In all other respects it is a tall, lax *T. grandiflorum*, and inferior to that species as a garden plant.

T. ERECTUM has dark green foliage, purplish stems, and reddish-purple flowers, whose petals are 2 inches across. It exceeds a foot in height when well grown. As a garden plant it is surpassed by its variety *album*, a very pretty plant whose petals are white, tinted with olive, and with a livid red-coloured throat. *T. erectum* is dull in colour and suggestive of an Aroid in its petals and scent, but the variety *album* is showy and refined. In the West of England and Scotland many old-established clumps of the white *erectum* grow out of recognition, yielding flowers as large as those of *T. grandiflorum* on stems 2 feet high.

T. ERYTHROCARPUM is an exquisite little plant that everyone admires. It has attractively spotted ovate leaves in the usual triple arrangement, and showy white flowers that are heavily blotched with crimson at the throat. It is a little difficult to manage, and it enjoys a drier condition of soil than the others. When it has been established for three years it makes healthy clumps 18 inches high, and produces numbers of its solitary inflorescences.

T. GRANDIFLORUM is probably known to every gardener. It throws up clusters of pale green leaves that are bronze-tinted when young, each stem bearing a lonely, nodding, white flower measuring 4 inches across the perianth. As the flower ages a slight suffusion of pink is apparent, and it is at this stage markedly fragrant. It is an accommodating plant and does well in a woodland glade in which is an accumulation of leaf-soil, and it loves moisture in plenty. In cool and sheltered gardens, it reaches a maximum height of 3 feet in the West of England, but in colder counties 18 inches is about the average. One can do much to encourage its growth by choosing for it sheltered corners of a rock garden, or a recess by a woodland walk where winds are tempered. Few plants lend themselves to what is termed "naturalising" better than this Trillium. It is more refined than gaudy, and as such is to be welcomed amongst woodland scenery. Numerous geographical forms are recorded that differ in minor features only. The best and most distinct garden sport is the variety *roseum*, a lovely variation from the type and whose flowers open a blush-pink, deepening in tint to rose ere they fade. I once grew a collected form of *T. grandiflorum* that showed

hybridity with *T. stylosum*: it was midway in structural and colour details between the two species, but it died after flowering, as the result of injury by eel-worm. *T. grandiflorum* and *T. stylosum* are found together in some districts.

T. NIVALE.—This is in appearance a diminutive *T. grandiflorum*, and it flowers as early as March in the vicinity of London. It has short, pure white petals that are lance-shaped and 1½ inches in length. The leaves are ovate, barely raised above the soil, and spotted with purple. The species is adapted to the rock garden, where wind-shelter can be given to it early in the year, and its low habit will accord with its surroundings. It will grow in any soil and does not require the amount of moisture necessary to most of the other species.

T. OVATUM is a dwarf and distinct plant whose three leaves form a complete circle around the stem, and they are produced but an inch or two above the soil. The flower is stout and but little raised above the leafy verticil. The petals are 1½ inch in length, pure white when they first expand, developing a tint of wine-red with age, particularly at the base. Its greatest value is in the rock garden, and it should have the shelter of a boulder for its earliest flowers.

T. RECURVATUM.—This is a singular species, and one whose flowers and leaves are remarkably curved and undulating. It grows to a height of 18 inches, and develops lax, blistered, wavy leaves that are marbled with pale purple on a dark green ground colour, and purplish foot-stalks. The flowers are raised above the leafy verticil as in *T. grandiflorum*. The petals are crimped, much recurved, 3 inches long, lance-shaped, the margins incurve, and they are coloured a ruddy purple, against which the chrome-yellow anthers appear in vivid contrast. The flower is sweetly scented when it first opens, but later is suggestive of *Arum dracunculoides*. It is a plant of curious appearance, and there is a rugged disproportion of its parts that add to its grotesqueness. Nevertheless, it is an attractive species.

T. SESSILE is a quaint-looking plant, whose varieties alone are possessed of real decorative value. The type has broadly ovate leaves in the usual verticil of three, and the foliage is coloured sage-green, with numerous paler green, and purple spots. The flowers are literally composed of three chocolate-tinted straps that arise from the centre of the leafy verticil, which is 5 or 6 inches in height. The inflorescence does not possess much beauty, but the flowers diffuse a delicious fragrance that recalls the odour of *Magnolia Candollei* in the Palm House at Kew.

The variety *T. s. CALIFORNICUM* has leaves spotted as in the type, and white flowers that are claret tinted in their lower halves. Here again a rich fragrance is diffused for weeks around the flowering plant. This variety is very vigorous in habit, and in favoured localities will form a thicket 2 feet through and 3 feet in height, every stem supporting its cluster of leaf and flower. The petals remain for a long time on the plant. Another variety, *T. s. album*, has spotless green leaves and broad petaled flowers with a suffusion of yellow at the base of each petal. It is a very desirable plant. *T. sessile* and its varieties flourish in a bog or marsh.

T. STYLOSUM will grow wherever *T. grandiflorum* thrives, and it has almost equal ornamental value. The flowers, however, are not so large as in that species, the petals being narrower and reflexed, but there is charm in a thriving colony of *T. stylosum*. Its leafage is bronze-tinted when young, becoming dark green with age. The flowers are rose-pink in the majority of cases, but the colour varies considerably. All are beautiful, but all are not alike. I well remember *T. stylosum* growing in the moist leaf-soil of a Cornish garden. Its petals had broadened to such an extent that it was recognised with difficulty. On the east coast of these islands it rarely exceeds a foot in height, but on the west coast 2 feet is the minimum.

Those persons who have moist gardens surrounded wholly or in part by woods will find the Trilliums tractable, easy of culture, and a source of much enjoyment, but in dry or smoky or calcareous gardens they are "a peck of trouble" to cultivate. *G. B. Mallett.*

NOTICES OF BOOKS.

* SEASIDE PLANTING OF TREES AND SHRUBS.
By Alfred Gaut.

No more troublesome problem confronts the gardener and woodman near the sea than the planting of the exposed positions under his care. We have abundant evidence of this in the number of enquiries that reach us on this matter. We welcome, therefore, any contribution to our knowledge on the subject; especially when it is by one who has had so many opportunities of observation, as the author of this book has had. Mr. Gaut has for some time been engaged in giving lectures and demonstrations in horticulture in (among other places) the seaside districts of Yorkshire. Nowhere in England, perhaps, are the conditions generally less favourable to the establishment of an arboreal vegetation than they are on that stormy, wind-swept coast. Success attained in such places may well be regarded as affording a reliable guide for use in any other part of the kingdom. However much local conditions may vary, the leading features of the problem are the same.

The influence of the sea on both climate and vegetation is in itself a beneficent one. We see proofs of this in the wonderful variety of plants which can be grown near the coasts better than elsewhere in the British Isles. This, however, applies to the valleys and sheltered tracts. The problems of seaside planting really only arise where exposed headlands and broad, unsheltered areas are in question. Even then it is not the sea itself, so much as the violence of the winds that come from it, which constitutes the evil. In such positions as these the essential thing is to plant a shelter-belt. When once a permanent screen has been formed, the first great difficulty has been overcome. Often a beginning can only be made by erecting a "dead" fence of some kind—it may be of wood, or stone, or earth—behind which the first plantings can be made. The conditions then become more and more favourable as each successive inland belt is planted.

For these reasons we are inclined to regard Mr. Gaut's chapter on "The first line of exposure" as the most valuable and important in his book. When once vegetation has been established that will bear the brunt of the storm, the choice of trees and shrubs to grow behind the protection thus afforded is much more extended. The list Mr. Gaut gives of such plants might, indeed, be almost indefinitely enlarged. Readers will be more interested to know what subjects the author recommends to plant in the "first line of exposure." This part of the work, which deals not only with the choice of trees and shrubs to plant, but also with such matters as fences, preparation of the soil, and planting, makes the book of genuine value to all who have to confront the problem of seaside-planting.

Mr. Gaut's nomenclature is good and careful. We are gratified to see that he does not perpetuate the old error of calling Spruces "Abies," and Silver Firs "Picea." There is only one error of any importance that we have noticed. This is in reference to the well-known *Lycium*, which is a most useful shrub to plant in the most exposed places by the sea. The author alludes to it as *Lycium barbarum*, which is really a native of North Africa, and, if it exists at all in this country, is exceedingly rare. The shrub to which Mr. Gaut alludes, and which is so frequently seen near towns on our coasts, is *Lycium chinense*. This, however, is not a great matter. The book is a worthy addition to the gardener's library, and it is illustrated from photographs taken by Mr. Frank Sutcliffe.

* Published by George Newnes, Ltd. (Country Life Library), pp. 101, with figs., price 5s.

MARKET GARDENING.

ASPARAGUS-CULTURE IN THE VALE OF EVESHAM.

THE fertile Vale of Evesham is noted as much for its Asparagus as for its Plums, and certainly no crop of recent years has found more favour with growers than the Asparagus. It is no exaggeration to say that the acreage around Evesham under Asparagus is five or six times as great as it was fifteen or twenty years ago, and it is no less satisfactory to record that, despite the increased quantity which is sent to market, the price has not declined, but rather it has improved. A rough estimate by one of the more prominent growers and dealers in Evesham estimates the acreage now under cultivation in the Evesham district at from 1,500 to 2,000 acres, and it is certain that no district in England produces a finer sample. In the borough of Evesham itself very little is grown, the most favoured localities being those round Badsey, Bretforton and Wickhamford, where a great quantity of the vegetable has been planted during recent years. Three or four years ago Badsey suffered very severely from Asparagus blight, but

The illustration at fig. 138 represents a packing shed of a large Evesham firm, who carefully dispatch their Asparagus packed in cardboard boxes. In the tying and arranging of the "grass" women are generally employed, as they are found to be quicker with their fingers and their touch is lighter, a consideration when the delicacy of the "buds" is considered. In recent years much more care has been taken than formerly in grading Asparagus for market, and there is a less tendency to place inferior sticks in the middle of the bundle. With all classes of produce there is a diminution of the reprehensible practice of "topping." H.

THE PROPAGATOR.

WARM-HOUSE PLANTS.

In May, sowings may be made of the seeds of Palms, which should have been previously stratified in a bed of loam placed under the stages or arches supporting the same in a plant stove. Here the seeds are brought by moisture and warmth to the point of germinating, and they will then be ready for placing in the seed pots at an inch or two apart, according to size. The mix-

75° Fahr., and top heat a few degrees higher. The cuttings of the species of Euphorbia make fine potsful if placed to the number of four or five in small 48's filled with the same kind of mixture, striking them in the same degree of heat, and affording one shift into 6 to 8-inch pots when well rooted. The cuttings may also be struck singly in 60's, and afforded a shift into 32's later on.

Aphelandras of species, may be increased by cuttings when seeds are not employed to increase the stock. The cuttings may be rooted at this season, similarly to Poinsettias. Growth having become general with Codæums, Stephanotis, and Hoya, these favourite hothouse subjects may be increased by means of cuttings. No difficulty will be encountered in their rooting if a common hotbed, with a temperature of 70° top heat, and of 80° bottom heat, or a propagating pit with a hot-water apparatus, be used for their reception. In the hotbed-frame no bell glasses are required—indeed, unless the moisture were wiped out of them night and morning they would induce decay in the cuttings—but in the more airy pit or house, bell glasses, hand-lights, or close cases must be provided.

COOL-HOUSE PLANTS.

Cuttings of Fuchsias may be struck on bottom heat in a frame or in the propagating house, and if the house is airtight no further covering is required by the cuttings.

Pelargoniums of the show and fancy sections can be struck in pots, singly (the best plan) or to the number of four to six in 60's without bottom heat, if nearly matured shoots be taken. These and the scented-leaved species from the Cape, when taken in a half-ripened state, may be afforded bottom heat of 70° Fahr. In the mature state later in the year they will not require other than sun-heat in their propagation. Plants of Zonal varieties struck in this month are useful for successional flowering in the autumn.

Chorizemas now strike easily from half-ripened shoots, taken with a heel of older wood, in peat and sand, with a surfacing of pure sand, in warmth of 55° to 60° Fahr. Bell glasses should be used to cover the cuttings.

Take cuttings of young shoots of both Murrillia and Polygala now that growth is active, and see that each possesses a heel of older wood. Remove the lower leaves so far as the cuttings enter the soil. The rooting medium should consist of two-thirds peat and the remaining portion coarse, clean sand. Afford a regular degree of moisture to the soil, and let the warmth be from 55° to 60° Fahr. The cuttings will form roots in about one month from the time of their planting.

OUT-OF-DOORS SUBJECTS.

This is the best season for taking up the Violets that have been grown in frames for supplying flowers, and selecting the strongest runners or offsets for planting out for next winter and spring flowering. If each runner be furnished with a number of young roots, its progress will be rapid, if proper care be taken in selecting the sites of the summer beds, runners picked off, weeds kept down, and red spider kept under by copious waterings and syringing in dry times. Rootless offsets should be saved if stock be required, dibbling them in a shady, moist place; and, if not wanted for frame culture, their offsets, if any, may be left on the parent plants.

The older portions of the plants that have borne blossoms may be thrown away, if not urgently wanted. Prepared young Violet plants in excess of frame requirements make fine floriferous beds and lines in the vegetable garden.

Rare species of Lilies, of which it may be desired to increase the number, should have the flower stems carefully laid on the soil and thinly covered with a layer of leaf-mould, peat, and sand; doing this when the flower buds are

FIG. 138.—ASPARAGUS-CULTURE AT EVESHAM.
(Packing the "grass" for market.)

this has now disappeared, the old beds where it was prevalent having been broken up. The land in these localities is for the most part a stiff, heavy clay, and here the beds will stand and bear well for as long a period as twenty years. Some of the land which is now carrying remunerative crops of Asparagus and Plums was a few years ago worth very little for ordinary farm purposes, and tenants could not afford to pay the small rents then charged.

This year the persistent cold weather has retarded the crop greatly. The lateness of the crop may not, however, prove a bad thing for the growers, for if it developed in bulk early it would have to compete with the foreign article, with a consequent reduced price. Although most of the private consumers will have English Asparagus if they can get it, the hotel and restaurant-keepers purchase the cheaper article, and, after all, these are the people who take the bulk of the crop. It is probably a fair computation to say that Asparagus ranging in weight from 3½ lb. to 4½ lb. per bundle (which includes 120 buds) will average all through the season as much as 1s. 9d. per bundle.

ture that best suits the plants consists of two-thirds loam and one-third leaf-mould, and sufficient sand to afford porosity. The drainage material should be sufficient, but not excessive in quantity. The seeds of Cycads and Bromeliads may be sown at this time in a similar mixture, in pans or shallow pots, and at about their own depth in the soil, placing the seed pots, &c., in a warm pit or hotbed-frame, having a top heat of 70° Fahr. The spores of exotic Ferns may now be sown in pans or on thick tiles partially immersed in a pan of water, a ready mode of getting these extremely minute spores to vegetate, and it obviates the use of the syringe or watering pot, which, unless used most carefully would wash away or displace the spores. Vinca rosea, V. oculata, &c., when raised from seeds sown in heat in May, make useful little subjects that flower in the autumn following. Cuttings of both Poinsettia pulcherrima and Euphorbia jacquiniæflora may be inserted, the former in hard peat two parts and sand one part, in pots placed under bell glasses or hand-lights, affording them a bottom heat of

appearing, and removing all of these that can be detected. This will cause bulbils to form in the axils of the lower leaves.

SEEDS.

In prepared beds in a part of the garden enjoying sunshine for half of the day, seeds may be sown thinly and regularly broadcast, of Pansies, Antirrhinum, Stocks, and Wallflowers for spring flowering, and of many kinds of hardy perennials and biennials. The seeds will germinate more regularly if they are covered with rich soil, sifted over each bed or patch in quantity commensurate with the diameter of the seeds. This plan of seed sowing is for most things better than drills, hoeing-in, or raking-in, as obviously the depth to which the seed is buried is more regular. If the weather is showery, the seeds will be securely covered; otherwise, a slight firming with the spade or a smooth piece of board is called for in all but the heaviest kinds of land.

The seeds of the Chinese Primula may now be sown for early winter flowering, employing a mixture of equal parts peat, leaf-mould, and loam, together with a moderate amount of sand. If new seed pans are used for this sowing, let them be well soaked before putting the compost into them, or many seeds near the sides will, from alternating dryness and wetness in the mould, fail to grow, or put forth only a crippled growth. Until vegetation takes place, a warm bed is the best place for the seed pans, at once removing them to a cold frame on the cotyledons appearing above the surface. *F. M.*

The Week's Work.

PLANTS UNDER GLASS.

By J. G. WESTON, Gardener to H. J. KING, Esq., Eastwell Park, Kent.

Campanula pyramidalis.—Seeds of this attractive Campanula should now be sown in pots or pans of light, sandy soil, placing them in an atmosphere of intermediate temperature. As soon as the seedlings are of sufficient size to be handled conveniently, prick them out into pans or boxes, and place them in a cold frame. They should subsequently be potted up singly. After they have recovered from the check caused by the potting process, place the plants outside on a bed of ashes, re-potting them when required into strong, loamy soil. In winter, during severe weather, the plants will need the protection afforded by a frame. Do not coddle them, but, unless they are wanted in flower early for any particular purpose, let them be placed outside again early in April. At the present time last year's seedlings will be throwing up strong flower-spikes, and they should be afforded occasional top-dressings of manure, also plenty of water, as the pots are filled with roots. Secure the flower-spikes by tying them to stakes, as they are liable to get damaged by winds. Remove the plants to a position under glass as soon as the flowers begin to expand. The strain known as "compacta," raised at Syon House, is excellent for use in company with the taller-growing varieties.

Bouvardias.—Keep the young plants growing in an intermediate degree of heat, pinching the points out of the shoots occasionally to induce a bushy habit, and repotting the plants, when necessary, into a compost consisting of equal parts turfy loam and leaf soil, and some sand. The old plants which were cut back early in the spring should also be potted on, unless the planting-out system is practised, and this is successful in warm localities. If the latter plan be preferred, select a sunny and sheltered position on a south border for planting early next month, or, better still, a frame, where the plants could have the benefit of the glass to give them a start, dispensing with the lights altogether when they have become established. Pinch the shoots once or twice, but not too late in the season, and syringe the plants frequently in hot weather. These will require to be lifted and potted in September, cutting round the ball carefully with a sharp spade about a week previous to the lifting. After potting, water the plants thoroughly, and place them in a shady position for a few days until they have sufficiently recovered from the check, when they may be gradually accustomed to full sunshine again.

General work.—Seeds for the main batches of Primulas and Cinerarias should now be sown in sandy soil, which should be moistened with water before sowing the seed. Place the pots in a cool house or frame, and keep the soil uniformly damp, as dryness in the seed pan is often fatal to the germinating power of small seeds. Plants raised from the earlier sowings will now be ready for pricking off, after which they should be returned to the frames, placing them near to the glass and slightly shading them in bright weather.

THE FLOWER GARDEN.

By A. C. BARTLETT, Gardener to Mrs. FORD, Pencarrow, Cornwall.

Bedding-out.—Before starting any work on the flower beds which are set in grass, let the lawn mower be run around them and the edges be clipped. Plenty of planks should be ready to hand in order that the grass may be preserved. Those beds which are occupied with spring-flowering plants are mostly ready to be cleared. The Wallflowers may be consigned to the rubbish heap. Such plants as Aubrietias, Arabis, and Alyssum saxatile, after lifting, should be split up into small pieces and planted in rows in the reserve garden. If given proper care and attention, they will provide good plants for use next autumn. Should the weather be hot and dry before the plants have recovered from the check of removal, let branches of Beech tree be stuck in the ground between the rows to shade them, and the plants be sprayed with water towards the end of hot afternoons. London Pride (*Saxifraga umbrosa*) and Primroses are amenable to similar treatment. Bulbs should be carefully lifted, bestowing especial care upon those whose foliage is still green, or partly so, planting them in a fairly sunny spot, and labelling them. When two sets of plants follow one another in such quick succession as they do in the flower beds, deep digging is essential. As was directed in previous calendars, each bed will need to be "dressed" according to the kind of plant that will be planted in it. The Wallflower is such an exhausting plant that the beds in which they have been growing should receive an extra amount of manure. It is an excellent practise to mix a good quantity of bonemeal with the top foot of soil just before planting is done. The soil should be lightly trodden and raked level. Should hot sunshine prevail it will be wise to defer planting work until three or four o'clock in the afternoon, and, under these conditions, it will do good to give the beds a good watering as each is finished, having previously cleared away all empty boxes or pots and made up the edge of the bed and swept the grass clean. As suggested for the reserve garden, the beds may be lightly shaded with tree branches.

Annuals.—The seedlings from the first sowing out-of-doors are now in a fit state for thinning. This should be rigorously carried out, for it is better to slightly err in allowing too much room than too little. After the thinning has been done, hoe between the rows, and if slugs are suspected dust the plants with soot.

Border Carnations should be lightly tied up to slender stakes of a neutral colour. A dressing of any approved artificial manure will greatly assist flower development.

THE HARDY FRUIT GARDEN.

By J. MAYNE, Gardener to LORD CLINTON, Bickton, East Devon.

Cherries.—A minute examination should be made on each tree for the destructive black aphid, and even if none is found, it is advisable to give the trees a dressing with Quassia extract, as previously recommended for the Peach. A tiny black maggot also attacks the young growths of the Cherry, and soon cripples the points of the shoots, and often injures the branches that are required for training in as the fruit-bearing wood for next year. These maggots curl themselves in the leaves, and hand picking is the best remedy. Disbudding of the Morello, especially trained trees, should be practised more frequently than it is, as these trees produce far more shoots than are required, and the removal of them later in the summer by cutting is detrimental to the ripening of those shoots from which will be formed the bulk of next season's crop. Shoots on the face of the branches and next the wall are those that should be first removed, retaining

any on the sides of the fruiting wood, as in the case of the Peach and Nectarine. The removal of these superfluous growths may be done as soon as they develop, but care must be taken that the young fruits are not removed with them. Leading shoots need no stopping, save in the case of those that will be cut out at the winter pruning. Any young wood approaching grossness and likely to cause weakness in other parts of the tree should be pinched quite early. Trees growing in hot, dry positions should have a layer of about 1½ inches of partly-decayed manure placed over their roots, extending it to a space of 4 feet or more from the stem of the tree. While the above remarks are intended for the Morello, they are, in a lesser degree, applicable to other Cherries.

Mulchings.—Before applying a mulch of any sort the surface soil should be lightly forked. Early mulchings are highly beneficial to Pears and Apples growing on the Quince and Paradise stocks respectively, and on light, hungry soils it would be well to cover the manure with a little soil so as to retain the manurial elements for as long a period as possible. All weeds—and there is a host of them this spring—must be removed before these manures are applied.

Fruit prospects in this locality are particularly good. Peaches, Apricots, Plums, Cherries, Gooseberries, and Currants are all carrying good crops of fruits, and several varieties of Pears are well fruited, but many of these latter fruits drop towards the end of May owing to the Pear midge. Strawberries and Raspberries promise well.

THE KITCHEN GARDEN.

By WILLIAM H. HONESS, Gardener to C. COMBE, Esq., Cobham Park, Surrey.

Peas.—There have been even greater improvements made in raising new varieties of dwarf-growing and early-fruited Peas, than in main-crop varieties, for it is only a very few years since the early-fruited section consisted almost entirely of white and round seeded varieties. Some of the newer varieties are approaching the later fruiting type very close in regard to colour, size, and flavour, and it is a difficult matter indeed to particularise any one or two varieties. Little Marvel, that was sown in boxes in November and planted out in a late Peach-house in February, is now carrying a good crop of well-filled pods. Our first picking was made on the 18th inst. Closely following is Green Gem, that was sown about the same time in a cold frame, and these will be ready about the 28th inst., after which date the varieties already mentioned will be yielding on the outside borders. These are well "backed up" by crops raised from successional sowings, therefore a continuous supply will now be maintained throughout the summer. Continue to sow seeds of good main-crop varieties, which must soon be followed by later sorts, including the Gladstone, Alderman, and Autocrat, the last-named Pea being a splendid main-crop variety for cultivation during a dry season.

Potatoes.—Old tubers are fast deteriorating in quality, and they should be thoroughly examined and picked over, rubbing off any growths they have made. Although this work will occupy much time, it is a most necessary proceeding, for, if allowed to make roots or top growths, the tubers soon get "sweet" and are unfit for cooking purposes. There must yet elapse a considerable time before new Potatoes will be anything like a general supply. A close watch must still be kept on Potatoes pushing through the ground, drawing the soil up to them each day, for it is not yet too late in the season for frosts to injure them.

Marrows.—Plants raised from seeds sown early in the season and that have been grown in heat as advised in previous calendars, should now be giving some returns. If the yield is not great, at the same time the Marrows at this time of the year are very useful in making a little change. Later plants, to provide the main supply, should now be planted in cold frames, or under hand lights, on prepared beds, the bush form being very useful, as it can be grown in a more limited space. Plants of the varieties that are being hardened, may also be planted in the open, giving them a little protection at night if frost appears likely to occur.

Salads.—Frequent sowings of the various salads should be made, as during hot weather, unless plenty of water can be applied, many plants will "run" to seed very quickly.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower to Sir TREVOR LAWRENCE, Bart., Burford, Surrey.

Cattleyas.—Plants of *Cattleya Mossiae*, *C. Mendellii*, *C. Schilleriana*, *Lælia purpurata*, *L. tenebrosa*, and hybrids of these species that are showing their flower buds will require a little more water at the root until the flowers are fully expanded. *C. Bowringiana* is still dormant, but so soon as growth recommences the plant should be placed at the warmer end of the house, and be gradually accustomed to copious and more frequent supplies of water at the root. The distinct *C. Lawrenceana* is also now at rest, having just passed out of bloom. I was recently informed by a competent authority, who has visited the *C. Lawrenceana* district on several occasions, that the plants grow at an altitude of about 3,000 feet above sea level, where they are fully exposed to the sunshine. The temperature at night averages at about 60°, and during the day 75°. I was advised that while the plants are at rest they should be placed in a warm and light position in the *Cattleya* house, and be kept fairly dry at the root, a slight shrivelling of the pseudo-bulbs doing no harm. During the growing period a similar position in the cooler atmosphere of the intermediate house will be more suitable.

Thunias.—The different varieties of *Thunia* will now have their flower buds well advanced, and if it is desirable to propagate any of them, now is the best time for the operation. Take off the back growths, cutting them at the joints into lengths of about 6 inches or 8 inches, and inserting them firmly as cuttings into well-drained pots, using a mixture of sphagnum-moss and coarse sand. Place them in a dry position on a shelf in the warm house, and spray them frequently with water. When the young shoots appear grow them on as quickly as possible, but do not disturb the plants by repotting them, until next spring.

Calanthes.—Such evergreen species as *C. veratrifolia*, *C. masuca*, &c., that require repotting, should be attended to soon after the plants pass out of flower. Being strong-growing, free-rooting plants, they require rather large pots, which should be made one-third full with drainage material, placing over this a thin turf with the grass side downwards. A compost consisting of fibrous loam three-fourths and leaf soil one-fourth will be suitable for use, if some broken crocks and silver sand be mixed with it. Make this compost moderately firm about the roots and leave a good space on the surface for water. For some time only small quantities will be needed, but as the growths develop and roots become numerous, the supply should be considerably increased. Place the plants in a shady corner of the *Cattleya* or intermediate house, and keep them down upon the stage, as they do not succeed so well if the foliage is near to the roof glass. The cooler-growing varieties as *C. japonica*, *C. j. alba*, *C. discolor*, *C. citrina*, &c., may also be repotted at this time. Pot them in the same mixture and give them plenty of root-waterings from the time they commence to grow. Brown scale is sometimes very troublesome to these *Calanthes*. The pest must be eradicated by timely sponging, and by employing the usual vaporising process.

FRUITS UNDER GLASS.

By ALEXANDER KIRK, Gardener to J. THOMSON PATON, Esq., Norwood, Alloa, Clackmannanshire.

The vinery.—Black Hamburg and Madresfield Court Grapes in late houses will now be ready for their first thinning. Begin by carefully tying up the shoulders of the bunches with thin strips of matting, and always commence the thinning at the point of the bunch, and work upwards. Remove all small berries. Maintain a warm and humid atmosphere in the house at this stage of the vine's growth, and close the structure early in the afternoon. Damp the paths and the borders once in the morning and again in the afternoon. The night temperature should be maintained at 65° Fahr.—the day at 85°. Admit air early in the morning as soon as the temperature rises to 70°. If the weather is mild, allow a little air to enter through the top ventilators; this will prevent the bunches growing too loosely, a condition of growth favoured by excessive heat and moisture. Test both the inside and the outside borders, and if they are dry, give a good soaking with warm manure water.

Muscat Grapes, that have just finished their stoning, will require very careful attention, as they are liable to scalding at this stage. If the weather is hot, let the ventilators of the house be opened more freely. If any signs of scalding is noticed, lower the day temperature of the house to 80°, and keep the night temperature at 70° with the aid of the hot-water system, but close the valves in the morning. Open the top ventilators a little at night time, and admit air freely in the afternoon. Reduce the amount of moisture, for a high, dry temperature at night time, with a cooler and dry atmosphere by day, is the best treatment to prevent scalding. When the fruits of later vines, including *Lady Downes*, *Alicante*, and *Gros Maroc*, have set, the temperature of the house should be lowered to 65° at night and to 80° by day. Damping should be resumed to maintain a moist atmosphere. Admit air by the top ventilator only, and apply the ventilation early in the morning. It will now be necessary to thin the bunches on each vine, leaving always the best and the largest, but preserving a few more than are required for the crop; these extra bunches can be removed later. Pinch and train in lateral shoots where space exists for them. Be on the watch for red spider, and should any be found sponge the leaves at once with soft soap and hot water, on both sides. Should this pest become in the least established, syringing must be resorted to every afternoon.

Tomatos.—The different batches of these plants are now making good growths, whether planted in pots, boxes, or in borders. Stop the leading shoot by pinching the point out of it as soon as it has grown to a desired height. Rub out all lateral shoots as soon as they appear. Afford manure water to any plants on which the fruits are swelling. Maintain a dry, airy atmosphere in the houses, and admit a little outside air at night-time. The temperature by day should be 70°; by night, 60° to 65°.

PUBLIC PARKS AND GARDENS.

By W. W. PETTIGREW, Superintendent of the Parks and Open Spaces in the City of Cardiff.

Aquatic weeds.—One of the greatest difficulties to be faced in the proper maintenance of ornamental sheets of water, is the destruction of the aquatic weeds with which such waters are apt to become overgrown. Where it is deep, little trouble as a rule is experienced, but in still waters, such as those in lakes, ponds, and canals, numerous sorts of weeds will grow to the surface, even from a depth of 7 to 8 feet. Where lakes or ponds are used for the purpose of bathing, boating, fishing, or model yachting, it is very essential to get rid of such plants as *Myriophyllum*, *Potamogeton*, and aquatic forms of *Polygonum*, or, at the very least, to keep them a good distance below the surface. How to do this satisfactorily, and at the same time economically, is a question which requires much consideration.

Cemented base.—The remedy often recommended in the case of small ponds is the construction of a concrete bottom, but even then such plants as *Spirogyra* and similar water weeds—which require no rooting medium—very often make ponds of this description quite as unsightly as those which require a natural soil bottom. Even vascular water plants soon infest a pond where sediment has commenced to collect on the cemented bottom, so that the use of this material cannot be regarded as a cure for weedy ponds.

Use of rakes.—In large ponds and lakes, weeds are often destroyed by being dragged out by means of iron rakes used from flat-bottomed boats. This at best is a most unsatisfactory method of dealing with them, because a large percentage pass safely through the teeth of the rake, and are left undisturbed; also, the stirring up of the mud at the bottom, which must inevitably take place in attempting to get out the weeds, is exceedingly detrimental—especially in hot weather—to such fish as trout, should they be present in the water.

Cutting with scythes.—Cutting the weeds from boats with scythes is another plan sometimes adopted, and although much cleaner than the "raking-out" process, it is too tedious to be recommended for general use—especially where a large area has to be treated.

The best method.—The very best and cheapest method of keeping down aquatic weeds with

which I am acquainted, is one invented by a gentleman in the Isle of Wight. The process enables one to cut the weeds at a given depth below the surface of the water. This is effected by means of a semi-circular, double-edged knife, connected to a long iron bar and affixed to the stern of a flat-bottomed boat. By means of a handle attached to the iron bar, the knife is moved with a circular motion, and when it comes in contact with the stems of the weeds, they are cut, and being detached from their roots float to the surface. The knife blade is so arranged that it can be lowered nearly five feet into the water or raised to within an inch of the bottom of the boat. The boat can be rowed to and fro in parallel lines (similar to the method adopted with a mowing machine in mowing a lawn), and the whole area of a lake or pond may be cleared of weeds in a very short time. After they are cut they can be collected in a barge and carted off to the manure heap, and when completely rotted they will be available for use upon the land.

The process is analogous to the mowing of grass, and, like that operation, it has to be undertaken several times during the season. As soon as the temperature of the water begins to rise in spring, aquatic weeds commence to grow. It is necessary to start cutting sufficiently early to keep the weeds from coming near enough to the surface to interfere with any of the sports or pastimes for which the water may be used.

THE APIARY.

By CHLORIS.

Queen wasps.—These undesirable insects may often be found in the warm quilts over the brood chamber, and a sharp look-out should be kept for them there.

Preparing for the honey to flow.—It is the common practice of beekeepers to put off getting ready until the honey flow is in full swing. Last year two neighbouring beekeepers, with equal opportunities, may be cited as examples of preparedness and unpreparedness. The one who was prepared and whose colonies were not so strong, got over 100 lb. of splendid honey fit for any show table, whilst the other got nothing, for there was only an early flow, the later one being a complete failure. How, then, can we be ready? Have all the shallow frames fitted up and ready to pop on as soon as the tops of the combs in the brood chamber are showing white cappings. If some drawn-out combs are at hand, so much the better. Perhaps some beekeepers may not use shallow frames, but it will pay them to put these on first, for sometimes bees will swarm, sooner than work in sections.

Preparing sections.—When this task is delayed until the last moment, many broken corners result, and a consequent loss of temper attends it. Take a number of sections in the flat and well wet the joints with a good supply of boiling water, piling them one on the other to make them retain their moisture, and when the wetting process is complete overturn the pile so that those first moistened may be used first. Whilst the corners are soaking you may, with great advantage, cut the foundation, which should be "extra thin weed," and may easily be done by aid of a piece of wood cut as a gauge. Cut full sheets, for it is no advantage to use starters; much valuable time is lost, which would more than pay for the full sheets. Fold the sections quite square, for nothing looks worse than ill-folded sections, and let the foundation protrude half-inch above the top, if split top sections are favoured, and leave a space at the bottom to allow for stretching. The foundation should fit well at the sides and be quite secure at the top. If the section has no "split top," a little glue will secure the wax as firmly as anything, but there must be neatness, or the sections will present a messy appearance. If these points are attended to, the sections will fit well in the rack, and will be well filled, so that each one will weigh a full pound. See that the sections are pressed tightly up and separated by dividers. If any spaces are left they will be filled with propolis, and consequently provide more work when they are being prepared for sale. When putting on sections, do not forget to wrap them up warmly, both above and around the sides, and if a sheet of brown paper be placed between the quilts, it will aid materially in keeping up the necessary temperature.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Special Notice to Correspondents.—The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY, MAY 27—Annual meeting and dinner of the Kew Guild at Holborn Restaurant. Dinner at 7.30 p.m.

TUESDAY, MAY 28—Roy. Hort. Soc. Sh. in the Temple Gardens, Thames Embankment (8 days).

WEDNESDAY, MAY 29—Annual meeting of Brit. Gard. Assoc. at Essex Hall, Essex Street, Strand, 7 p.m. Public Conference after the annual meeting.

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich—56° F.

ACTUAL TEMPERATURES:—LONDON.—Wednesday, May 23 (6 P.M.): Max. 44°; Min. 59°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—Thursday, May 23 (10 A.M.): Bar., 29° 7'; Temp., 61°; Weather—Cloudy.

PROVINCES.—Wednesday, May 23 (6 P.M.): Max. 56°; London; Min. 46°; Scotland N.

SALES FOR THE ENSUING WEEK.

TUESDAY—Duplicate Plants from the "Oakwood" collection of Orchids, at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 2.80.

WEDNESDAY—140 Rare and Magnificent Orchids, at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 2.

THURSDAY—500 Imported *Odontoglossum crispum*, 150 Hybrid *Cypripediums*, 50 Imported *Phalenopsis*, and various valuable *Odontoglossum crispums*, at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 1.
Choice Ferns, Geraniums, Carnations, Begonias, Pansies and other plants, also Palms and Standard Bays, at 12; 100 dwarf and rare Japanese Trees and Flowering Shrubs at 8, at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

FRIDAY—The Freehold Fruit Farm and Market Garden, with two Farmhouses, Cottage, Buildings, Greenhouses, &c., 87 acres; Fruit in all about 185 acres, by Protheroe & Morris, at the Mart, Tokenhouse Yard, E.C., at 2.

A plant, or for the matter of that **Adaptation.** any living creature, is the result, as regards its form, appearance, and endowments, of two tendencies, the one which it inherits from its ancestors, the other consequent upon its power of adapting itself to the varied circumstances of the present. The ancestral form may have originated, and probably did so, from like causes, but that was so very long ago that in practice we may disregard it. A botanist engaged in comparing and classifying the plants he meets with, more or less unconsciously places more reliance on what he supposes to be hereditary characters than he does on those which are obviously the result of adaptation to circumstances. The former are relatively permanent, the latter are fluctuating. The general conformation of a Primrose flower, for instance, was evolved so long ago, that despite minor variations of size and colour in the different species, no one accustomed to study plants has any difficulty in recognising the genus *Primula* from the flower. The case of the foliage is different. Primroses of one sort or another grow in all sorts of situations, in different climates, on different soils at varied elevations and aspects.

Leaf action and root action, and all that is implied in those words, must be correspondingly varied and the forms of the plant and leaf diversified accordingly. We may note this by comparing the vegetation on a wind-swept down, in a sheltered wood, on a dry road-side, on a sandy dune, and in a moist meadow by the river. Sea-side plants afford marked instances of adaptation of form and structure to circumstances. Succulence of foliage is a very common attribute in such plants, as witness the wild Beet, the Cabbage, the Sea Kale, the horned Poppy (*Glaucium*), the so-called Tea tree, *Lycium chinense*, all of which, when growing near the sea, have fleshy leaves with thick rinds to prevent undue evaporation, and an increased amount of storage room for water provided for by the inordinate development of the cellular tissue. What precise part the salt plays, independently of other conditions, is doubtful, but evidently its influence is great. The illustrations (figs. 139 & 140) afford good examples of the effect of circumstances on plants. The leaf represented

FIG. 139.—A SUCCULENT LEAF OF THE COMMON PRIMROSE, WITH SECTION.

is that of a Primrose, growing not by a "river's brim," but on the shore close by the Corbière lighthouse in Jersey. The Rev. H. E. Fox, who gathered them and sent specimens to Mr. F. J. Hanbury, describes them as growing in little crannies of soil among the rocks where the men had doubtless planted them. There were several dozen plants all showing the same hypertrophied condition of the leaves. Some of the leaves were sent to us by Mr. Hanbury, and Mr. Chittenden was obliging enough to examine them microscopically for us, and to him we are indebted for the drawings which accompany this note. A section of an ordinary leaf is shown drawn to the same scale for the purposes of comparison. It will be noted that the wrinkled appearance of an ordinary Primrose leaf is replaced by a smooth surface, that the hairs which are so characteristic of a Primrose leaf are deficient, and that the cells of the substance of the leaf, whether of the closely set palisade variety, or the more loosely disposed spongy tissue, are not only increased

in size but in numbers also. Both surfaces have stomata present, instead of the lower surface only.

Many of our culinary vegetables have been derived from seaside plants, and it becomes a question whether the Primrose might not be so modified as to furnish a new vegetable for the table! Primroses are so beautiful and so fraught with delightful associations that we feel we owe them an apology for making such a suggestion, but they would at least serve a more useful purpose if they were employed in this way than when utilised as a badge by party politicians!

OUR SUPPLEMENTARY ILLUSTRATION.—For the illustration of *Plagianthus Lyalli*, an attractive malvaceous shrub, we are indebted to Earl ANNESLEY, in whose grounds at Castleweilan, Ireland, it proves hardy, as indeed it does at Kew. When grown against a wall the young shoots are apt to get injured by sun-scorch. The shrub is a native of the Middle Island of New Zealand, and is well figured in KIRK'S *Forest Flora of New Zealand* (1889), p. 279, tab. cxxxiv. The author describes it as one of "the most graceful and beautiful flowering trees in the New Zealand flora; its large, white flowers, nearly an inch in diameter, are produced in vast profusion and harmonise beautifully with the foliage, which is at once soft in character and bold in outline." It is one of the few deciduous trees of the island, its foliage assuming vivid colouring in the autumn. At low levels the tree retains its leaves in winter. The inner bark is tough and net-like, whence the popular name of Lace Bark. It is illustrated in Earl ANNESLEY'S work, *Beautiful and Rare Trees and Plants*, which contains seventy reproductions from photographs taken at Castleweilan by Lord ANNESLEY himself. Mr. E. G. BAKER, in his synopsis of the Malveæ in the *Journal of Botany* (1892), p. 137, refers this to *Gaya* under the name of *Gaya Lyalli*, the distinction of the two genera being founded on the stigmas, which are linear in *Plagianthus*, but truncate or capitate in *Gaya*.

EVENTS OF THE FORTHCOMING WEEK.—Gardeners are about to enter on what usually proves to be one of the busiest weeks in the whole course of the horticultural year.

On Monday evening the members of the Kew Guild will assemble at the Holborn Restaurant for their annual meeting, and this will be immediately followed by the annual dinner. The president at the dinner will be Mr. GEORGE MASSEY, whose work in connection with the fungus diseases of plants is thoroughly well known to the horticultural public, as well as to Kew men in particular.

On Tuesday morning the "Temple" Show of the ROYAL HORTICULTURAL SOCIETY will be opened in the gardens of the Inner Temple on the Thames Embankment, and conspicuous as previous successes have been, the approaching exhibition is expected to be better and more interesting than ever. The judges of the various groups will commence their work of adjudication at 10.30 a.m., and at 11 o'clock the members of the Floral and Orchid Committees will assemble for the consideration of novelties, of which visitors to the "Temple" Show have usually the opportunity of seeing a considerable number. At 12 o'clock noon a Council meeting will be held, and at 12.30 the exhibition will be open for the inspection of Fellows. It will be noted that the Fruit and Vegetable Committee will not meet on this occasion. The "Veitchian Cup," which has already been awarded at three Temple Shows, is this year reserved for amateurs. Until the present time,

Supplement to the "Gardeners' Chronicle."

PLAGIANTHUS LYALLI, HARDY SHRUB
FLOWERING AT CASTLEWELLAN.

Temple Press Ltd., Printers, 7-15, Rosebery Avenue, London, E.C.

it has been given in each instance to trade growers. We may point out in connection with the "Temple" Show, that since the last one was held in the Temple Gardens, the L.C.C. electric cars have been established on the Embankment, and visitors will find these cars a convenient means of conveyance either from Blackfriars Bridge on the one hand, or Westminster and Waterloo Bridges on the other hand.

The Temple Show will remain open until Thursday evening. The prices of admission for the general public are: Tuesday, 7s. 6d.; Wednesday, 2s. 6d.; and Thursday, 1s. Gardeners can obtain 2s. 6d. tickets for 1s., but these privilege tickets will not be issued later than May 25.

On Wednesday, at 7 p.m., the BRITISH GARDENERS' ASSOCIATION will hold its third annual meeting at the Essex Hall, Essex Street, Strand (close to Temple Gardens). Mr. W. H. DIVERS, head gardener to His Grace the Duke of Rutland, at Belvoir Castle, will preside. After the business meeting is over, a Conference will be held, at which the following papers will be read and discussed, viz:—"Testimonials," by Mr. A. C. BARTLETT, of Pencarrow; "Apprentices," by Mr. W. DALLIMORE, of Kew; and "Examinations for Gardeners," by Mr. C. FOSTER, of Reading University. We believe that satisfactory progress will be reported at this meeting. The association has more than 1,050 members, it has accumulated a capital of nearly £300, and is now publishing a journal.

In addition, "Temple" Show week will be taken advantage of by numerous traders and private collectors for the sale of duplicate and surplus stocks of Orchids. These sales are referred to in our advertising columns.

SOUTH-EASTERN AGRICULTURAL COLLEGE.

—We are informed that a donation of £50 has been made to the College by the Goldsmiths' Company. In the recent examination of the Surveyors' Institution the following students qualified for the Professional Associateship:—Hon. J. M. CAMPBELL, R. N. DOWLING, W. H. A. FITZROY and A. V. SPENCER. The National Diploma in Agriculture has been obtained by A. D. MCKINSTRY, and the first part of this examination has been passed by R. H. CARTER, L. R. EIZAGUIRRE and W. N. HARVEY.

AGRICULTURAL EDUCATION.—The Departmental Committee, of which Lord REAY is chairman, held meetings on the 14th and 15th inst. Representatives of the Ridgmont Agricultural Institute, Bedford, and the University College, Reading, attended and gave evidence.

GRAFT HYBRIDS.—These singular results of grafting have received additions in *Cratægus-Mespilus* Dardari, and C.-M. Asnieres, which originated on the nurseries of Simon Louis Brothers, in Plantieres. One form—C.-M. Dardari—partakes more of the characteristic features of the *Mespilus Germanica*, and C.-M. Asnieres, those of the *Cratægus monogyna*. An illustration in *Die Gartenwelt* shows a plant having growing upon it the two forms of *Cratægus Mespilus* and the typical form of *C. monogyna*. A case in which are combined the forms of the two parents and of the two bastards at the same time, has, Mr. C. K. SCHNEIDER observes in a note accompanying the figures, never before been remarked, but is one that is very probable.

ODONTOGLOSSUMS AT PITTSBURG.—As we learn from the journal *Horticulture*, published at Boston, Mass., Columbian Orchids, of which *Odontoglossums* form the finest section, are likely, should the summer prove a hot one, to have a difficult time. In Dr. SHAFER's collection in that city, in consequence of the many dull, dark, and foggy days during the late winter, there is a general absence of the bronzy tint, the leaves being quite green. The per-

centage of flowers, however, has been good, many plants flowering for the first time, and some of them being plants of the real Pachot type. The collection contains some plants imported in 1895. This puts aside the theory that it is impossible to keep a collection without decrease for a considerable number of years. The doctor keeps an accurate record of every plant which comes into his possession, and it is interesting to note that there have been scarcely any deaths amongst the *Odontoglossums*, although many of them were in bad condition when received. The plants are wintered in a span-roofed house, running north and south. From March till September they are placed in a house especially constructed for cool Orchids. This house has a lean-to roof built against the eastern wall of the *Cypripedium* house, and is shaded on

FIG. 140.—TRANSVERSE SECTION OF A SUCCULENT PRIMROSE LEAF, WITH SIMILAR SECTION OF NORMAL LEAF FOR COMPARISON. THE SCALE REPRESENTS $\frac{1}{5}$ M.M.
(For text see page 332.)

the south by the projecting dome and front of the centre house. Owing to the construction of the range, which is built on the side of a hill, the floor of the cool house is 9 feet below the level of the other compartments. In summer the house gets only the morning sun, being, during the hottest part of the day, quite in the shade of the other houses. Bamboo shading is used to protect the plants from direct sunlight, but this is only needed in the early part of the day. The fact that the range is built on a hillside is a distinct advantage in ventilating, as the lowest ventilators are considerably above the ground level in front.

ROSES PROOF AGAINST MILDEW IN AUSTRALIA.—The Rose suffers from mildew in parts of Australia just as is the case at home. But a good many fine varieties are proof against the fungus, of which a correspondent at Moonee Ponds, Victoria, sent a list to *The Journal of Horticulture of Australia*, which was published in the issue for April 1 last. These are Anna Olivier, Papa Gontier, Maman Cochet, Princess Alice de Monaco, Corallina, Mad. Dupuy Jamin, Marques de Aledo, Mad. E. Metz, Mad. Auguste Chontet, General Schablikine, Mad. Vermorel, Boadicea, Mrs. B. R. Cant, A. Marie Soupert, and Françoise Crouse.

POPULAR NAMES RESULT IN CONFUSION.

In *The Florists' Exchange* is a note on the uncertainty of the names of coniferous plants in the U.S.A. In the southern states the so-called Yellow Pine is *Pinus palustris*; further north it is *P. mitis* (*P. echinata*), and in the northernmost states the term is given to *P. rigida*. Christmas trees consist of *Pinus palustris*, plants 2 to 8 feet high being set in pots. The chief beauty of this plant consists in its magnificent, long needles. *Pinus rigida* is called Pitch Pine, which really and properly belongs to *P. australis*, which supplies the greater proportion of the wood employed in constructing glasshouses. In the older dendrological works we find the names Pitch Pine and Yellow Pine applied to *P. ponderosa*, a proof of the unreliability of folk names.

ROSE PENELOPE.—This is described as a beautiful new Tea Rose, which originated from seed with JOHN WILLIAMS, Broadwater Nurseries, Mount Gravett, Brisbane, Queensland. It is a free bloomer; each bloom is carried singly on long stalks, supported by prominent guard leaves. The flowers are unusually firm and of good substance. The lower half of the flower deep reddish crimson, the centre creamy white, and underneath the centre petals it is flushed with crimson. It is a distinct break in colour from any known variety, and is the first Australian rose to obtain a certificate of special merit from the Royal Horticultural Society of Victoria. It has passed into the hands of a New York nurseryman for distribution outside of Australia.

HYBRIDISATION AND CROSSING IN ORCHIDS.

—In a series of articles that has been running for several weeks recently in Möller's *Deutsche Gärtner-Zeitung* a number of interesting observations on the hybridisation and crossing of tropical Orchids have appeared from the pen of the Hon. F. LEDIEN, Director of the Dresden Botanical Garden. He states it is a matter of constant occurrence, and one that is of a remarkable nature, and not by any means accounted for, that certain genera and species are capable of greatly affecting, altering, or completely suppressing in their progeny the features of the species and genus with which they are crossed. A well-known example of this fact is found in *Zygopetalum Mackaii*, a species which has been frequently crossed with other species, but with the same result, the progeny being always *Z. Mackaii*, in spite of the impossibility of self-fertilisation having taken place. And similarly with the reed-like, pseudo-bulbous *Epidendrum radicans*, and likewise *E. nocturnum*, which, with the most careful crossing with other species, only result in the production of the identical species of *Epidendrum*. With *Lælia harpophylla* crossed with *Cypripedium villosum* or the reverse cross, the progeny are either *Lælia* or *Cypripedium*, according to whichever is the seed-bearing parent. Contrarywise, the prepotency of certain species by crossing is a fact that is of common knowledge, and to the raiser it is a factor of much importance. The general belief that crosses result in something midway

between the two parents holds good for species, but not for varieties when crossed. In these it is in general a fact that the darker coloured variety, say, in *Odontoglossum crispum*, is transmitted in the progeny. This is peculiarly the case when albinos (white-flowered forms) are crossed with coloured varieties in the hope of obtaining albinos, the albino never appearing in the seedlings. The raising of albinos is only successful when pollen from albinos is employed, as, for example, *Dendrobium nobile virginale*, *Cypripedium Sanderae*, and *C. x Maudiae*, but not always. In general the crossing of dark varieties upon light coloured ones should be avoided, improvements being probable only when the dark variety is fertilised with pollen from a light coloured species or variety. The crossing of distinct species both ways, always the most profitable, results in slight changes from the parents, the hybrids taken in their entirety approach the middle between the two parent forms. Exceptions to this rule are known in certain species, viz., in crosses with *Brassavola Digbyana*, with the orange-coloured *Lælia xanthina*, and *L. harpophylla*, *Cypripedium Spicerianum*, &c. The pollen influence of *Brassavola* is so great that it is potent in crosses that are otherwise unsuccessful, as, for instance, in *Cattleya citrina* crossed with *B. Digbyana*. The finest and most valuable results come from crossing species with cross breeds. The whole of the progeny of these crosses or hybrids show certainly clear traces of their origin, but likewise extraordinary differences in the gradations of development of their characteristics in form and colour. In these crosses become noticeable the peculiarities of progenitors of the bastards, which were latent in the latter, and the result is a wonderful abundance and variety of forms and colouring—a maze of variations.

RANAWARA TEA.—This preparation, sometimes called Matara tea, is made from the leaves or flowers (or a mixture of both) of *Cassia auriculata*, a common weed in dry places, known to the Cingalese as Ranawara. From a commercial point of view the plant is valuable as a source of tannin bark, but the medicinal use of the leaves dates back to a very remote period, and a decoction of them is prescribed as a blood purifier and laxative, and in the treatment of diabetes and skin diseases. Commercial samples are sometimes adulterated with caffeine.

LAW NOTES.

LILY OF THE VALLEY CROWNS.

AN action to recover the cost of a consignment of Lily of the Valley was recently heard at the Hull County Court. It was alleged by the defendant that the Dutch variety had been sent instead of the Berlin variety. The plaintiffs sued for £25 for the Lilies, and the defendant counter-claimed £20 loss and paid into court £8 8s. for *Gladiolus Blushing Bride*, which was ordered at the same time. Defendant stated that he ordered 20,000 crowns of the Berlin variety in 1905, and planted them about the middle of February. As soon as they were grown he found they were not Berlin but Dutch produce. Witnesses supported his contention that the flowers were of the Dutch variety. In the end his Honour gave a verdict for the defendant, and considered the £8 8s. paid into court a sufficient sum to pay for the *Gladiolus*. He also gave judgment for the defendant on the counter-claim for the nominal sum of 1s., plaintiffs to pay the costs. There was another similar case. The action, however, was withdrawn on payment of costs by the Dutch firm.

NURSERY NOTES.

ROYAL EXOTIC NURSERY, CHELSEA.

AT Messrs. Jas. Veitch and Sons' emporium of plants of all kinds, I found, at even this late part of the spring, a span-roofed house full of *Hippeastrums* in the best of condition as regards blossoms; and there were a few still unsold among them of pronounced large size, some with pleasing variations in the markings or colours of the blooms, not previously noted. Taken, however, as a whole, the raiser appears to be approaching the extent of possible variations with the present race. There are several species of *Amaryllids* as *Pancratium*, *Cyrtanthus*, *Eucharis*, *Doryanthes*, *Crinum*, *Nerine*, &c., which, if used as one or other parent, might afford remarkable results. It may be of interest to give a few names of the finer varieties of which flowers were in a good condition on May 3rd. *Icarus*, a large, regular-shaped flower, having a white ground without any green in the tube, and with scarlet mottling; *Tendresse*, flower scarlet, and having a white stripe on each segment and a white base to the tube. There is a purplish tinge on the scarlet parts of the flower. *Epicasta* is a fine, large scarlet self, and *Galicia* is of equally perfect form, and the same tint. *Diane* is a new break as regards colouring; *Vedas* is a large white-ground flower, flamed crimson, and with white edges to the segments; *Norma* is a scarlet-coloured variety of fine form; *Acme*, of a purplish-crimson tint, has white stripes on the segments, and is in tint rather novel and pleasing. *Ovidius* and *Pyrria* are fine selfs of different shades of crimson. The collection, with cool weather and not much sunshine, will remain for several weeks longer in flower in good condition.

The span-roofed show house contained a quantity of pretty flowering plants. There were remarked young *Ericas*, full of flower, of the varieties and species *ventricosa*, *Coccinea minor*, *hybrida*, with drooping tubular blooms, translucent, *Cavendishii*, the finest of the yellow-flowered species; *candidissima*, *perspicua erecta*, having delicate-looking pink and white flowers; *Wilmoreana*, *persoluta alba*, *fastigiata rubro-albo tincta*, &c. Of *Azalea indica* there were seen many well-known favourite varieties, and others less known as *A. carminata splendens*, *Julius Roehrs*, a crimson semi-double; *Van der Cruysen*, similar to the last-named as regards form but "old rose" in colour; *Bernard Andreas*, a semi-double white flower; and another of the same name, of a bright rose-pink tint. Several bushes of the very distinct miniature *Rhododendron racemosum* of a very dense habit of growth and very free in flowering were observed. The house is also gay with a number of plants of *Canna indica*, in self-coloured and spotted varieties; *Cytisus elegans* and *C. racemosus*, the former the more distinct in form of spike and tinge of colour, and also in lateness of flowering; *Kalanchoe Ena* and *K. Felthamensis*, the latter with larger corymbs and brighter scarlet colour. Many plants of *Boronia elatior*, full of flower, were also noted: *Streptosolen Jamesoni*, well-flowered examples of *Hydrangea Hortensia*, *Rambler Roses*, including the *Farquhar*, *Dorothy Perkins*, and others were in abundant bloom; also some well-bloomed plants of *Pyrus Scheideckeri* and *Saxifraga pyramidalis*, whose spikes of white flowers were finely developed on quite small plants in 5-inch pots. In some other houses there were observed capital examples of the finest coloured *Caladiums*, Veitch's special strain of *Schizanthus grandiflorus*, in much variety of colouring, full of bloom, and only 1½ feet in height, bushy and compact in habit, so different to *S. retusus*. A fine lot of the new Chinese *Primula Cockburniana* was seen in the house; and some plants also of *Lobelia tenuior*, so much like the old *L. gracilis*, but much less "weedy" in character. F. M.

TULIPS AT COLCHESTER.

COLCHESTER must be regarded as a town of considerable horticultural importance, for, in addition to its celebrated Rosaries, it also contains the important hardy plant nursery of Messrs. R. Wallace & Co. These nursery gardens are situated on both sides of the railway and but a short distance from Colchester station on the Great Eastern Railway. An excellent service of trains from Liverpool Street perform the journey without stopping in about one hour. The gardens extend from the north side of the railway to the banks of the river Colne, in a meadow near which has been formed a water garden, and this is planted with rare aquatic and bog-loving plants, the collection being especially rich in *Nymphæas*. The name, Kilnfield Gardens, is suggestive of brick-making, an industry which is still carried on in a corner of the grounds, and through which we wandered before finding the path leading to the nursery proper. The gardens, however, are not wholly situated upon the clay, for the soil varies in parts, and plants of different requirements in the matter of soil can be cultivated successfully; but, generally, it overlies a fine, mild brick-earth, with a subsoil. Lilies are accommodated in an old orchard, and it is found that the protection of the trees is very helpful to these bulbous plants. In all, the gardens embrace an area of about ten acres; they were established by the late Dr. Wallace many years ago, especially for the cultivation of *Liliums*, and he gathered together all the known species. Since then many rare bulbous and other plants have been introduced to commerce from this nursery, including *Hemerocallis aurantiaca major*, *Lilium Henryi*, *L. rubellum*, &c. The specialities of the firm are *Liliums*, *Irises*, *Calochorti*, and Californian bulbs in general, but about seven years ago the culture of May-flowering Tulips was taken in hand.

The collection of Tulips occupies an area of about two acres, and comprises in all about 50,000 bulbs. The varieties are not exceeding numerous, for only the very choicest kinds are grown, and any which are not up to the best standard are eliminated. Thus a batch of one very pretty flower was marked for destruction on account of its brittle stalk, the wind and rain being sufficient to break it; and another, not quite up to the best form in other respects, was similarly threatened. The first variety of which we have note is *Claude Gillot*, and this we may liken to a beautiful scarlet Oriental Poppy in colour. The flower is of large size and of admirable form. *King Harold* is not only one of the finest of the newer Tulips, but of all the race. It is a very vigorous grower, and the bloom is exceedingly large, the colour being a rich shade of crimson. *La Candeur* is white, or of a cream shade, but has a very faint suffusion of rose on the exterior of the petals. The petals of *La Tulipe Noire*, when seen in the sunlight, glow with a beautiful satiny sheen. *Flame* is a shapely flower, with much substance. The colour is a rich scarlet. *Gesneriana lutea* is of a most beautiful shade of yellow, and has the long pointed segments of the *Gesneriana* race. It is very difficult to know which to admire most, this variety or the exquisite *Golden Spire* (syn. *elegans lutea maxima*), with flowers shaded a rich buttery-yellow. A very refined variety is *Erguste*, of the Darwin type, with flowers coloured heliotrope. Europe is one of the earliest of the Darwins, and its scarlet flowers are very effective when massed in beds; it is an excellent bedding Tulip.

Fanny is of the type known as "fancy." The colour is pink, feathered with white. One of the grandest flowers of all is *Farncombe Sanders*, a bold, upstanding Tulip—a solid shade of red, with white at the base of the

petals. This is a splendid grower, and admirable for bedding purposes. Another bold flower is Antony Roozen, a shade of deep rose and a degree darker than Fanny. It is best when grown in half shade. Henner is rich red, almost maroon in colour, and has very vigorous growing foliage. Walter T. Ware, of the May-flowering type, is a pleasing shade of apricot-yellow, almost an orange. Inglescombe Yellow belongs to a set of which the others are Inglescombe Scarlet and Inglescombe Pink, three of the very best border Tulips in their respective colours. Isis is a notable variety in the scarlet-coloured section; internally the base is blue.

paler margin. The flowers are developed on tall peduncles. Landelle is a little deeper shade of red than Mme. Krelage, and has a pretty suffusion of pink at the base of the petals. It is a good grower. Doris is a dwarf, May-flowering Tulip of very prolific flowering, half a dozen flowers being common from one bulb. The colour is pink or lilac rose, margined with white and flushed with grey. Eurasian is of the same type, and has similar colouring to the last named; the flower is flushed with silvery-lilac, and is long and pointed. Glaucopsis has, like its namesake, a beautiful blue "eye," which is found at the base of the flower. The general

gus beds], Eremurus, Scillas, and many other bulbous subjects. In a wind-screened portion of the nursery, where the Myrobalan Plum forms thick hedges furnished with dense growths to the ground line, are accommodated many rare and choice rock-garden plants, and frames and "Alpine" houses are filled with interesting hardy plants. We noticed a very large stock of Saxifraga Burseriana major, and another of Habranthus pratensis (syn. fulgens). This last-named plant has rich scarlet flowers produced in pairs, the base of the petals having a yellow marking. It is a good subject for planting at the foot of a warm wall.

FIG. 141.—*PLAGIANTHUS LYALLII*, HARDY SHRUB, FLOWERS WHITE.
(See p. 332 and Supplementary Illustration.)

Good form is not its least pleasing attribute. Clara Butt is a great favourite with Tulip lovers, and it is in great demand as a market variety, being free in flowering, robust in habit, and a pretty shade of salmon-pink. Negro is dark, as its name suggests: it is a little coarser than La Tulipe Noire. Mrs. Cleveland is of the "fancy" type, white suffused with pink. Phyllis is somewhat similar to the last named, but is flushed with lilac instead of pink, and it is rather smaller in the bloom. Millet is a bold, handsome flower of a shade of maroon. It has thick, leathery segments that resist the weather well. It is a very popular variety, and being in demand is proportionately dear to purchase. The flowers are amongst the first to develop, and the last to finish. Maiden's Blush is pink, but a better flower of the same colour is Mme. Krelage. The soft pink of the petals fades to a

colouring is rose. John Ruskin is really a refined Eurasian; the mingling of gold and other colours is very pleasing. Orange King is a good, stout flower that is "alive" with colouring. It is one of the newer varieties. Royal White is interesting from the abnormal size of its stigma, which detracts from what is otherwise a beautiful flower. Hammer Hales is the latest of Messrs. Wallace's raising. It is a very large flower of orange shading, with especially beautiful coloured margins.

The above named represent the "pick" of the varieties of Tulips grown at Kilnfield Gardens. All were in remarkable vigour, and many of the choicer sorts were seen in large batches.

We have referred to the water garden; there are also whole fields planted with Lilies and large breadths of Irises [those of the Onco Reglia type being grown on ridges like Aspara-

THE CULTIVATION OF RHODODENDRONS.

In the beauty of their flowers and their extreme floriferousness there is no genus of flowering shrubs to be compared to the Rhododendron. In places which are suited to their requirements the plants flourish with freedom, and gardens not naturally suited to them in the matter of soil can be made so. During the present season their floriferousness is very marked. This, no doubt, may be accounted for by the abnormal rainfall during their growing period, last year, combined with an unusual amount of sunshine last autumn, when their wood became thoroughly ripened. It is just a century since the introduction of some of the older garden species, including *R. catawbiense*, *R. arboreum*, and *R. caucasicum*, and these have become cultivated to such an extent that, with *R. ponticum*, they are to be

found in almost every garden. It was within a year or two of 1850 that the more important Sikkim Rhododendrons were introduced by Sir Joseph Hooker, and from these have been raised a large number of hybrids with flowers of almost every shade of colour. Some of the species are mere trailing plants, but some, such as *R. ponticum* and *R. arboreum*, attain to a height of from 25 feet to 30 feet. There is also a great divergence in the foliage of the species: *R. glaucum* has leaves 1 inch to 1½ inches in length, whilst those of *R. Falconeri* are from 15 inches to 18 inches in length. The corymbs are equally as varied in size as the leaves; those of *R. Griffithianum* measure 12 inches across, with individual flowers 4 inches in width, while the whole flower truss of *R. glaucum* scarcely reaches 3 inches in its widest part.

In Cornwall a great number of species, which in other parts of the country are only half hardy, are grown in the open, and sheltered only from exceptional frosts and from strong winds, which is especially needful when cutting winds prevail during the time the plants are making their growths. There are several of these more tender species which commence to grow in February and March, and these have to be carefully watched, even in the south-west. Speaking generally, however, most of the species flourish there in the open. Violent gales are exceedingly harmful to all the Sikkim varieties of Rhododendrons, and in the case of *R. Falconeri*, with fleshy, heavy leaves, this is readily explained. These leaves, in pairs, are often 2 feet 6 inches in length, and at their greatest breadth they will measure 5 inches, thus exposing a great surface to the wind, and it is no unusual experience to find leaves of this kind wrenched off by gales. Further, if the plants are greatly exposed, the edges of the leaves turn brown, and present an appearance not unlike those often seen in injured leaves of *Bambusa palmata*, or they will lose many of their lower leaves prematurely and become "leggy." Rhododendrons dislike any appreciable quantity of lime in the soil, but they revel in fibrous peat from the granite hills. In gardens where a formation of peat upon slightly-decayed granite, or where the rock is crumbling into rubble and gravel exists, then the peat is likely to contain some of these disintegrated particles, and this mixture of gravel, Fern roots, and decomposed vegetable matter makes an admirable rooting medium for these plants. Half-decayed leaves are a good alternative to peat, but their nourishment is the sooner exhausted. Although Rhododendrons succeed best in a soil containing much humus, a soil consisting of a mass of leaves, small branches, and bits of bark mixed together, and, necessarily, in different stages of decomposition, is not an ideal rooting medium for them, and when leaves are used the only addition should be that which will assist aeration. The roots of Rhododendrons are very small and numerous, consequently, they are capable of making ready use of food at their command. Rhododendrons like a firm rooting medium, and here, again, leaves fall below peat in value, for it is almost an impossibility to press the former to anything like the solidity of the latter.

The position of a Rhododendron garden is not always a matter of choice, but a matter of necessity. Still, much may be done towards providing shelter and water, and, at the same time, towards having the plants in such a position as to be easily accessible. In the planning of a Rhododendron garden it is well to remember that isolated specimens in the open will require much more consideration in the matter of situation than plants which are placed in naturally sheltered positions. In the former case provision must be made against winds from all quarters, and in this respect advantage should be taken of any existing wind-breaks. No better site can be imagined for a Rhododendron garden than a narrow, well-wooded valley, especially when the slope is from east to west. The north side of

such a valley provides a position in which Rhododendrons are quite at home. Where no such sheltered conditions exist, resort must be made to the old-time system of sheltering the more tender species by planting the commoner varieties around them. In this respect Rhododendron *ponticum* makes a suitable screen, and in thick plantations of this species a hollow formed by removing some of the plants forms an admirable nook for the reception of more valuable species. A thick awning must be provided to protect plants which make their new growths early in the spring from frost. It should be held firmly in position, and never be allowed to beat against the young growths. A covering of dry leaves forms a good protection for the roots in winter, and a layer of half-rotten leaves prevents undue evaporation from the soil in summer.

Rhododendrons require careful planting, for if their roots are not inserted at a sufficient depth they suffer from drought, and if they are planted too deeply they suffer from lack of air at their roots. The "collar" of the plant may safely be put 2 inches above the surrounding soil, and if it is necessary to form a "cup" around the plant, it is wise even then for the plant to be slightly raised. Rhododendrons are not deep-rooting subjects, and if the subsoil is very open and porous they are liable to suffer from drought, and, on the contrary, if the subsoil is wet, there is a danger—in the absence of proper drainage—of their becoming waterlogged. The plants should never be allowed to suffer from lack of water at their roots, for if the "ball" becomes dry it is not an easy matter to thoroughly wet it again, unless water is constantly applied, and heavy applications of water should be avoided.

Seedlings are much to be preferred to grafted plants or layers, and although they require a little more time to attain a given size than plants raised from layers or grafts, they soon develop into well-balanced specimens, and there is no danger of the stock breaking into growth, as in grafted plants. Layers usually fail to make symmetrical specimens. To perpetuate a variety it becomes necessary to resort to propagation by layering or grafting. In raising plants from seeds the latter should be scattered evenly on soil that has been finely sifted and thoroughly wetted, and be just covered with sharp silver-sand. Plunge the seed pans in ashes in a cold frame, and shade them with some heavy material until the young plants appear. Gradually inure the seedlings to the influences of light and air, and as soon as they are large enough, transplant them an inch apart, in soil which contains a good sprinkling of granite grit. They should be kept in a close atmosphere and shaded for a day or two after transplanting, after which they should again be allowed freer conditions. Never allow the foliage of seedling Rhododendrons to become wet during a rapidly-falling temperature, or they will probably damp off. Sufficient drainage to the soil is imperative for the well-being of young Rhododendrons. They do not tolerate coddling, but they require good drainage, a firm yet sandy soil, and plenty of ventilation. When the plants are ready for planting in the open, choose a well-sheltered and easily-accessible quarter for them. Give them plenty of sound peat for a rooting medium, and see that they are planted firmly. It is doubtful if Rhododendrons are much benefited by the application of ammoniacal manures. If they are given any stimulant it should be in very small quantities: a sprinkling of stale soot and a top-dressing of half-rotten leaves seems to benefit them more than a heavy mulching of farmyard manure.

Nothing is gained in the matter of increasing their root growth by annually lifting the plants as is the case with many other shrubs. Any pruning should be performed in the month of May, and they will afterwards break readily into new growth and form thick bushes. The removal of any fruits that appear is distinctly favourable to the plants. *H. W., Trevice.*

PERENNIAL PLANTS FOR SUB-TROPICAL GARDENING.

THE resources for supplying an adequate number of tender plants, in variety, for furnishing a sub-tropical garden in a public park are generally considerably inadequate, but by including hardy perennials suitable for the purpose, the use of an excessive number of tender subjects is obviated and the effect produced is equally as good. The following is a selection of hardy perennials that are suitable for planting in a sub-tropical garden.

Acanthus mollis and *A. spinosissimus* are both useful. The flower spikes are displayed well above the foliage, which is both ornamental and bold in character. The species are adapted for planting in borders or in the grass, and should be given a deep soil and a sunny position.

Arundo donax and *A. conspicua* are very ornamental grasses, suitable for planting in moist situations. The culms grow to a height of 9 feet, and when surmounted by the silky-white plume of flowers they are extremely beautiful objects, especially when they are planted in masses. They luxuriate in a sandy loam.

The large-growing varieties of *Asparagus officinalis* are most graceful and elegant in appearance, and they are unrivalled for furnishing a light "foliage" effect. The roots should be planted in spring in a free, rich soil in a warm situation. The stronger growths only should be retained, and these should be staked so that the lateral growths may be extended. They are adapted for planting in the beds and borders, and attain to a height of 5 feet.

Bocconia cordata has a noble habit, and highly ornamental foliage of a greyish hue that renders it suitable for planting in the borders, or in any prominent position in the grass. It luxuriates in a rich, deep loam. The suckers must be removed as they develop, so that the crown growths may receive all the nourishment. Their height is 7 feet. *Bupthalmum speciosum* is an excellent plant for the borders; it has large, handsome leaves, and showy yellow flowers. It thrives in a rich, loamy soil; height, 3 feet.

Canna indica is one of the best plants for either the beds or borders. Although it is not generally considered a hardy plant, the roots may be left in the ground during winter provided some protection is afforded them, such as a layer of dry leaves 6 inches deep placed over the roots on the advent of frost. A light layer of soil should be thrown over the leaves to keep them in position. Protective material should be removed early in April, after which the surface soil should be lightly forked and dressed with well-decayed manure, which must be light and short. A rich, sandy loam suits Cannas, which, if given a warm situation and plenty of water will attain to a height of 6 feet. *Cynara Cardunculus* and *C. Scolymus* are ornamental foliage plants, and they prefer a rich, deep soil. Not more than three growths should be allowed to develop on each plant. The roots must be protected with a little litter or ashes during the winter months; height, 5 feet. *Echinops exaltatus* is an excellent subject for planting in the borders, and is serviceable both for foliage and flower effect. It grows well in ordinary soil, but being a gross feeder it responds quickly to liberal applications of manure water or mulchings around the roots, and attains to a height of 7 feet or more. *Eremurus robustus*, *E. Himalicus*, *E. Bungei*, and their varieties are unrivalled for producing a stately floral display. A deep, sandy loam suits their requirements. The young leaves should be protected in early spring by small branches of any suitable evergreen stuck in the ground around them. The habit and finely divided foliage of *Ferula communis* and *F. tingitana* render them useful subjects for planting in the borders. They are impatient of disturbance at their roots, and on this account it is necessary to plant young

seedlings in the permanent quarters. *Funkia Sieboldiana*, *F. ovata*, and *F. sub-cordata* are all well suited for planting in the front of borders and beds. The white flowers of the last-named species are very fine, but unfortunately they soon fade and drop; the foliage, however, is highly ornamental, being of a pale green tint. The variegated variety of *Funkia ovata* is also good. All the *Funkias* revel in a rich loam. *Gunnera manicata* and *G. scabra*, without which no sub-tropical garden is complete, are best planted in single crowns in prominent situations in the grass. They luxuriate in a rich, deep soil in moist situations that are partly shaded; they attain to a height of 9 feet. *Gynerium argenteum* and its varieties are all excellent plants, either for the borders or for planting in the grass. They like a free, rich soil, and should be watered frequently during the early stages of their growth. *Helianthus tuberosus* gives a good effect when planted in

grass. *P. sachalinense* is a first-rate subject to plant in moist situations for foliage effect only, and if mulched with well-decayed manure in early spring it will very quickly develop shoots, attaining a height of 12 feet. *Pulmonaria saccharata* and *P. officinalis* have both mottled foliage. *Rheum nobile* and *R. officinalis* are excellent foliage plants, and have leaves somewhat like those of a *Gunnera*. *Saxifraga purpurascens* may be utilised for the margin of beds and borders. It grows very freely and has a height of 9 inches. *Spiraea aruncus* and varieties, *S. lobata*, and *S. gigantea* are all suited for planting in moist and shady situations. Their leaves are all more or less pinnate, and the terminal spikes or panicles of flowers are very beautiful. *S. aruncus* grows 3 feet, and *S. lobata* and *S. gigantea* 6 to 8 feet in height. *Stachys lanata* and *Veratrum album* and *V. nigrum* are also suited for this style of gardening. *Puisse.*

Dendrobium speciosum Bancroftianum, imperfectly described by the late Professor Reichenbach in *The Gardeners' Chronicle*, 1881, p. 782, is more probably *D. fusiforme*, unless the type plant differs from those which have appeared in gardens.

Dendrobium Falcorostrum figured in Fitzgerald's *Australian Orchids*, 1879, vol. i., part v., t. 4, is also an allied species, intermediate in growth between *D. fusiforme* and *D. speciosum Hillii*. *Dendrobium speciosum* and its varieties and allies are very easy of culture if treated as warm greenhouse or conservatory plants, and exposed for a considerable time in the open air during the heat of the summer, or placed in a sunny position in an airy vinery or fruit-house. The ordinary Orchid-house is usually too moist for the Australian Orchids, except in their growing season, and if they are not given more airy quarters during the summer months they fail to flower, and usually decline in health. *J. O'B.*

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

STRAWBERRY ROYAL SOVEREIGN.—I note with pleasure the manner in which *A. D.* extols this Strawberry (p. 321) for its excellent cropping and other qualities, but his statement that large fruits represent very grossly-grown and severely-thinned crops is an erroneous one. I have had under my observation during the present season a large batch of Strawberries of the above-mentioned variety, from which were picked fruits of the finest flavour, and a large proportion of them weighed fully two ounces each, from plants carrying in nearly every instance eight fruits. This, I think, can scarcely be considered severe thinning. With reference to his remark as to large fruits being grossly grown, I may say the fruits I mention were fed with an artificial manure, diluted in water at the rate of a teaspoonful to a gallon, and applied to the plants at every third watering. I think this cannot justly be termed gross feeding, especially when one takes into consideration the small space in which they are grown in pots. *D. W.*

I have no doubt whatever that this variety "has come to stay," till something better takes the fancy of gardeners and market-cultivators. Any gardener with experience of Strawberries, if he can free himself from the glamour of size and colour and firmness of pulp in Royal Sovereign, could name half-a-dozen varieties of undoubted excellence, which would prove pleasant eating, bear travel as well, and be more free from acidity, as free in cropping, as good and strong in growth, and as suitable for forcing as the variety in question. The fruits shown at the Royal Horticultural Society's meeting were the produce of grossly-fed plants grown in pots. But how many plants were looked over in order to obtain the number of monster berries the exhibitor put up we do not know, and the exhibitor did not proffer the information. I am still of the opinion that there are better "eating" Strawberries than Royal Sovereign. *F. M.*

SUMMER BEDDING IN PUBLIC PARKS.—Mr. Pettigrew's article on this subject (p. 315) is most interesting. The difficulty which responsible superintendents are likely to experience if attempts be made in public parks to introduce any original ideas or different styles of bedding, other than those the public are accustomed to, is unfortunately great, but in a few instances the public taste for a more natural style of bedding is evidenced. In some of the London parks, where other effects in bedding have been introduced, I frequently hear remarks passed commending the advance that has been made, and such remarks have emanated from all classes. This seems to show that the system of bedding, in which carpet and other formal designs predominate, should be largely curtailed, and should be superseded by a freer or mixed style. No gardener would advocate the abolition of Pelargoniums for bedding purposes, but, in my opinion, they seem to be used more frequently than is necessary. Want of variety leads to satiety, therefore departure from the present, largely-adopted, formal style of bedding is desirable. *Puisse.*

FIG. 142.—DENDROBIUM FUSIFORME: FLOWERS CREAM-WHITE WITH PURPLE LINES ON THE LIP.

groups in the borders, and will attain to a height of 10 feet when planted in rich soil.

Hieracium villosus is too coarse to introduce into the beds or borders, but it is a good subject for the shrubbery. *Lilium giganteum* is admirably adapted for planting in borders that are cool and shaded. It is advisable to plant sound bulbs of less than medium size, for although larger bulbs may flower the first year after planting, smaller bulbs that can establish themselves before they reach a flowering size give more satisfactory results. They succeed in a deep, free, rich soil. *Miscanthus japonica* and its varieties *striata* and *zebrina*, are ornamental grasses that do well in a rich, loamy soil. They should be given plenty of water when growing. Another grass, *Pennisetum latifolium*, should be planted in a snug corner in the borders in a rich, sandy soil. The roots must be protected during the winter by placing a thatch of dry straw 6 inches thick over them. *Panicum virgatum* is finer than the two preceding grasses and will grow in any good soil. *Polygonum cuspidatum* is an excellent subject, on account of its foliage and flowering, for planting in the

DENDROBIUM FUSIFORME.

THE accompanying illustration (fig. 142) of this interesting and rare species is from a photograph kindly sent by Sir Chas. W. Strickland, Bart., Hildenley, Malton, Yorks., who received the plant from Queensland with other species collected by his son, Mr. W. W. Strickland. The species was described by Mr. F. M. Bailey in the *Proceedings of the Linnean Society of New South Wales*, vol. ii., p. 227, wherein it is stated to be "common on the trees of the northern coastal scrub."

The flowers are cream-white, with small purple lines on the lip, and the form, as seen in this species, is common to many of the Australian *Dendrobiums*, although they differ much in their habit of growth, which probably accounts for the plant under notice being originally placed as a variety of *D. speciosum*, for it was considered to be a further extension of the species beyond the variety *Hillii*, which is a true *D. speciosum*.

THE BRITISH GARDENERS' ASSOCIATION.—The progress, being made by the above society is most satisfactory, and gardeners have well responded to the call. With a roll of over 1,000 members, a strong united council, and an indefatigable, experienced secretary, it should be possible to accomplish some really substantial work for the benefit of gardeners. The approaching annual meeting and the report for the past year will, therefore, be anticipated with the keenest interest. Judging only by the evidence yet before them, many earnest members are, however, becoming anxious to know how far the promises and inducements of the promoters are being realised. Questions are asked in various directions that will require very clear and comprehensive replies to give satisfaction. During a long journey in counties remote from the Metropolis, it has come to my knowledge that a feeling of uncertainty prevails, and if this be not promptly removed, the council will find themselves exposed to the danger of a seriously-diminished membership. The various subjects concerning which doubts are expressed may be condensed into the following questions: (1) What has been done in bringing employers needing gardeners into correspondence with members requiring situations? In other words, how far has the registry system answered, and how many members have secured appointments through the association? (2) Has the status of gardeners been improved in any direction, to what extent, and by what means? (3) Has the association, organised any educational help for gardeners, or what is proposed to be done in this important matter? Much dissatisfaction is expressed with the so-called "certificate" that members receive; it is surely a misuse of terms to denominate such a production a "certificate." It might have been more fittingly termed an annual ticket or receipt. It appears from the reports that it is suggested an excursion of members to Continental gardens and nurseries should be organised. Such journeys are undoubtedly beneficial, but they can only come within the means of a few gardeners. Much more serious work awaits the association than arranging for outings that can only be of advantage to a comparatively small number of members. A proposal to publish a quarterly journal has also been reported, but why "quarterly"? It was said the association was to be an up-to-date body, yet the council falls back upon the antiquated system of issuing a quarterly publication, which is mainly confined to a few learned societies. What benefit such a journal will confer upon members it is difficult to understand in these times of stress? The association is so greatly needed and should be able to render such valuable assistance to its members, that some of its most earnest supporters (including the writer) have but one desire in any criticism or enquiries, namely, to see it placed upon the broadest possible basis, and performing the greatest amount of useful work in an efficient manner. *Lewis Castle.*

TO PRUNE OR NOT TO PRUNE.—I accept Mr. Udale's prices and quantities as far as they apply. I have been experimenting with an open mind, for a very long period, and in not one single instance does my experience tally with his, whereas it does agree with the systematic Woburn experiments thoroughly, as far as crops and quality go. I never troubled much about the weight of the trees, but heavy crops of good fruits produced in the shortest time have always been my test. My proposition, which Mr. Udale disregards, is that under equal cultural conditions the non-pruned trees greatly surpassed the pruned ones in weight of crop, whilst the quality is not inferior. Unless Mr. Udale's experiments were carried out and verified under these conditions they are worth nothing. We have Mr. Udale's admission (p. 249) that as regards weight of crop his own non-pruned trees beat the pruned ones by about a hundred per cent. The quality only is in dispute. My business takes me over the length and breadth of Great Britain, and I see all kinds of orchards, and venture to say that if any garden practice is doomed it is the stupid kind of pruning that has been in vogue for so long a period. Whole plantations of formally trained fruit trees of the pyramid type are being consigned to the rubbish heap and are being replaced by more naturally trained trees and bushes that are just slightly trimmed to preserve their shape and balance. An orchard of

pyramids filling half of a walled-in kitchen garden, and that had given next to nothing but trouble and disappointment to the owner and his gardener for years, was recently dug up and replaced with young trees. There were nearly 100 established pyramids, costing about 15s. each when planted, and they have been replaced by small standard trained plants at from 1s. 6d. to 2s. each, and are now fruiting freely the second year. A plan now commonly adopted with pyramid-trained trees is to convert them into standards by sawing off their bottom branches and allowing the top to develop. A gentleman in the New Forest sends me photographs to show how successful he has been in this treatment of his severely trained trees, and another in Galloway, N.B., writes me that he fears nothing now but late frosts, and never had such large crops. I suggest that owners are not likely to thus destroy trees they have purchased at great expense without some good reason. *J. Simpson.*

THE FRUIT COMMITTEE AND ITS DUTIES.—It is not customary for individuals, or bodies of individuals, to wish for more work. The members of the Fruit Committee are exceptions to such rule. At their last meeting, having so little to do, characteristic of many meetings in the spring, it was unanimously agreed to empower the chairman, Mr. J. Bunyard, to confer with the chairman of the Floral Committee, that body having a great excess of work, with the object of coming to an arrangement whereby all entries and groups of hardy shrubs and trees sent to the society's meetings be transferred to the Fruit Committee for consideration. Of course, the final consideration of the matter will rest with the council, even should the Floral Committee agree. It does seem absurd to have a gathering of some 30 experts at the Fruit Committee's table, and practically nothing for them to do. All the same, no one can question but that these experts are as capable of adjudicating on the merits of shrubs and trees as are the members of the Floral Committee. *Member.*

SALVIA SPLENDENS COMPACTA "ZURICH."—This novelty, raised by the firm of Otto Froebel, of Zurich, is the subject of an illustration in a German gardening journal. It is described as a capital autumnal plant for cultivation in beds and pots, and will, it is thought, be very commonly grown in the future. The plant possesses extraordinary floriferousness; the growth is compact and dwarf, and the flower spikes of considerable length. Planted out in the month of May it flowers early and continuously till November. The colour of the flowers is a glowing scarlet. Some have already seen the plant in cultivation at Wisley. *M.*

PSYLLA MALI (APPLE SUCKER).—Those who are suffering from this serious and rapidly extending pest will be anxious to learn what success has attended its treatment with the Woburn wash. Various assertions, for which the Woburn authorities are in no way responsible, have been made that this wash is a certain remedy for Psylla; but the past season is the first during which the action of the wash on the Psylla eggs has been examined, and it is only now, when the hatching is complete, that it is possible to tell what the result has been. From these experiments it appears that the wash of the strength advocated for mussel scale (6 per cent. of paraffin and 2 per cent. of caustic soda, copper sulphate being used as emulsifier; see *Gardeners' Chronicle*, February 16, 1907) will be ineffective; but results have been obtained which indicate the direction in which success may probably be obtained in future. In the first place, branches infested with the eggs were treated with the wash in a manner more thorough than could be adopted in ordinary practice, for they were momentarily dipped into the liquid; but of some 400 eggs on the branches every one eventually hatched out. It was noticeable, however, that the date of hatching was considerably delayed by the treatment, thus affording evidence that the wash was not altogether without effect. It was found that an increase of the paraffin to 12 per cent., or more, caused a complete mortality of the eggs: out of 1,100 eggs on the branches thus treated, only 11 hatched out. As the wash with 12, and even 18 per cent. of paraffin was found to cause no appreciable injury to the trees, these results sound very satisfactory; but they are discounted

by the difficulty of applying wash to growing trees in the same thorough manner as it can be applied to a few branches in experiment. The case is very different from that of the mussel scale, where the eggs are deposited chiefly on the trunk and main branches. The result was that Woburn wash of from 12 to 18 per cent. strength, though fatal when applied to severed branches, caused but little mortality when applied to large trees in the open, the action not getting much beyond the stage of delaying the hatching, similar to that of the weaker emulsion (6 per cent.) on the experimented branches above noted. In the absence of a more perfect method of application (which may, perhaps, be forthcoming), it is evident that a still stronger insecticide is required in practice. Some other experiments indicate how this may be obtained without unduly increasing the percentage of paraffin. In pursuance of a suggestion which we made as to the nature of the action of insecticides on eggs (6th Woburn report, p. 130), the effect of a 10 per cent. solution of salt was tried, both alone and in conjunction with 2 per cent. of caustic soda, and the results were very promising, the mortality caused on severed branches being 83 and 93 per cent., respectively. It is probable, therefore, that the addition of this amount of salt to the Woburn wash will greatly increase its efficacy, and thanks to the possibility of substituting copper or iron sulphate as an emulsifier in the place of soap, there is no difficulty in making this addition. We must wait, however, for another season before trying the combination. It may be mentioned that the joint use of caustic soda and paraffin has been found to result in the same remarkable increase of action (as compared with that of either of the substances separately) in the case of the Psylla, as it did in that of the mussel scale; also, that lime cannot be used as an efficient substitute for soda, even when taken in five-fold proportion. The efficacy of the wash increases rapidly with the percentage of soda present, but, unfortunately, 2 per cent. is the maximum amount which can be used with safety to the trees or to the workmen who apply it. We find also that the lime-soda-sulphur-salt washes are practically useless for the destruction of Psylla, but this, as well as the statement just made as to lime being an inefficient substitute for soda, does not necessarily militate against the good results which appear to have been obtained by Mr. Chapman with a lime-salt wash (details of which are now appearing elsewhere), for the proportion of lime (20 per cent.) used by this experimenter is far in excess of that used in any of the Woburn trials. Probably, as with mussel scale, it will be advisable to supplement any winter wash which may be used by a weaker wash applied at the time when any undestroyed eggs are hatching. Experiments are being made in this direction, and, so far, excellent results have been obtained with a tobacco wash of a certain strength. *Spencer Pickering.*

SOCIETIES.

ROYAL HORTICULTURAL Scientific Committee.

MAY 14.—*Present:* Mr. G. Massee, V.M.H. (in the chair); Drs. A. B. Rendle, M. C. Cooke; Messrs. H. J. Veitch, G. S. Saunders, F. J. Baker, A. Worsley, A. W. Sutton, J. T. Bennett-Pöe, C. T. Drury, W. C. Worsdell, J. Douglas, E. A. Bowles, G. Gordon, W. Cuthbertson, and F. J. Chittenden (hon. sec.).

Contorted Carnation.—Mr. WORSDELL said he had further examined the curious Carnation plant shown by Dr. MASTERS at the last meeting, and remarked that DE VRIES had suggested that such contorted growths were the result of a reversion to a spiral arrangement of leaves, departing from the opposite decussate arrangement usual in the plant. Dissection of the bud appeared to support this view. In the specimen shown the leaves were also curiously rolled back.

Fungus on Retinospora.—Mr. MASSEE said that the fungus shown at the last meeting by Mr. SAUNDERS on Retinospora was Gymnosporangium clavariiforme.

Growth of Fern in Bottle.—Mr. DREYER showed the result of placing a small half-inch piece of the base of a frond of Scolopendrium vulgare

on a layer of well-washed silver sand, one inch deep, thoroughly moistened and located at the bottom of a pickle jar. The severed piece bore an incipient bud. The pickle jar was then tightly closed by means of a glass stopper, provided with a rubber ring. The exhibit represented the result of two years' growth without the admission of any air, the stopper having been wired on. The Fern had a number of fronds about 6 inches in height, and new ones were rising; there were also one or two seedlings, believed to be *Lastreas*. A mass of filamentous algae covered the sand and part of the bottle. The whole of this vegetative growth had been developed under the presumed air-tight conditions described. Members pointed out, however, the possibility of the diffusion of air even under the conditions described, and the fact that, as tap water had been used in washing and moistening the sand, a certain quantity of soluble earth salts had been originally admitted into the bottle.

Picea orientalis.—Mr. BOWLES showed, on behalf of Canon ELLACOMBE, inflorescences and cones of this beautiful Conifer.

Colouration of Apple flowers and fruit.—Mr. H. J. VEITCH showed a long series of flowers of Apples, some having white or only very slightly tinged flowers, while others had deeply-coloured flowers. He remarked that in each case the pale-flowered Apple trees bore very brightly-coloured fruits, while those with deeply-coloured flowers produced pale fruits. Mr. CUTHBERTSON said he had observed a similar thing in Turnips, as in the Golden Tankard, a Turnip with yellow flesh, that produced white flowers. Mr. BOWLES said that the rule was not without exception, as in *Pyrus Niedzwetzkyana*, both the flowers and the fruits are very deeply coloured.

Richardias.—CHAS. WOODBRIDGE, Esq., sent an inflorescence of *Richardia Elliottiana*, having a leaf arising close below the yellow spathe and coloured like the spathe, except that the margin and tip were green. Mr. VEITCH showed R. × Mrs. Roosevelt having a leaf arising from the base of the plant, as is usual, coloured very pale green, except at the tip, which was similar in colour to the spathe.

Double Ribes.—A branch with very much doubled flowers of *Ribes atro-sanguinea*, from Sir E. LODER (gr. Mr. W. A. Cook), of Leonardslee, was referred to Mr. WORSDELL.

Potatoes.—Mr. A. W. SUTTON showed a very extensive and exceedingly interesting series of plants of tuberous *Solanums*. Particularly interesting were those of "Papa Silvestre" (*Solanum Commersoni*), the wild Potato of Uruguay. The examples had been grown from tubers received direct from Montevideo. Five separate consignments of these tubers have reached Mr. SUTTON from his correspondent, who had himself collected the tubers in several different localities far away from any cultivated land. The separate lots of tubers were found growing under very different conditions as regards soil and locality, but in no case near cultivated land. In each instance, so far as the plants have as yet developed, there is every reason to think that each lot of tubers represents one and the same species. With the last consignment Mr. SUTTON received a certificate from Señor ARECHAVELETA, Curator of the Botanical Gardens, Montevideo, certifying that the tubers then sent were the true *Solanum Commersoni* agreeing in all respects with the plant introduced by Commerson in 1767. Señor ARECHAVELETA further stated that all the wild Potatoes found in Uruguay were one and the same type, and that they all bore violet-coloured flowers. Mr. SUTTON produced Monsieur ROZE's book entitled *Histoire de la Pomme de Terre*, in which there is an illustration and description of Commerson's original plants fully confirming Señor ARECHAVELETA's statement concerning the wild types of Potato in Uruguay. In connection with the exhibit Mr. SUTTON called attention to the fact that so far as his information went, all the plants hitherto grown in Europe under the name *Solanum Commersoni* were of the white-flowered type, and it was certainly the white-flowered type which Mons. LABERGIERE had experimented with. The white-flowered plant was apparently introduced to Europe (Marseilles) between 1895 and 1901, and has since been cultivated under the name *Solanum Commersoni*.

Mr. SUTTON also exhibited the following:—

1. "*Solanum tuberosum*, wild species," grown from tubers raised from seed received from Vermont Agricultural Experiment Station, 1906. This seed was collected in Mexico.

1a. "*Solanum tuberosum*, wild species," from seed saved from the foregoing at Reading in 1906.

1b. "*Solanum tuberosum*, wild species." Seedling plants raised from seed received from Vermont in 1907.

These three lots of seedlings so far exhibit no variations, but promise to come quite true from seed, and to be uniform in character.

1c. Seedlings raised by crossing No. 1 with pollen from white-flowering *Solanum Commersoni* at Reading in 1906.

1d. Seedlings from No. 1 crossed with pollen of *Solanum tuberosum*.

2. "*Solanum tuberosum* (new wild species)" collected in Mexico. Grown from seed saved at Vermont in 1906.

3. *Solanum Maglia*. Grown from tubers received from Mr. Baker of Kew in 1886.

4. *Solanum verrucosum*. Grown from tubers raised from seed received from Vermont Agricultural Experiment Station, 1906.

4a. *S. verrucosum* seedlings from seed saved from No. 4 at Reading in 1906.

4b. *S. verrucosum* raised from seed received direct from Vermont, 1906.

5. *S. polyanthemum* from seed received from Vermont in 1906.

5a. *S. polyanthemum* from seed saved at Reading from tubers raised from No. 5.

It is remarkable that seedlings of all the above wild types appear to come true and quite uniform, when it is remembered that in the case of no cultivated Potato do the seedlings come either uniformly true to each other or to the parent.

A hearty vote of thanks was accorded to Mr. SUTTON for his very interesting and comprehensive exhibit.

HORTICULTURAL CLUB.

LECTURE ON SMALL HOLDINGS.

MAY 14.—The usual monthly dinner of this club was held at the Hotel Windsor on the above date, Mr. Harry J. Veitch presiding, whilst among the guests were the Right Hon. Jesse Collings, M.P., Messrs. R. Winfrey, M.P., E. Hudson, William Robinson, G. Meldrum, G. Hurd, and others interested in the question of "Small Holdings." This subject was opened by Mr. P. Anderson Graham in a brief address, in which he referred to the historical aspect of the question, prior to the Act of Parliament involving the enclosure of large areas of common land. This step, though beneficial in some respects from an agricultural point of view, involved the great disadvantage of withdrawing from a very large number of men just that amount of aid in the shape of free pasture for cattle, &c., which enabled them to hold their own. The compensation given them for this only afforded temporary relief. Many attempts have been subsequently made to cure the consequent evil of depletion of the rural population, but with little success. The discussion eventually resolved itself into an exchange of decidedly conflicting views as to the reason. Mr. Graham himself appears to be inspired with anything but sanguine hopes of a restoration to previous conditions of rural farming on a small scale, the old factors having entirely disappeared in favour of new ones which are antagonistic to that quiet sort of life which formerly prevailed with rural people, many of whom were content to live and die, it might be, in the parish they were born in, the holdings passing on from generation to generation. The quality of the land was also a material factor in the problem, and in the cases cited where success had attended the acquisition of land and its distribution among small holders, they were mostly sufficiently near to towns to admit of intensive culture of market produce at a profit.

Mr. Winfrey, M.P., followed Mr. Graham, and, as one connected with the present Government, gave some particulars of what had been done by letting acquired areas on terms which assisted those to commence as small farmers who wished to do so. All these arrangements, however, appeared to be made on the basis of rental, and not of out and out acquisition; and Mr. Jesse Collings, following Mr. Winfrey,

advocated in the most eloquent manner the need of absolute ownership as an incentive to that thoroughgoing industry and thrift which is essential to success. No man, he contended, will devote the proper amount of labour to a holding which is in any way subject to another man's control as regards possession, knowing that sooner or later he may see the fruits of his energy and the improvements in the holding resulting therefrom go to benefit another. All tenancy arrangements made so far, he maintained, were subject to this drawback. The only proper way was to provide the willing man, having but little capital, with the purchase money, which should be secured on the land itself and be repayable on easy terms. Given such conditions, Mr. Collings maintained that the present evil would right itself, and the rural district would become repopulated with a contented and thriving community of farmers and small holders.

The eloquence with which Mr. Collings discussed this subject with which his name has been so long associated was most impressive, but not a few of his hearers differed widely from him in his conception of the percentage of men who would rise to his ideal and profit, as he assumed, to the utmost by the facilities afforded. The failures he estimated at but a small percentage, and he laid but little stress upon the evils and troubles attendant upon permanent ownership granted to undeserving or incapable persons. Mr. Graham, in his subsequent reply, differed entirely from the optimistic views which had been expressed. The discussion, in fact, terminated in two diametrically opposed views, without a definite summing up, and the Rev. G. H. Engleheart expressed the wish of all that the subject might be further ventilated on a future occasion.

ROYAL NATIONAL TULIP.

MAY 22.—The fourteenth annual exhibition of this society was held in the gardens of the Royal Botanic Society, Regent's Park. The competitive exhibits were not numerous, but the number of entries showed a slight increase on those of last year. A good attendance of visitors was seen in the exhibition during the afternoon. Non-competitive exhibits were very finely staged by trade-growers.

COMPETITIVE CLASSES.

In the important class for 12 dissimilar rectified Tulips, there were five entries, and the first prize was won by Mr. W. WHITTAKER, Hull, Cheshire; 2nd, Mr. A. D. HALL, Harpenden.

In the smaller class for six similar blooms as in the foregoing, Mr. J. W. BENTLEY, Castleton, Lancashire, won the 1st prize, and Mr. HALL was again awarded the 2nd prize.

The best three blooms of feathered Tulips were shown by Mr. HY. WILLAKER, Harpenden, and Mr. HALL was again second, but Mr. HALL was first in the class for three flamed varieties, Mr. WHITTAKER gaining the 2nd prize.

In the class for six dissimilar breeder Tulips, Miss WILLMOTT secured the 1st prize, and Mr. WHITTAKER the 2nd.

Mr. WHITTAKER was first for three varieties, thus changing positions with Miss WILLMOTT, who was awarded the 2nd prize.

Only one entry was seen in the class for six Darwin varieties, Mr. LOVAT, Oxford, exhibiting very fine blooms of Loveliness, Grand Monarque, Fontanella, Europe, Gretchen, and Flambeau, all really good varieties.

In the class for 12 varieties of garden Tulips there was again only one entry, but the exhibit which was from Mr. W. C. BULL, Ramsgate, was very good.

The exhibit of 12 varieties of Darwin Tulips from the same exhibitor was excellent, but there was no competition, and this gentleman was again the only one exhibitor in a class for one variety arranged for effect. Mr. BULL was awarded the 1st prize.

TRADE EXHIBITS.

Messrs. HOGG & ROBERTSON, Dublin, made a grand exhibit of Tulips, and very fine blooms of the St. Brigid Anemones. (Large Silver-Gilt Medal.)

A Certificate of Merit was given Messrs. HOGG & ROBERTSON for Scotia, a fine scarlet Tulip with yellow markings.

Messrs. R. WALLACE & Co., Colchester, made a fine exhibit of Darwin and late-flowering varieties of Tulips. (Large Silver-Gilt Medal.)

Messrs. BARR & SONS, Covent Garden, made a very extensive exhibit of these flowers, of which striped varieties were a great feature. (Gold Medal.)

Messrs. W. PAUL & SON, Waltham Cross, put up a nice group of Roses, amongst which *Hiawatha* was in splendid condition. (Silver-Gilt Medal.)

Messrs. H. Low & Co., Enfield, exhibited a group of greenhouse flowering plants. (Large Silver Medal.)

Messrs. J. PEED & SON, Norwood, had an exhibit of Gloxinias, also a group of Japanese Maples, and another of rock plants. The Gloxinias were exceptionally fine. (Gold Medal.)

ROYAL METEOROLOGICAL.

MAY 15.—The first of the afternoon meetings for the present session was held on the above date at the society's rooms, 70, Victoria Street, Westminster, Dr. H. R. Mill (president) in the chair.

Dr. Mill read a paper on "The Standard Rain Gauge, with notes on other Forms." When the late Mr. Symons founded the British Rain-fall Organisation 47 years ago, such observations as were then being carried on were made with rain gauges of the most varied patterns, set up at any height from the ground that suggested itself to the observer, and read irregularly at almost any hour of the day or night. Since that time there has been a steady approximation to uniformity, and now the greater number of rain gauges in use are of a few definite patterns, set for the most part at nearly the same height above the ground. Dr. Mill strongly recommends the Snowdon pattern rain gauge, which is 5 inches in diameter, has a vertical rim to the funnel of 4 inches, and has an inner can and also a bottle. He does not recommend rain gauges with shallow funnels, nor the Howard and Glaisher patterns.

Obituary.

GEORGE ROEMER.—There died on May 17 last the well-known florist and nurseryman, George Roemer, of Quedlinburg, in the 41st year of his age. The firm of which he was a member is celebrated for its superior strains of Cinerarias, Primulas, winter-flowering and other Stocks, Asters, and flower seeds in general.

ENQUIRIES AND REPLIES.

CAN any reader inform W. M. how to prevent maggots from entering drawers used for the storing of seeds?

ANSWERS TO CORRESPONDENTS.

* * The Editor will be glad to receive, for consideration, large photographs of horticultural subjects, suitable for forming Supplementary Illustrations to this Journal.

AGREEMENT RESPECTING REPAIRS TO NURSERY BUILDINGS: W. D. T. You had better consult a local surveyor, who will inspect the buildings, and see if their condition is in accordance with the terms in the agreement.

ASTERS AND STOCKS: F. E. S. There may be wireworms in the soil, but whether this is the case, or the failure is due to fungus disease, it is impossible for us to say, unless we receive specimens for examination.

BRACKEN FERN: H. C. T. *Pteris aquilina* is difficult to raise from spores. The soil in the spore-pans should be sterilised, and the pans stood about one quarter their depth in other receptacles of water. This will provide sufficient moisture, and prevent the spores being washed away by the watering can. The best plan of establishing this plant is to remove whole sods with the rhizomes and to plant these boldly in their new quarters.

CELOSIA PLANTS UNHEALTHY: E. G. No disease caused by insects or by fungi is present on the plants. The unhealthy appearance suggests injury from fumes arising from the heating apparatus.

CUPRESSUS LAWSONIANA VAR.: A. H. We can find no trace of injury by insects on the shoot submitted, and the plant is apparently either constitutionally wrong, or there may be something injuring its roots.

HYBRIDISATION CONFERENCE: C. A. McC. The report of this meeting, and also all other publications of the Royal Horticultural Society, can be obtained from the secretary, Rev. W. Wilks, Royal Horticultural Hall, Vincent Square, Westminster, London.

INSECTS ON HORSE CHESTNUT: Waldegrave. The specimens you send are common weevils. See answer to H. P. in last week's issue.

MARKET-GARDENING: Sussex Amateur. We should advise you to make sowings of the following varieties of Peas at once: Chelsea Gem, Daisy, and Omega; the last-named Pea is a variety of the Ne Plus Ultra type, growing 2½ feet high. Chelsea Gem and Daisy attain to an average height of 1 foot and 2 feet respectively, and, therefore, may be sown in rows at from 18 inches to 24 inches apart. Autocrat is another good late Pea of the Omega type, but grows 6 inches higher; it is a prodigious cropper, producing large, handsome, well-filled pods of fine quality Peas. Potatoes Goldfinder and Up-to-Date will suit your purpose in every way, being good growers and heavy croppers. The tubers are of large size, good shape, and firm in quality; if properly cooked, they become like balls of flour. You should make liberal plantings, as soon as possible, of Early London, Walcheren, and Autumn Giant Cauliflowers, afterwards planting Broccoli of the following varieties, which will yield an almost unbroken succession of "heads" from the end of July next until June, 1908, viz.: Self-protecting, Michaelmas White, Autumn White, Winter White, Frogmore Protecting, Champion, Eclipse, Wilcove White, Mammoth Spring White, Model, Evesham Giant White (of Self-protecting habit turning in May), Mont Blanc, and Late Queen. *Kales:* Cottager's and Scotch (green curled), also Colewort Rosette and Hardy Green. *Cabbages:* Ellam's Dwarf Early Spring and Enfield Market will answer your purpose. *Savoy:* Early Covent Garden strain, Drumhead, Green Curled, and Dwarf Elm are good varieties of this hardy green vegetable to rely upon for yielding satisfactory supplies of good, solid "heads," no matter how severe the winter may be. *Beet:* Covent Garden Red and Pine Apple are suitable varieties to grow, and the seed should be sown at once. A month or six weeks earlier would have been better.

MUSCAT GRAPES: Muscat. The unhealthy appearance of the leaves is due to some defect in cultivation, and not to excess of air. Better drainage of the border would probably prove beneficial.

NAMES OF FLOWERS, FRUITS AND PLANTS.—We are anxious to oblige correspondents as far as we consistently can, but they must bear in mind that it is no part of our duty to our subscribers to name either flowers or fruits. Such work entails considerable outlay, both of time and money, and cannot be allowed to disorganise the preparations for the weekly issue, or to encroach upon time required for the conduct of the paper. Correspondents should never send more than six plants or fruits at one time: they should be very careful to pack and label them properly, to give every information as to the county the fruits are grown in, and to send ripe, or nearly ripe, specimens which show the character of the variety. By neglecting these precautions correspondents add greatly to our labour, and run the risk of delay and incorrect determinations. *Correspondents not answered in one issue are requested to be so good as to consult the following numbers.* **PLANTS:** F. G. B. 1, *Veronica gentianoides* alba; 2, *Ajuga reptans*; 3, *Alyssum saxatile*; 4, *Arenaria grandiflora*; 5, *Spiræa Thunbergii*; 6, *Euxochorda grandiflora*.—H. E. A. *Orobanche coerulescens*, a parasitic plant introduced in the potting soil.—F. R. 1, *Scilla campanulata* varieties; 2, *Ruscus aculeatus* (Butcher's Broom); 3, *Cercis siliquastrum* (Judas Tree); 4, *Pæonia tenuifolia*; 5, *Anemone alba*; 6, *Genista hispanica*; 7, *Cardamine pratensis flore plena*; 8, *Euonymus latifolius variegatus*.—

D. R. *Salvia leucantha*.—G. H. 1, *Coleonema* (*Diosma*) album; 2, not recognised.—W. R. 1, *Muscari comosum*; 2, *Dipcadi serotinum*.—K. and B. *Abies magnifica*.—J. S. 1, *Ruscus Hypoglossum*; 2, *Leucothoe Catesbaei*; 3, *Pinus excelsa*; 4, P. Laricio; 5, *Cryptomeria japonica*; 6, *Pseudotsuga Douglasii*.—W. G. S. 1, *Odontoglossum gloriosum*; 2, O. Andersonianum, a very good variety.—T. T. 1, *Bletia hyacinthina*; 2, *Eria convallarioides*; 3, *Sarcanthus teretifolius*; 4, *Luisia volucris*; 5, *Macradenia lutescens*; 6, *Gongora cassidea*.—Constant Reader. Yellow Banksian Rose.—A. M. 1, *Ruellia Portellæ*; 2, next week; 3, *Ribes alpinum*; 4, *Ribes aureum*; 5, *Scilla campanulata*; 6, *Euphorbia pilosa*.—Salop. 1, *Cattleya Mossiæ*; 2, *Odontoglossum triumphans*; 3, O. crispum; 4, O. cirrosum; 5, O. odoratum; 6, O. Coradine; 7, *Cypripedium Mastersonianum*.—H. J. W. *Oncidium prætectum*.—C. Sussex. 1, *Veronica gentianoides*; 2, *Hemerocallis* variety; 3, *Staphylea colchica*; 4, *Prunus sinensis*, double white variety; 5, *Symphytum officinale*; 6, *Lonicera* species.

NECTARINE FRUITS CRACKING: Cork. The fruits may crack at the stage yours have done from a variety of causes. The most common cause is that of allowing the border to get too dry, and then flooding it with water, which has the effect of making the fruits to swell too quickly, and the skin being unable to expand at the same rate, cracking ensues. It is good practice to allow the trees to grow rather more slowly during the time when the "stones" are forming within the fruits, lessening the atmospheric temperature in the house for this purpose by the employment of freer ventilation. We do not know a variety of Nectarine bearing the name Princess of Wales. There is a Peach known by that name, but we suspect the Nectarine you have in cultivation is that known as Prince of Wales.

PEACHES INJURED: Peach. The injury is due to gumming, which has resulted owing to the presence of canker in the stem. The canker is too deeply seated to be easily cured. When gumming appears on the stem or branches, the tree ceases to thrive and should be rooted out.

PEAR LEAVES INJURED: A. C. C. The mischief has been caused by the Pear-leaf blister-mite. Collect and burn the injured leaves and fruits. Drench the trees next winter with Bordeaux mixture.

SLUGS AND SNAILS: A. S. Starlings, thrushes and blackbirds are the principal natural enemies of slugs and snails, but toads and frogs also kill a large number of these pests. Toads hibernate during the winter, and often hide themselves during the daytime, therefore they may be present in a garden, and yet escape notice. Cats will sometimes attack toads, but not often. Light boards laid along the sides of the beds in a garden have been found to be the most useful traps for slugs. In one garden where this means of capture was adopted, upwards of a thousand slugs were found beneath the boards each morning, and by this means they were ultimately exterminated.

TOMATO LEAVES: J. B. You must send better specimens. The few leaves that were wrapped in paper were quite insufficient for proper investigation. Cut off a shoot with leaves, and pack them in damp moss in a wooden box.

VINE LEAVES INJURED: W. M. There is no fungus present and the plants do not require spraying with a fungicide. They have the appearance of injury by fumigation. Apply more ventilation to the structure in which they are growing.

WILD FLOWERS: W. M. The most suitable work for use in identifying British native plants is Bentham and Hooker's *British Flora*. This is published in two parts, one consisting entirely of illustrations. They can be obtained from our publishing department, price 9s. 4d. each volume, free by post.

HARDY RHODODENDRON
HYBRIDS.

THE various Rhododendron hybrids cultivated in gardens have been derived from few species, but the parents, though few in number, possess great divergence in the colour of their respective flowers. Repeated crossing and intercrossing have resulted, therefore, in the raising of varieties whose flowers vary from pure white through all the shades of pink, lilac, and red to deep crimson and purple. Up to the present time no hardy yellow-flowered Rhododendron has been raised, though the use of such species as *R. campylocarpum* and *R. Dalhousiae* may eventually furnish this colour. A good yellow flower is hardly probable just yet, for it takes at least seven years from the seed before the inflorescence of a Rhododendron plant is produced, and perhaps seven or ten years more must elapse before the immature or weak yellow colour in the first seedling can by recrossing be developed into the full, rich shade that is desired. Blue, or rather purplish blue, has been obtained in some varieties to a certain extent, but the colour was considered unsatisfactory and the varieties have not been perpetuated by the raisers. A Rhododendron with flowers of the blue colour of *Gentiana acaulis*

or of a deep blue Hyacinth would be an acquisition, but this is scarcely probable, as the intermixture of purple in most of our hardy Rhododendrons is too strong to be entirely eliminated. The standard of perfection in a hybrid Rhododendron is a free-branching habited plant having good foliage and conical trusses of closely-set flowers, borne in an erect manner well above the foliage. The colour of the petals should be true, and should be either one which pleases when closely inspected or which is effective when seen from a distance. For instance, shades of pink or rose are pleasing when seen near, but others of red and crimson tints do not impress one greatly when closely inspected, although seen at a distance of, say 30 yards or 50 yards they surpass in their beauty those of every other colour.

The species that have been used in the raising of the majority of our hardy hybrid Rhododendrons are *R. arboreum*, *R. campanulatum*, *R. catawbiense*, *R. caucasicum*, and *R. ponticum*. Other species have also been used in recent years, but the above mentioned are those that were first crossed, and in nearly all the hardy hybrid Rhododendrons the influence as parents of some one or another of these can be traced.

Rhododendron *arboreum* is a native of the Himalayan region, and its seedlings vary considerably in the colour of their flowers, but the type has petals of a bright, blood-red hue, and bold, thick leaves, green, or sometimes brownish-green above, and silvery beneath. It develops into a tree 30 feet to 40 feet in height: it is not hardy in this country, except in a few favoured parts in the south and west. Its influence, however, on our hardy Rhododendrons can be clearly traced, as the majority of the best red and pink varieties are indebted to this species for their colouring. The first hybrid of which there is any authentic record is *R. altaclerense* x (*Botanical Magazine*, t. 3, 423), obtained by crossing *R. arboreum* with *R. ponticum*, and which bears bright-scarlet flowers. It bloomed for the first time in 1835 at Highclere, where it was raised. This was closely followed by *R. nobleanum* x (*R. arboreum* x *R. caucasicum*), a hybrid having crimson-coloured flowers that open early in the year. The raising of these first hybrids is said to be due to the then Lord Carnarvon, who suggested that if *R. arboreum* was crossed with some of the hardy species the beauty of the one might be combined with the hardiness of the other, and the results have proved the value of his suggestion. Other hybrids that show the influence of *R. arboreum* are *atro rubrum*, *Russellianum*, *Grand Arab*, *Sun of Austerlitz* (red); *Lady E. Cathcart*, *John Henry Agnew* (pink); *Baron Osy*, white with dark spots; *Blanche Superbe*, &c.

R. campanulatum is also a native of the Himalayan region, and usually makes a large bush 6 feet or more in height, but plants have been known to reach a height of 20 feet or more in this country. The flowers are of a lilac colour, with purple pots, and the leaves are nearly oblong in shape, and blunt, as a rule, at both ends. It has not been used much for hybridising, its two most typical progeny being *campanulatum pictum*—usually classed as a variety, but more probably a hybrid—bearing pale-lilac campanu-

late flowers with reddish spots; and *Jean Stearn*, with pure white petals marked with purple spots. This latter is a beautiful variety, but it is rather tender and a shy bloomer.

R. catawbiense was first introduced to this country from the United States in 1809, and has had more influence on the present race of hardy Rhododendrons than any other. It is one of the hardiest of the genus, and, flowering in late May and early June, its descendants are less liable to injury by spring frosts than the early-flowering varieties. The flowers are lilac or purplish in colour, and the leaves are variable in size and shape; usually from 4 inches to 6 inches in length, deep green in colour, soft and smooth to the touch, and, as a rule, turned downwards at the margins. It is a vigorous grower, and attains to a height of from 8 feet to 20 feet with age, with a proportionate diameter. The influence of this species in the hybrids has been altogether for good, as it has given hardiness, freedom of flowering, and bold, vigorous foliage. The inflorescence is borne in close, upright trusses, and a selection of hybrids of the *catawbiense* strain comprises those with flowers of practically all the colours to be found in the genus. The only defect—if it be considered one—in the *catawbiense* hybrids is that the lilac or purple colouring of the parent has been largely transmitted to the seedlings, so that all the red or crimson hybrids have a magenta or purplish tint. This, however, is not a glaring fault unless the flowers are seen near to those of a pure scarlet colour. The magenta-crimson shades of some of the *catawbiense* hybrids produce wonderfully good effects a little distance away. A few of these hybrids with their colours are *album elegans*, *a. triumphans*, *Minnie*, *perspicuum*, and *Madame Carvalho* (white); *delicatissimum*, *luciferum*, and *Lady Hillingdon* (blush); *Everestianum*, and *fastuosum flore pleno* (lilac); *B. W. Elliott*, *Lady Armstrong*, and *roseum elegans* (rose); *atrosanguineum*, *Charles Dickens*, *H. W. Sargent*, *Sigismund Rucker*, *Mrs. Milner*, and *Caractacus* (red and crimson); *purpureum elegans* (purple, &c.).

R. caucasicum was first introduced from the Caucasus in 1803. It is a dwarf species rarely reaching more than 3 feet in height, and thriving well under trees. The flowers are borne in loose trusses, and are rose-coloured on the outside, pinkish-white within, with a cluster of greenish spots in the throat. They open about the beginning of May. The hybrids that most strongly show the influence of this species are characterised by a dwarf and free-blooming habit, such as in the varieties *Prince Camille de Rohan*, *venustum* (*Jacksoni*) and *Zealand*, all the flowers of which are of rose or pink shades. Besides the few hybrids which show the dwarf habit of *R. caucasicum*, there are many others which have resulted from crossing it with *R. arboreum* and *R. catawbiense*, and the majority of these have never been named. Most of them come into bloom from the beginning of April to the middle of May: they are strong, free growers and profuse bloomers in districts where they are not injured by spring frosts. In colour the flowers range from pinkish-white to crimson, and every year specimens from various parts of the country, chiefly from

the warmer districts, are sent to Kew and other places for naming, but not one in a dozen has ever been named, though some of them are worthy of this distinction.

R. ponticum is rather peculiar in its distribution, being found in Spain and Portugal and also in Asia Minor, but nowhere between these countries. It was first introduced into England about 1763 from Asia Minor, and is now common all over the country, where its lilac or purple flowers are rather too evident sometimes, though for certain purposes, such as cover-planting, &c., it is invaluable, as it is never eaten by rabbits or other animals. The hybrids which show *R. ponticum* most strongly are *album grandiflorum*, Mrs. John Clutton, Mrs. Tom Agnew, *multi-maculatum*, *pictum*, and *Mum* (white); Viscount Powerscourt, and Michael Waterer (red), &c.

There are, however, many hybrid Rhodo-

which are the parents of the bulk of our hardy Rhododendrons, there are four other species that of late years have been used for hybridising. These are *R. Griffithianum*, *R. Fortunei*, *R. Smirnowi*, and *R. Thomsoni*. *R. Griffithianum* and its hybrids were described in the *Gardeners' Chronicle* for April 21st, 1906, p. 242.

R. Fortunei is a native of China, and is a free-growing species, with sweetly-scented seven-petalled flowers, each about 3 inches across, white, faintly tinged with pink. Many hybrids have been raised from this species, but none of them is of great importance, probably the two best are Mrs. Thiselton-Dyer and George Thiselton-Dyer, the latter having deep-rose coloured flowers with brownish spots, the former having much the same colouring but paler.

R. Smirnowi is a native of the Caucasus, and is a dwarf, bushy species with large

mentioned species and their hybrids have been re-crossed with the older strain, we may expect a wider range of colouring and considerable variation in both foliage and habit. With the possible exception of *R. Smirnowi*, the present hybrids of the four last-mentioned species are rather tender, but by combining them with the older race a new strain will be evolved combining the best characters of both types. *J. Clark, Bagshot.*

SINNINGIA HELLERI.

THIS most charming Gesneriad is uncommon. It was introduced to the Garden of the Royal Horticultural Society in 1826, and was figured as *S. velutina* in the *Botanical Magazine*, tab. 4212. In that work it is said to be the handsomest of the genus *Sinningia*, but in this statement the garden *Gloxinia*, now a *Sinningia*, was not taken into account. Though not so showy as the *Gloxinia*, this species is exceedingly attractive. It is best grown in a stove, but may be used for the decoration of the greenhouse while in flower. The two or three stems, into which the plant usually breaks, are quite short, each producing half a dozen dark, olive-green leaves, ovate-oblong in shape, and the finest nearly 1 foot long. The flowers open at any one time may number up to nearly two dozen on the same plant. The calyces are reddish in colour, the corollas, which measure over an inch across the mouth, are creamy-white, contrasting well with the dark green of the leaves. The plant is a native of Brazil, and our illustration at fig. 143 has been reproduced from a photograph taken of the smallest among a number of plants which flowered during the spring in the Cambridge Botanical Garden. The seeds were received from the Botanical Garden of Prague. *R. Irwin Lynch.*

[A new species (*Sinningia Regina*) having lilac-coloured flowers, was illustrated in these pages on Sept. 17, 1904, p. 201.—Ed.]

FIG. 143.—*SINNINGIA HELLERI*, AS CULTIVATED IN CAMBRIDGE BOTANICAL GARDENS: FLOWERS WHITE, WITH REDDISH CALYCES.

dendrons which do not show a predominance of any one species in them, and the exact origin of which it is difficult, or even impossible to trace. Such sorts as Baroness Rothschild, Baron Schröder, B. W. Currie, Countess of Tankerville, Duke of Connaught, Joseph Whitworth, Kate Waterer, Mrs. John Penn, Mrs. Tritton, and many others can scarcely be traced to any of the species I have mentioned. When one remembers, however, that it is now over 50 years since the first hybrid Rhododendrons were raised, and that crossbreeding has been going on ever since, it is not surprising that their origin should be difficult to determine. The possible combinations of the five species mentioned above are enormous, and no two seedlings are exactly alike. The total number of hybrid Rhododendrons raised is very large, though probably not 5 per cent. of them have been named.

Besides the five species mentioned, and

leaves, deep-green above, and covered beneath with a whitish, wool-like tomentum. The rosy-lilac flowers measure 2 inches to 3 inches across, and they are prettily fringed at the edges. The few hybrids that have been raised are of second-rate importance, but the influence of this species, if continued, will probably result in a good and very hardy strain.

R. Thomsoni is one of the Sikkim species, but it is a rather tender plant except in favoured districts. The leaves are broadly ovate, and the tubular flowers are of a deep blood-red colour, borne in loose trusses, and opening in April and May. The best hybrids are *Ascot* brilliant, with flowers of a vivid scarlet colour: the plant is rather tender; *Luscombei* (*R. Thomsoni* × *R. Fortunei*) with rosy-red, tubular flowers 3 inches across; and *R. F. Thiselton-Dyer*, deep-rose with a dark mark in the throat.

In the course of time, when these four last-

NOTICES OF BOOKS.

THE BOOK OF VEGETABLES.* By Allan French.

THIS is a practical handbook and planting table for the vegetable gardener. In many respects it is as useful to gardeners in this country as to those in the immense area of the United States, with its great differences in climate, altitude, and soils. It contains numerous shrewd remarks on garden practices, and many of them are much called for here by those persons who may be desirous of growing vegetables better than they have done, but have not much knowledge of the way to set about the work. In the preface the author tells us how to prepare the land and sow seeds, whether the garden is a small garden under spade cultivation, or a large one requiring horse labour for the heaviest kinds of work. The dates for seed sowing in different latitudes are stated, allowing six days' difference for each hundred miles of latitude—pretty much as we do in this Island. He is very insistent about the "summer mulch," that is, the loose crumb left on the surface of the ground after the seed is sown and drills filled in. For each kind of crop directions are given as to the proper distance of the rows from each other, determined by the height and spread (whether above or below ground) of the plants. Many hints are given about the sowing of seeds, depth of drills, use of manures, farmyard and commercial, and the thinning of seedlings. The list of vegetables mentioned is very comprehensive, and it contains many sorts besides those familiar to us in this country. All are alphabetically arranged, and thus easy of reference. The botanical and popular names, if any, are given, also the English garden names of most of the vegetables and vegetable fruits.

PHAIUS SPECIES AND HYBRIDS.

SOME of the more interesting examples of Orchid hybridisation are represented in the illustration (fig. 144), which clearly shows the characteristics of the parents reproduced in the offsprings. The flower numbered 2 is *P. Blumei*, var. *Sanderianus*; No. 3, *P. simulans* (better known in gardens as *P. tuberculosus*); No. 5 is *P. X Norman*, the offspring raised from the above-mentioned species. No. 4 represents *P. X Clive*, derived from the inter-crossing of *P. simulans* and *P. X Norman*, and thus representing three-fourths *P. simulans* and one-fourth *P. Blumei*. In this variety the sepals and petals have become broader and creamy-yellow in colour. The lip is very much broader and shorter, lighter in colour, and having a distinct tuft of hair like bristles in the throat, in every way illustrating

FRUIT PESTS OF THE SEASON.

"Don't mention it" is the protest, uttered half in jest, but still with the shade of an old superstition clinging to it, when one speaks with gratification of immunity from some common trouble. Quite recently I ventured to remark in these columns that Apple and Plum trees were free from aphides. In my last article, however, I had already occasion to notice the arrival of the Plum aphid, and now it is my unpleasant duty to mention the appearance of its close relation, the Apple aphid, with various other pests. At present the aphid attack is comparatively slight, probably because the recent very cold and wet weather has not been propitious to reproduction by the viviparous females. But perhaps before these remarks are in print there will have been some warm weather,

Seedling, Lane's Prince Albert, and Bramley's Seedling are practically exempt at present. Nearly all were subjected to a severe and persistent attack last season.

With much regret I notice more damage from the caterpillars of the winter, bud, and pith moths than has been seen for some years in my oldest plantations of Apples. From Codling moth my trees have enjoyed a rare exemption, and leaf-eating caterpillars have not previously been very numerous. But those named above, and particularly the larvæ of the winter moth, are doing much damage to some varieties, and are more or less in evidence on nearly all. Bismarcks have the worst attack of these as of all other pests. They are bushes on the Paradise, and they are growing in the lightest part of the plantation, where the soil or sub-soil (a running

FIG. 144.—PHAIUS SPECIES AND HYBRIDS.

the influence of the pollen parent, *P. simulans*. No. 1 is *P. X Harold* (*P. Blumei* $\times$ *P. X Norman*). Here is seen a similar reversion to the *P. Blumei* parent as is seen towards *P. simulans* in No. 4. The tube of the labellum has become longer and less broadened at the apex, and the sepals and petals are narrowed and much longer than in *P. X Norman*. There has been some variation in colour amongst seedlings from this cross, but the general characteristics of the plants have been the same. It may be of interest to note that in the foliage and habit of growth also the hybrids are intermediate in character between their parents. These hybrid Orchids are useful for decorative purposes, and thus are deserving of general cultivation in gardens where a demand exists for flowering plants during the months of February and March. H. J. C.

and some feats in fertility of reproduction by these marvels of fecundity. With me the attack is worst on Pond's Seedling Plums, and next on Monarch. Early Rivers and Czar have a little of it, but Victoria and Gisborne's none, or none worth mentioning. Spraying with a strong decoction of quassia and soft soap has been done, but most of the pests were protected in curled leaves.

On most varieties of Apples there is a slight show of aphid. It is worst on soft-leaved varieties, such as Bismarck, The Queen, Domino, and Newton Wonder. There is not much on Worcester Pearmain, Beauty of Bath, Mr. Gladstone, Irish Peach, Cox's Orange Pippin, Early Julyan, Duchess of Oldenberg, or Warner's King; while King of the Pippins, Lady Sudeley, Blenheim Pippin, Ribston Pippin, Fearn's Pippin, Potts'

sand in which drainage has not been very successful) does not suit them.

As for the pith moth caterpillar, it was hoped that persistence, year after year, in cutting off all infested spurs and ends of shoots, had nearly extirpated it, as there was hardly any of it last year. Now, unfortunately, there is much on many varieties.

Before leaving the subject of insect pests, it seems desirable to mention a point in reference to the Black Currant mite which may not have been noticed by some growers. My plan, since an attack commenced among bushes quite mite-free when I bought them (raised in a nursery where there had never been any "big bud") has been to dig up every badly-infested bush, replacing it by a fresh one, in the winter, while picking off every isolated big bud found among

the rest of the bushes, going over them twice in the season. This spring I noticed, just when the leaves of sound buds were expanding, that many others, chiefly on stems near the ground, were ineffectively struggling to open, after having swollen nearly to the bursting point. Microscopical examination of several of these showed that they contained mites. They had been missed in two inspections, but betrayed themselves very distinctly when they had swollen in the effort to expand. My suggestion, therefore, is that growers should make a point of having every bush examined at this stage of seasonal development, and every non-expanded bud picked off and burnt, though without neglecting an earlier operation.

This unfortunately wet season, it is to be feared, is developing fungus pests in an extraordinary degree. I have found brown rot (*Monilia fructigena*) among a few Plums, all in one part of the plantation—an attack never noticed before.

Far worse is a bad attack of powdery mildew (*Sphaerotheca mali*) on some varieties of Apples, and a slight one on others. Until last season, no attack of this fungus was noticed, and then it was almost confined to Allington Pippin. All the whitened shoots were cut off and burnt, and it was hoped that the malady was suppressed; but this season it is in evidence more or less in all parts of my oldest Apple plantation. It is far worse on Bismarck than on any other variety, Allington coming next, then Cox's Orange, and Blenheim Pippin, growing close to Allington Pippin. Some varieties, including Worcester Pearmain, Irish Peach, Lady Sudeley, Stirling Castle, Lane's Prince Albert, and Bramley's Seedling are free from the attack.

American blight has never appeared in the plantation before this spring, and a few days ago I found traces of it on two trees, and may find it on more. There was none on the farm until it came on some crab stocks. All the affected parts, so far as could be seen, were cut off and burnt at once, the stocks being reduced to stumps; but ever since it has been very troublesome, requiring frequent dressing, in the piece of nursery ground in which young trees are raised, but has been kept out of all Apple orchards until this season.

Scab was extremely damaging to Apples and Pears last year, and there is every reason to expect a bad attack again this season, although the trees were sprayed with copper sulphate alone just before the buds burst. Already I find it on the leaves of a few varieties, especially the much afflicted Bismarck. There is also a little brown rot among the Apple trees.

Spraying with Bordeaux mixture and Swift's lead arsenate paste is now in progress among the Apple and Pear trees grown here, in the hope of checking scab and brown rot, while also poisoning the food of the winter moth, bud moth, and other leaf-eating caterpillars. The fungicide will be applied again two or three weeks later, with or without the lead arsenate, according to circumstances.

It may be useful to announce that Swift's lead arsenate paste, a well-tried American preparation, is supplied in this country now for the first time by Messrs. Strawson, of Queen Victoria Street, E.C., and possibly by other sellers of spray fluids and materials. It is much safer than Paris green in relation to the foliage.

If the wet weather continues, an extension of canker may be expected, though no signs of fresh attack have yet been noticed. King of the Pippins, Ribston Pippin, and Potts' Seedling are the only varieties very badly affected in my market plantations, though one of two Cellini Pippins in my home orchard has been destroyed by it, while the other is badly crippled.

Among Pears, grown merely for home consumption, the only noticeable fungus disease is scab, which is rampant on Glou Morceau and Marie Louise, but not very bad on any other varieties. It is already showing on the leaves

of the two varieties named, and some of the small fruit on a third variety seems to be affected by it. All Pears have been sprayed with Bordeaux mixture.

Apart from a slight attack of aphid on a few Black Currants, and mite among these and cobnuts, no appearance of pests among bush fruits has yet been noticed.

This account represents only my own plantations. In some other places a bad infestation of the Apple sucker appears to be in evidence; but I have not seen this pest this season, and it may be concluded that the time for the beginning of an attack is now past. In 1905 there was an overwhelming infestation of this extremely damaging insect; but either spring or subsequent winter spraying appears to have annihilated it. At any rate, not one was seen last season, and none has been found this year. *A Working Grower.*

THE GENUS ENKIANTHUS.

(Continued from page 311.)

E. quinqueflorus.—Usually a bush 1-1½ metres high, more rarely a small tree 5-6 metres tall. Leaves oblong or obovate-oblong, acuminate, 5-10 cent. long, entire, coriaceous, shining, strongly reticulate on both surfaces. Flowers usually in umbels of five, stalked, drooping, issuing several together from a bud enclosed in imbricate scales, of which the inner ones are lengthened into stalked oblong-spatulate or linear coloured bracts. Calyx-lobes lanceolate-ovate, varying in length and breadth. Corolla about 1 cent. long, usually pink or peach-coloured, often with white lobes; corolla-lobes obtuse, more or less recurved or spreading. Fruits angled.

Native of Hong Kong and South China, also commonly cultivated by Chinese. First flowered in this country in Mr. Knight's Royal Exotic Nursery, Chelsea, in 1814, from whose specimens it was figured in the *Botanical Magazine*, t. 1649.

E. quinqueflorus, Loureiro in *Fl. Cochinch.*, p. 277.

E. reticulatus, Lindley, *Bot. Reg.*, t. 884 and 885.

E. uniflorus, Benth (Hook, Lond., *Journ. Bot.*, i., p. 489) originated in a mistake and is *E. quinqueflorus*.

E. quinqueflorus, Lour., var *serrulatus*, E. H. Wilson (var. nov.) Differs from the type in its much less coriaceous, finely serrulate leaves, more or less villous on midrib below, and flowers of the purest white.

Hupei, Wilson, No. 921 Henry, No. 5,475! Yunnan, Henry, No. 11,009!

This is a very distinct continental form. My specimens were collected from a tree 6 metres high, growing in a ravine, south of Ichang, at about 4,000 feet. Seeds were gathered from this tree, and the plant is in cultivation with Messrs. Veitch.

Henry describes his 5,475 as a shrub 8-8 feet high. His 11,009, from the hills south of Meng-tze, alt. 5,000 feet, a bush 8 feet. This latter specimen is in fruit, and has the primary and secondary veins on the under side of the leaf densely covered with villous hairs.

PALIBINI (l. c.) refers Henry's 5,475 to the type *E. quinqueflorus*. Diels (Engd. Jbhrb., xxix., p. 503) refers this same number to the widely different *E. chinensis*, Franchet.

E. japonicus.—Usually a bush 1-2 metres high, with smooth, light red or yellowish bark. Leaves more or less lanceolate with petiole 2½-4 cent. long, 1-1½ cent. broad, finely serrulate, reticulate, villous at base of midrib on the underside. Flowers in umbels of 5-10 on spreading filiform pedicels 1-2 cent. long. Calyx-lobes triangular-acuminate, whitish. Corolla white, 6 mm. long and broad.

This is one of the best known species from Japan, having been first discovered by Sir Rutherford Alcock in 1859, near Nagasaki. It appears to be rather widely spread, having been found in the

island of Nikko, on Fusi-yama, and in the neighbourhood of Tokyo. In autumn the foliage assumes a bright yellow colour. *E. japonicus* was first introduced into cultivation in this country by Messrs. Standish, about 1869.

E. japonicus, Hook., f. *Bot. Mag.*, t. 5822 *Andromeda japonica*, Miquel l. c.

E. campanulatus.—A small tree 6-10 m. high; leaves elliptic-ovate, sub-acute, aristate-serrulate, narrowed at the base into a short glabrous or slightly hairy petiole, more or less reddish hairy below with a few scattered setulose hairs on both surfaces. Flowers numerous, racemose or racemously-umbellate. Corolla 1 cent. across, shortly campanulate, 5-lobed, dark red with 8 dark nerves on the tube answering to each lobe. Capsule ovoid, 5-8 mm. long.

This is the finest of the Japanese species and one of the best of the genus. It is very similar to *E. himalaicus*, but is easily distinguished by its longer and different-shaped fruits and much more finely-toothed leaves. A native of Northern Japan and the vicinity of Hakodadi, where it has been found by various collectors. In the southern provinces of Japan it is apparently only cultivated. It was introduced into cultivation in this country by Messrs. Veitch through the late Chas. Maries.

E. campanulatus.—Nicholson in *Dict. Gard.*, i., p. 510. *Bot. Mag.*, t. 7059.

Andromeda campanulata, Miquel, l. c., Maxim. in *Mel. Biol.*, viii., p. 618. Franchet and Savatier *Enum. Plant., Jap.*, i., p. 284.

E. himalaicus.—A large bush or small tree, often 7 metres high. Leaves varying from lanceolate to broadly obovate-elliptic, usually narrowed to both ends, acute or obtuse, serrulate, reddish hairy below. Flowers in terminal, pendulous, racemose or sub-umbellate clusters of 20, or even more. Pedicels 2 cent. long, slender. Calyx-teeth lanceolate or ovate-acute. Corolla 8-15 mm. broad, widely campanulate; colour varying from yellowish-salmon to orange-red, with numerous dark-red striae; corolla-lobes variable in size, erect or slightly reflexed, darker in colour than the rest of the corolla. Style, stamens, and ovary more or less clothed with short, setulose hairs. Fruit nearly globose, about 6 mm. broad.

This species is the most widely spread of the genus, ranging as it does from Sikkim, Bhotan, and East Nepal to Western China, where it is abundant on precipitous cliffs from 8,000 feet to 11,000 feet. With its wealth of flowers in late June, and its wondrous autumnal tints, *E. himalaicus* is one of the most strikingly beautiful plants of the mountains of Western China.

It first flowered in the Edinburgh Botanic Gardens in June, 1879, and is figured in the *Bot. Mag.*, tab. 6460, from material supplied by Prof. Balfour. The Himalayan form is tender in this country, and very rare in gardens. The Western China form has been introduced into Messrs. Veitch's establishment, and will probably prove hardier than the Himalayan form.

E. himalaicus.—Hooker, f. et Thomson, in Kew, *Journ. Bot.* vii., p. 125, t. 3.

Rhodoraceæ Griffith, *Posthumous papers*, vol. ii., p. 148, n. 717; and *Rhodora deflexa* Griff., l. c., p. 187, n. 969. *E. H. Wilson.*

(To be continued.)

LILIUM AURATUM AT TITTENHURST.

For the illustration (fig. 145) of *Lilium auratum* and its varieties flowering last summer, in the borders at Tittenhurst, Sunninghill, Berks, we are indebted to Mr. Joseph Timson, the gardener at that place, who informs us that the plants grew to a height of from 9 to 10 feet, and that the air was perfumed with the flowers. *Lilium auratum* is familiarly known as the golden-rayed Lily of Japan, and it has been stated that more than 5,000,000 bulbs of this and other species of *Lilium* are

exported every year from that country. There are numerous distinct varieties of *L. auratum* that are improvements upon the type, amongst which the following are best known:—*Platyphyllum* is larger and finer in all respects than the type, the flower being from 10 to 12 inches across. The segments generally are studded with crimson chocolate spots. *Pictum* is similar in form to the type, but the flowers are tipped with crimson at the ends of the yellow rays. *Rubro-Vittatum* has flowers that are studded with purplish crimson spots. *Wittei*, a white variety, has yellow bands without spots. *Virginale*, a large white flower, with a yellow band in the centre of each petal, is studded with white spots. A descriptive and illustrated article upon the Tittenhurst gardens was published in our issue for October 22, 1904.

quire no further attention until the autumn, except watering, tying, and the stopping of the growths. The later batch of forced Teas, Noisettes, &c., can now be removed into a cool-house, where they should be kept dry at their roots. After a few weeks, and when they show their new growths, cut out the exhausted wood, prune slightly back, afford a top-dressing, and keep them well syringed, when a further crop of good blooms may be expected. The Hybrid Perpetuals in pots can now be planted outside as soon as they are sufficiently hardened off: this type of Rose blooms freely but once in pots, therefore they will occupy room to no purpose if still allowed to remain in the plant-house. Roses on their own roots plunged outside will now be growing freely, and during this showery weather an occasional pinch of some approved fertiliser

now be completed. Endeavour to exterminate all insect pests, which, if combated early in the season, do not cause nearly the same amount of trouble later. Beds of Roses, either of standard or dwarf kinds, should be carefully examined, and in order that any suckers from their roots or stems may be removed.

Cuttings inserted in the open ground last October will now be mostly rooted, and a good number will be making top growth. Pinch back any of the long, straggling shoots, and thus induce a bushy habit of growth. It is better to defer transplanting these until the autumn. All outside Roses will be much benefited by an occasional mulching of manure and a top-dressing of dissolved bones applied at the rate of 4 oz. to the square yard in moist weather. These dressings will be of great assistance in pro-

FIG. 145.—*LILIUM AURATUM* AS CULTIVATED IN THE GARDENS AT TITTENHURST, THE RESIDENCE OF T. H. LOWINSKY, ESQ.

THE ROSARY.

CULTURAL NOTES FOR JUNE.

THE new growths of Roses generally have been much injured by late frosts, and even late as is the season, I should be tempted to cut the injured growths back to sound wood, for if the plants bleed a little, not much harm will result, and they will soon recover. Finish the planting of Tea and other sorts of Roses from pots, and afterwards well mulch the surface of the ground and make certain that all are carefully secured, especially standard plants, to proper stakes. All autumn and spring-grafted plants still in the houses or frames should now be removed out-of-doors and plunged; they will re-

will be helpful to them. Ply the hoe between the rows of seedling briars when the latter are well through the ground and also amongst all planted-out Roses. Standard Briars are now beginning to break into growth, and at the end of this month, or early in July, three of the stronger shoots nearest the top of the plant should be selected, and all below them removed. If a few good ripened scions of Teas and Noisettes can be had from under glass, and at the same time a few well-matured shoots on briar stocks, budding can be practised during this damp weather with every chance of success. However, budding generally should not be practised before the end of this month or early in the next. All work amongst budded, standard-and-dwarf Roses, including staking, tying, &c., should

be practised during this damp weather with every chance of success. However, budding generally should not be practised before the end of this month or early in the next. All work amongst budded, standard-and-dwarf Roses, including staking, tying, &c., should

ducing best quality exhibition blooms. When blooms or buds have been retarded by ungenial weather, it is a difficult matter for the grower to determine what the quality of his blooms are likely to be at a given date. To guard against disappointment, it is necessary to have a good reserve of duplicates of the sorts intended to be shown. Trade growers and successful amateurs usually obtain their best exhibition blooms from maiden buds on the briar, but these are not usually available or ready for exhibition till well on in the season. To obtain the best results the plants must be given plenty of nourishment in the form of mulchings or top-dressings, from the time the bud is well developed until it begins to show colour. J. D. G.

THE COUNTRY GARDEN.

WELL known as they are, and well written up as they are, the Japanese Chrysanthemums for early flowering out of doors have not found their way into country gardens so generally as they should, by a long way. We have nothing like them for sustaining an effect all through the autumn if they be well massed. It is a mistake, I think, to use them merely as plants here and there in a mixed border. To secure their full decorative value they should be made a prominent feature in the autumn garden. A well-thought-out colour scheme, restrained as to the number of colours used, but as brilliant as may be; such, for instance, as crimson, and gold and yellow, with a few of the brighter and redder bronzes. This is, in my humble opinion, the most striking and effective of all combinations. Some really good varieties would include Goacher's Crimson, Kuroki, Mytchett Crimson, Fleur Rouge, Crimson Marie Masse, Orange Child, Horace Martin, Guinea Gold, and Piercey's Seedling.

Every year, too, the single varieties are becoming greater favourites; these should certainly find a welcome place in the country garden, especially where a good supply of cut flowers has to be maintained. Elegans and Felix are in red and gold, M. Richardson is a bright pink, and so is Lady Smith. The old favourite, Mary Anderson, is always charming, and so also is the sulphur-yellow sport from it, known as Miss A. Holden. Well-rooted cuttings may be secured at the present time, but they should be established at once. I never disbud nor stop, as I think that for garden use a fine decorative display is of greater moment than large individual flowers. Even thus treated, however, many blossoms will measure 4 inches across.

A good deal has been written of late concerning the hardihood of the Camellia. I have seen it stated that it is as hardy as the Laurel, so long as it is not growing in a low-lying or damp locality. It is, at any rate, a delightful subject to experiment with; but to experiment with specimens that have been unduly weakened by artificial heat will need caution. They will have to be hardened by thorough ripening out of doors during the summer months. If necessary, they should be afforded the protection of a cold house the following winter, brought out again when fear of frost is over as a necessary precaution after this shelter, and then planted out in soil that has been well worked; henceforth, to be left undisturbed. I must confess English gardeners are not given to experimenting one half as much as they should; not only is it one of the most interesting and delightful phases of gardening, but much good may come of it. A hundred years ago, and more, that excellent old gardener, Philip Miller, pleaded for hardier and more vigorous treatment of those plants that in reality did not need high temperatures and coddling. The same plea would be appropriate to-day—we are still coddling and making tender, plants that do not need it. There is a real pleasure and interest in experimenting and finding out just how hardy are many of the subjects to which we are affording considerable heat. We realise that a plant, say, comes from India, and we imagine it cannot withstand our climate. If it should happen to hail from the Himalayas, the chances are it is absolutely hardy and able to withstand greater cold than it will ever experience in England, and the same may be said of natives of Japan and China. In many cases our efforts should exercise themselves in trying to obviate the evils of excessive dampness and moisture during the late autumn and winter. In a large number of cases damp will kill, but cold unaccompanied with excess of moisture may leave plants unscathed. Perfect drainage and raised beds, sometimes rockwork edgings, all prove of the utmost benefit, and the experimenter will do well to use them extensively. I may say that many plants are far more amenable to hardy, out-of-

door treatment in the rock garden than in any other position. Some gardeners will say that it is not worth while to trust plants of doubtful hardihood to the chances of a hard winter. I cannot agree with this; the careful training and acclimatising of plants to withstand even severe tests is, as I have already said, well worth the risk. I have been making some desperately sharp trials of plants by no means accounted hardy, in a cold greenhouse during this last winter, and I am delighted with the result. There is no need to say that the previous summer's treatment was a careful provision in the way of thoroughly ripening and preparing the plants for their winter ordeal. I contend you must even go back to the parent plants, and work up a supply from those that have never known a coddling and enervating treatment. Plants can be made wonderfully indifferent to even sharp changes of temperature if they are perfectly hardened by judicious training—but to excessive moisture, not so easily if it is foreign to their tastes.

I would greatly like to urge the increased beauty that is attained in the spring garden by making a freer use than rules in many places, of flowering plants that are not of a bulbous nature. Not for a moment am I decrying the beauty of the spring bulbous plants; but it is a pity, I think, to devote all the space to them to the exclusion of these others, and I would name *Orobis vernus*, *Doronicum austriacum*, *Erica carnea*, *Saxifraga ligulata*, and many others for free and generous use in the spring garden. *Practical Gardener*.

The Week's Work.

PLANTS UNDER GLASS.

By J. G. WESTON, Gardener to H. J. KING, Esq., Eastwell Park, Kent.

Richardia africana.—The latest batch of Callas should now be placed out of doors, and the amount of water afforded their roots gradually reduced until, as the foliage dies off, it is withheld altogether. After a rest, and before the roots become very active again, shake out the plants and re-pot them in a compost consisting of equal parts loam, leaf-soil, and manure from a spent Mushroom-bed, and then stand them in the open on a bed of ashes. This position will be suitable for them until towards the end of September, when they should be placed under glass and be allowed plenty of ventilation without much heat. If flowers of this plant are required before Christmas, place a number of the stronger crowns in a light house having an intermediate temperature, and ventilate the structure whenever possible to prevent the plants becoming drawn. If they are treated thus, and well provided with water and given a stimulant occasionally they will furnish flowers as desired. Another plan adopted by some cultivators is to shake the old soil from the crowns and to plant them in the open ground in a prepared border or trench, the latter being the better, as it allows water to be afforded easily in hot, dry weather. Under this system of culture the plants should be lifted and potted before the end of September, severing the roots and soil with a sharp spade some distance from the ball a few days previous to relifting them. After potting, shade the plants or place them behind a wall until they have recovered from the root-disturbance, but afterwards plant them in full sunshine.

R. Elliottiana.—This species requires rather different treatment to *R. africana*. The crowns should be started into growth in spring in the same manner as is practised with Caladiums, and they should be grown under glass all the season, "ripening" the plants in autumn and storing them during the winter in a perfectly dry condition in an intermediate temperature till spring.

Salvia splendens grandiflora.—The bright scarlet flowers of this decorative plant are very valuable during the dark, dull days of late autumn and winter, and especially pleasing in artificial light, thus making it a valuable subject for indoor decoration. Rooted cuttings should be re-potted directly they are ready for a shift, for

on no account should the plants be allowed to become stunted in their growth. Afford pots of a liberal size to the plants of early batches, as these will grow into very large specimens by the autumn. Place them outside on ashes, as soon as the weather permits. Pinch the points out of the shoots several times during the summer, and syringe the foliage each evening to prevent red spider, for if this pest is present the leaves will turn yellow, thus causing a check. In the warmer parts of the country *Salvias* can be planted in an outside border, and lifted in September as recommended for *Richardias*. Other winter-flowering subjects, such as *Eupatoriums*, *Moschosma riparium*, &c., succeed under similar treatment, but the pinching of the shoots must not be continued too late in the summer, otherwise many flowering shoots will be destroyed.

THE FLOWER GARDEN.

By A. C. BARTLETT, Gardener to Mrs. FORD, Pencarrow, Cornwall.

Lawns.—Now that we may reasonably expect to have drier and warmer weather, the lawn mower should be adjusted so that it will not cut so low as it is doing at present. By leaving the grass just a little longer it will to a great extent prevent "burning;" the grass will be much more pleasant to walk upon and have a better appearance. Make the change of adjustment gradually, and the lawn will not then be less tidy than before. Tennis lawns, croquet grounds, &c., on which games are played, must of course be kept closely mown. When in use have the mower frequently oiled, or complaints will be made that it "goes hard." During the dinner hour the machine must be put in a shady place. Any portions of the lawns which may show signs of "browning" will soon improve if lightly dressed with some quick-acting artificial manure, such as guano, mixed with finely-sifted soil, applying water afterwards. All grass verges and edges of flower beds and borders should be frequently clipped, and the grass around trees and those places where the mower cannot be used should be cut regularly, or yellow patches will result.

Mignonette.—The next few sowings should be made in a cool position, such as a border on the north side of a wall. The soil must be trodden firmly and raked fine. Merely cover the seeds with fine soil, and if the soil is dry, water it through a fine roset can. The earlier sowings will require watering during dry weather, or they will soon cease to produce flowers.

Gladiolus, *Galtonias*, &c., now require staking. This is often left until it is too late. The quality of the flowers suffer if the growths have been allowed to be blown down. Use short stakes at present and replace them with longer ones as the spikes require them. At this stage a mulching is beneficial.

Agapanthus umbellatus.—More use might be made of these stately flowers in the open flower garden. When planted out in a cool, partially-shaded soil they produce luxuriant foliage, and stouter flower stalks than when grown in flower pots. Although the *Agapanthus* is fairly hardy it is not advisable to leave the plants out for the winter even in Cornwall, as under these conditions they are late in starting into growth.

Biennials.—Seed may now be sown in the open border of such plants as Canterbury Bells, *Papaver nudicaule*, and *Hollyhock*. Where the latter plant suffers badly from the fungus disease, this may sometimes be prevented by sowing the seeds in a thoroughly prepared plot of ground, and after thinning out the seedlings allow some to remain and flower in the seed bed.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower to Sir Trevor Lawrence, Bart., Burford, Surrey.

Dendrobium Phalaenopsis has started to grow, and at first the young growths appear to be thin and weak, but if the plants are placed in a suitable atmosphere they will gain strength and swell rapidly. When the young shoots are a few inches high, numbers of young roots, push out from their base, and, before much rooting progress is made, those plants which require it should be repotted, and any not in need of re-potting should have the old material carefully picked out from between the roots and fresh compost afforded. The plants will thrive in

pots or shallow pans, but it is important that the receptacles should be small in proportion to the sizes of the plants. They should be filled to about one-half of their depth with drainage material, placing over this a layer of sphagnum-moss with some small crocks well mixed with it. Employ a compost consisting of three-parts fibrous peat and one-part chopped sphagnum-moss with some crocks of moderate size intermixed. The compost should be packed very firmly around the plants, as the roots prefer a hard material to one of a soft, spongy nature. If made quite firm, it will not retain moisture for any considerable length of time, and this will be conducive to the health of the plants. After repotting, place them in the hottest house, and, preferably, in a rather shady position, as when in the earlier stages of growth these plants have been exposed to plenty of sunlight, the young leaves have invariably become badly spotted and unsightly, but if towards the completion of growth the plants are placed in almost uninterrupted sunlight and an abundance of water is afforded at the root, the pseudo-bulbs will swell and become thoroughly consolidated, thereby enabling them to produce strong spikes and richly-coloured flowers. Until the plants are established in the new compost only a small quantity of water is necessary, but as roots become plentiful, and the growths make satisfactory progress, it may be afforded copiously. Other species of *Dendrobium* which require the same kind of treatment are *D. superbiens*, *D. bigibbum*, *D. lineale*, *D. Stratiotes*, and *D. Bensoniæ*. Such tall-growing plants as *D. Dalhouseianum*, *D. fimbriatum*, *D. f. oculatum*, *D. calceolus*, *D. clavatum*, *D. meschatum*, &c., make roots when the new growths are a few inches long, and will also require to be supplied with fresh rooting material at this season. The *D. macrophyllum* Veitchianum section appears to thrive best when placed in a light position near the roof glass of the intermediate house.

FRUITS UNDER GLASS.

By ALEXANDER KIRK, Gardener to J. THOMSON PATON, Esq., Norwood, Alloa, Clackmannanshire.

Young vines, which were raised from "eyes" last spring in pots or turves, and that have made growths 2 or 3 feet in length, will be in a fit condition for permanently planting into the vinery border. The border should be made up 2 feet 6 inches in depth, and it should be composed of chopped turf, adding to every 3 tons of the loam 1 cwt. of coarse-grade vine and plant manure, a liberal quantity of lime rubble, and should the loam be of a heavy nature, it may be improved by the admixture of some wood ashes. These ingredients must be well mixed together; it may be mentioned for the benefit of those who have not already made up the borders, that pieces of fresh turf, with the grass side down, should be placed over the drainage, proceeding afterwards to make up the border 3 feet in width and 2 feet in depth. Make the border very firm by beating and tramping as the work proceeds. Plant the vines 3 feet 6 inches apart on the top of this compost, spreading their roots well out, and cover with 6 inches of the finer parts of the compost. Make the soil over the roots moderately firm and tie the growths to the trellis. Apply a liberal soaking with warm water to settle the soil about the roots, keeping the atmosphere of the house moist and damp. Damp the paths and borders twice daily, and never apply fire heat. Shade the young plants from the sunshine if they appear to flag. Close the house early in the afternoon with sun heat. This system is to be preferred to that of planting in March vines that were raised in the previous year. If young plants are not in stock, they can be supplied by the nurserymen now equally as well as in winter.

Early Melons.—Plants carrying fruits which are now changing their colour require to be watered very carefully, as the roots are now less active than formerly. Do not restrict the water supply suddenly, but by degrees. Give just sufficient to keep the foliage green, never allowing it to flag. Keep the atmosphere much drier at this stage and leave the top ventilator partly open throughout the night. A mulch of moss litter or manure from a spent Mushroom bed spread over the surface of the bed will keep the soil from cracking and be beneficial in other respects.

Melons for successional crop.—Plants showing fruits should have the point pinched out of the leading shoot when within a foot of the top of the trellis, and the lateral shoots stopped at the leaf beyond the fruit. Tie up and regulate the young growth. Pollinate the female flowers at midday with pollen taken from the male flowers. Another method is to remove the petals from the male flowers and place the male in the centre of the female flowers. Do not allow one fruit to swell greatly in advance, but endeavour to obtain a "set" of three or four fruits on a plant at one time. Keep the atmosphere of the house rather dry when the plants are in flower, and ventilate it more freely. Let the atmospheric temperature at night be about 70°, and by day 85°.

THE KITCHEN GARDEN.

By WILLIAM H. HONESS, Gardener to C. COMBE, Esq., Cobham Park, Surrey.

Celery and Celeriac.—Celery plants that have been raised from seeds sown in February, as advised in a former calendar, and intended for the earliest crop, should now be ready for planting out in the permanent quarters that have been prepared for them. Sprinkle the plants liberally with soot, directly they have been put out and copiously watered. The plants of Celeriac raised from a sowing made at the same time as the Celery should likewise be planted out and treated as already described for the Celery. This batch of Celeriac will constitute the main crop.

Brussels Sprouts, Broccoli, and Borecoles should receive timely attention by planting them out as soon as they are ready for moving, particularly if they are still in the seed beds. Many things require attention just now, and these vegetables are therefore apt to be left in the seed beds too long; they consequently get dry at the roots and become drawn up weakly. Such plants are not suited to successfully withstand a severe winter.

Vacant ground.—Various plots of ground which have produced crops of Broccoli and similar vegetables are becoming exhausted. These should be relieved of the old stumps immediately, and prepared for crops of late Peas, Carrots, &c.

Destruction of weeds.—Close attention must constantly be given to all growing and young crops, by keeping them free from weeds and stirring the surface soil with the hoe. In very showery weather it is sometimes a difficult matter to get on the ground, therefore let every convenient opportunity for destroying weeds be utilised.

Runner Beans that have been started into growth in boxes should now be ready for planting out in prepared trenches, planting them at from 9 to 12 inches apart in double rows. As soon as planting is completed, place the sticks in position, as these will both help to protect them from frost, and prevent the risk of injury from winds.

Rhubarb.—Remove all the flower-stems that are showing, because these would weaken the plants if allowed to remain.

Maize.—If seeds have not been sown already, they should be sown at once in drills drawn from 4 to 5 inches deep, and 3 to 4 feet apart from each other. Plants that have been started into growth in pots or boxes, and are now being hardened off, should be planted out at the end of the present month. Maize or "Indian" Corn requires a hot season, but should be afforded occasional drenchings with water.

Rampion seed should be sown at the present time, and again after a fortnight. Make the surface soil fine and level before sowing the seeds. Rampion (*Campanula Rapunculus*) should be more generally cultivated, for both the leaves and roots are useful.

PUBLIC PARKS AND GARDENS.

By W. W. PETTIGREW, Superintendent of the Parks and Open Spaces in the City of Cardiff.

Cycling in parks.—Cyclists are generally regarded as one of the most selfish classes of the community, whose disregard for the comfort and convenience of their fellows is only exceeded by their disinclination to walk where there is the slightest pretext for riding. It would almost appear as if in the eyes of the average cyclist, pedestrians had no rights whatever.

Such being the case, it is not surprising that cyclists have to be carefully regulated in public parks, otherwise they would monopolise every road and footpath in them. In the majority of parks cycling is, very rightly, prohibited altogether; whilst in some it is only permitted during the early hours of the morning, or restricted to well-defined parts of the park.

Excepting in very large parks, where there are broad carriage drives with side walks, it is inadvisable to allow cycling during the whole day. Visitors frequenting parks in the hope of enjoying a quiet walk, or a rest, should not be subjected to the annoyance of having to get quickly out of the way of a cyclist, or run the risk of being knocked down and injured. Once the feeling of security is done away with in a park, one of its greatest charms has been destroyed. Cycling even during early morning hours should only be tolerated on roadways over 20 feet wide; where they are of less width than that cycling should under no circumstances be permitted during any part of the day.

In some towns special cycling tracks are provided in recreation grounds, but unless these are fenced off in such a manner as to prevent children from straying upon them from the adjoining playing ground, they are a continual source of danger. Many years ago a cycling track was laid down in one of the recreation grounds here, but had to be abandoned on account of its being dangerous for children.

Taking everything into consideration, there is no reason why a public parks department should cater for cyclists, as they have abundant scope for their pastime in every highway.

THE HARDY FRUIT GARDEN.

By J. MAYNE, Gardener to LORD CLINTON, Bickton, East Devon.

Pears.—Trees that have set large crops of fruit should be examined and have their fruits thinned where necessary. Remove first those that are badly placed, as well as any showing signs of cracking or deformity. The Pear midge has not been especially destructive this season, and, with perseverance in destroying all fallen fruits, or, better still, picking them off and burning them as soon as they are noticed, this pest can be largely lessened, if not entirely eliminated. Robust trees may require some of their gross-growing shoots pinched to equalise the flow of sap, but defer much summer pruning till a later date.

Plums often set their fruits in such large clusters that it becomes necessary to severely reduce their number. The Czar, Monarch, Coe's Golden Drop, and Victoria are heavy croppers, and usually claim first attention in the matter of thinning. In thinning the clusters of fruits, a pair of Grape scissors will be found useful. Frequently on light, sandy soils, Plum trees on warm walls are badly attacked by red spider early in the summer, and where this happens do not wait until the trees show by their appearance that the pest is present, but ply the garden engine, hose, or syringe two or three evenings each week as a preventive. Keep the roots well supplied with water, and replace the mulching material if it has become exhausted.

Peach and Nectarine trees growing against walls demand almost daily attention in the matters of training, disbudding, thinning of the young fruits, syringing the foliage, and supplying the roots with water. In training the young shoots, great care is required, or their points may become broken. A strand of raffia tied to the fruiting wood at the base, and a second tie to the nearest wire will keep the young shoots in position. Where wires do not exist, a slender twig of privet or a thin piece of lath placed at either end under the old wood will secure the shoots, after the base has been drawn in to the wall with a strand of raffia, and this will be found better than nailing for the present. The removal of surplus shoots at this stage must be done with care, so as not to tear away the bark; they can be best removed with a sharp knife. Complete the final thinning of the fruits in late districts. Hoe and rake off any weeds. Apply a thorough watering if found necessary with water mixed with the drainings from a stable or cowshed, but avoid strong doses of liquid manure. After watering, apply a mulch of straw litter to a depth of about 2 inches. Wash the foliage every evening if convenient, directing the water well underneath the same.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Special Notice to Correspondents.—The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.

Illustrations.—The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but he cannot be responsible for loss or injury.

APPOINTMENTS FOR JUNE.

SATURDAY, JUNE 1—
Soc. Franc d'Hort. de Londres meet.
German Gard. Soc. meet.

TUESDAY, JUNE 4—
Scottish Hort. Assoc. meet.
Nat. Amateur Gard. Assoc. meet.

WEDNESDAY, JUNE 5—
Bath and West. and Southern Counties Sh. at Newport (Mon.) (5 days).

THURSDAY, JUNE 6—Linnean Soc. meet.

MONDAY, JUNE 10—
Unit. Hort. Ben. and Prov. Soc. Com. meet.

TUESDAY, JUNE 11—Roy. Hort. Soc. Com. meet.

WEDNESDAY, JUNE 12—
Roy. Cornwall Sh. at Liskeard (2 days).
Roy. Bot. Soc. Summer Exhib. (3 days).

THURSDAY, JUNE 13—
Colonial Exhib. at R.H.S. Hall, Westminster (2 days).

SATURDAY, JUNE 15—German Gard. Soc. meet.

WEDNESDAY, JUNE 19—York Gala (3 days).

THURSDAY, JUNE 20—Linnean Soc. meet.

MONDAY, JUNE 24—Midsummer Day.

TUESDAY, JUNE 25—
Roy. Hort. Soc. Com. meet.
Brit. Gard. Assoc. Ex. Coun. meet.

WEDNESDAY, JUNE 26—
Colchester Rose Sh.
Richmond Fl. Sh.

THURSDAY, JUNE 27—
Isle of Wight Rose Sh. at Shanklin (provisional).
Canterbury Rose Sh.

FRIDAY, JUNE 28—Roy. Bot. Soc. meet.

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich—58°1'.

ACTUAL TEMPERATURES:—

LONDON.—Wednesday, May 29 (6 P.M.): Max. 43°; Min. 56°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—Thursday, May 30 (10 A.M.): Bar. 30°1'; Temp., 55°; Weather—Cloudy.

PROVINCES.—Wednesday, May 29 (6 P.M.): Max. 58°, Ireland, S.W.; Min. 44°, Scotland N.

SALES FOR THE ENSUING WEEK.

WEDNESDAY—
Bedding Plants, Bulbs, Lilies, Palms, Bays, Japanese Dwarf Trees, &c., at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.

The Temple Show.

The Royal Horticultural Society's twentieth exhibition in the famous gardens of the Inner Temple is still open as these pages go to press. We are compelled, therefore, by exigencies of time and space to write of it almost upon first sight, and at such close quarters, if we may so express it, that it is difficult, perhaps impossible, to form a correct judgment as to its exact place in comparison with previous shows held on the same site. The Temple Show has become such an important institution, so comprehensive as an exhibition of British horticulture, it is hardly to be expected that each event should be greater or better than its predecessor. Rather is it a correct illustration of the changes that occur in the estimation entertained by the public for different types of plants. Except for such fluctuations, and

for the introduction of new species and home-raised hybrids, what should prevent every Temple Show being an exact reproduction of previous displays? The season of the year is the same (the show is only one day later than last year), similar plants are therefore in flower, and species that were out of season then are also out of season now. The conditions being so much the same, we are thus enabled to see from year to year what effect is produced by the vagaries of fashion, the enterprise of plant collectors, the skill of plant-breeders, and the care of the cultivators. In its testimony to high cultivation the present show is ahead of all its predecessors, and it is a most effective advertisement of the increased ability and skill of the practical gardeners in this country. Foreign visitors are greatly impressed by this feature

FIG. 146.—*VIOLA GRACILIS*: FLOWERS DEEP PURPLE.

of the show, and if visitors nearer home are not so quick to realise the high type of culture exhibited, it is because the progress is gradual, and therefore less perceptible to those who visit exhibitions at frequent intervals.

As showing how the introduction of new plants affects such shows, it is only necessary to refer to the many valuable species of trees, shrubs, and other plants which Messrs. James Veitch & Sons have introduced from China. Not only may such plants be seen in this firm's exhibits, but they are included in many others. The remarkable *Primula Cockburniana*, already illustrated in these columns, having vivid, orange-coloured flowers, but possessing a weak habit of

growth, which is not such as to make it a good garden plant, has been crossed with the strong-habited *P. pulverulenta*, and in the Temple Show of 1907 the first seedlings from this cross are shown by Messrs. Veitch under the name of *P. x Unique*. The seedlings appear to be almost perfectly intermediate between the parents, and it is not too much to say that at future Temple Shows visitors may expect to see groups of orange-coloured *Primulas* of a good habit and that are easy of cultivation. The vivid colouring of *P. Cockburniana* has suffered a little from the cross, but, having obtained the habit which was desired, the plant-breeder may be trusted to get back the original clear and vivid colour.

The effects of cross-breeding are more conspicuously evident in the Orchids than any other class of plants at the present day, and it is a fact that there has never been a better collection of Orchids exhibited at a Temple Show than that at present on view. In this connection we are sure everyone will congratulate Major Holford on the magnificent collection for which he has been awarded the Veitchian Cup, which this year was offered for the best exhibit of any kind contributed by an amateur. The collections of Orchids from Mr. Colman, Messrs. Sanders & Sons, Charlesworth & Co., Low & Co., Bull & Sons, are full of extraordinary hybrids obtained by purposeful cross-breeding. In Carnations, Roses, and Begonias great advancement may also be noticed, for in all these respects the exhibits are of higher quality and greater variety than formerly.

The excellent groups of *Hippeastrums* shown by Major Holford and Messrs. Ker & Sons afford further instances of advancement, and the same might be said of the *Cinerarias* from Messrs. Sutton & Sons, *Gloxinias* from this firm and Messrs. Peed, Cannas and other florists' flowers from Messrs. Cannell & Sons, *Rhododendrons* from Messrs. Waterer & Sons, R. & G. Cuthbert, and Mr. Chas. Turner, and others.

Quite another description is the little *Viola*, reproduced at fig. 146 from a sketch made by Mr. Worthington Smith during the press of the opening day. It has bright, rich purple flowers, and Messrs. Wallace inform us that, on a rockery, the plant is exceedingly effective. It is remarkable for its extremely narrow leaves, which are very different in shape to the more oval foliage of the cultivated *Violas*. The species is not a perfectly new one, but it is rare and hardy, and may be recommended to cultivators who desire that their plants should possess distinct characteristics. The popular appreciation for hardy plants is well reflected in the Temple Show, and they are staged in numerous and comprehensive collections. What an amount of labour and expense is involved in the exhibition of such a rockwork as Messrs. Cutbush & Son have arranged and planted out of doors!

Fruit trees, laden with luscious fruits, and vegetables from such famous gardens as Aldenham and Welbeck, testify to the fact that horticultural skill is not wholly devoted to the production of ornamental plants and flowers, but also to the cultivation of crops of the greatest economic value.

NEW POLYANTHA ROSE "AENNCHEN MÜLLER," WITH REVOLUTE PETALS ;
COLOUR OF FLOWERS, BRIGHT PINK.

A full report of the exhibition is printed on other pages, and it therefore only remains for us to thank the Society for the service it renders to horticulture by the holding of such exhibitions, and to congratulate the officials on another unqualified success. It is reported that the receipts on the first day again established a record!

The Orphan Fund.

It is a matter for congratulation that, as the result of the Festival dinner which took place last week, the Royal Gardeners' Orphan Fund has benefited to the extent of £1,000. We have in these columns so often urged the claims of the Fund upon the generosity of the horticultural public, it is a pleasure to know that in the present year its income is likely to be equal, or more than equal, to any previous record. All who take a proper interest in the welfare of gardeners' orphan children, left without any provision for their needs, will feel grateful to the Lord Mayor (Alderman Sir William Treloar), Sir Albert Rollit, and other gentlemen for the help they afforded on this occasion.

Mr. Edward Sherwood, as Treasurer, again referred to the disproportion existing between the amount raised by means of the annual festival and that obtained from regular subscriptions. Whilst the festival is responsible for £1,000, the whole of the annual subscriptions amount only to about £300. This state of things is not what it should be. The list of annual subscriptions could easily be doubled if gardeners could be brought to thoroughly realise their responsibilities. A subscription of five shillings each year is certainly within the means of every gardener holding a position of responsibility, yet it appears that only about one in ten contribute this amount.

It is in every way desirable that the efforts of the Executive Committee to raise an increased amount by subscriptions from gardeners themselves, should be successful.

In the meantime we are glad to know that the invested funds amount to upwards of £11,000. This may be regarded as sufficient at the present time, but it is important that the amount should be increased if the number of orphans dependent upon the Fund become more numerous.

The Proceedings at Upsala.

In our last issue we referred to the bi-centenary of the birth of Linnæus, and to the general desire of botanists in every country to fittingly celebrate the occasion. We are now in a position to publish some particulars of the proceedings at Upsala and Lund in honour of the great Swedish botanist.

The celebrations commenced at Lund, on Tuesday, May 21. Only a few strangers were present, but they received a cordial welcome from the Rector of the University, Dr. Ribbing. After examining the portraits and relics of Linné exhibited by Prof. Nerdstedt, a grandson of Linné's niece, the Rector entertained at lunch about 50 guests. A special train took the guests and some 300 students to Rashult, where Linné was born. An extraordinary scene was presented there. Three thousand people crowded the woody hill-side on which the house of Linné's father stands; flags were flying, the footpath was lined with bright little children in gay dresses, and the students, singing as they passed along the

path, were followed by the visitors. It was an unprecedented sight for quiet Rashult. Dr. Simmons, of Lund, botanist, delivered an oration on the life and work of Linné. Thereafter, a visit was paid to the church, of which the father of Linné was pastor.

Most of the foreign visitors arrived at Upsala on the morning of the 23rd ult., and were received at the station by the students carrying their banners. It was a remarkable scene. After singing a welcome, the students marched in a compact procession to the University. There was a small sprinkling of lady students, who doffed their college caps and shouted their hurrahs with as much enthusiasm as the rest. At midday the students filed into the Aula of the University, and were followed by the delegates. The galleries were already packed with ladies when the Prince Regent and members of his family entered. Every corner was filled and the splendid semi-circular Aula was a grand sight. The Rector, Dr. Schück, delivered an able address on Linné's life and an elaborate exposition of his labours. Thereafter, the delegates were received in the alphabetical order of their countries, one man for each country delivering a short congratulation. Sir Archibald Geikie's was, perhaps, the shortest address, but it was very appropriate, and was received with applause. The various addresses and medals were handed in as the delegates passed the Rector. It was a memorable assembly to all present. The foreign delegates passed into a smaller room, and were personally received by the Prince Regent, and at the close the Prince decorated several of them, among whom were Prof. Poulton and Mr. B. Daydon Jackson from England. In the evening the Rector entertained the visitors at dinner, at which only three toasts were proposed, one being the Linnean Society of London, to which Mr. W. Carruthers, F.R.S., as the representative of the society, replied.

Friday morning was ushered in with a salute of 21 guns from the castle. The event of the day was the promotion of many Swedes and foreigners to degrees in the faculties of theology, law, medicine, and philosophy. This took place in the ancient and beautiful Cathedral of Upsala, where Linné is buried, and where, in a side chapel, his monument, with the Serpel portrait, is erected. The members of the public who had access to the interior filled every place allotted to them. The students met in the University and marched in procession to the cathedral, followed by the foreign delegates. As soon as the Prince Regent and his party had entered, the ceremony began with religious exercises, led by the Archbishop. Then followed some charming music, which was renewed at intervals throughout the meeting. As each recipient had the hat, or, in cases of the faculty of his philosophy, the laurel wreath, placed on his head, a gun was fired from the castle. The following delegates from England were created doctors of philosophy:—Sir Arch. Geikie, Prof. F. Darwin, Wm. Carruthers, and B. Daydon Jackson. After the ceremony was over, the students and doctors returned in procession to the University. The students, with their banners and their white caps, presented a fine spectacle as they marched up the winding path leading to the University. They arranged

themselves in front of the grand entrance, the graduates being grouped on the steps. They again sang several pieces with beauty and energy. Such a scene could not be equalled in any University elsewhere. The University gave a dinner in the Aula, at which 400 guests were present, the Prince Regent and his party being in the place of honour.

The celebration of the Royal Swedish Academy of Sciences, of which Linné was a founder and its first president, was held on Saturday, the 25th ult. The proceedings took place in a large concert hall, which was crowded. The speaking and the music were better heard than in the large Aula of Upsala University. A large orchestra with a fine choir supported by some well-known singers, rendered admirably the music composed for the occasion. Count K. A. H. Mörner delivered an eloquent oration on Linné, narrating the events of his life and dwelling on the value of his works. The newly-struck Linnean medal of the Academy founded at this bi-centenary celebration was to be presented to Sir Joseph Dalton Hooker, whose labours in botany Count Mörner shortly and clearly stated. Amid the cheers of the audience he handed the medal to the British Ambassador at Stockholm. Great was the delight of the British delegates, who were more in number than those of any other country, and many were the congratulations received by them for the honour so well deserved by England's distinguished botanist. The honour, Sir A. Geikie said, would be a valued birthday gift to Sir Joseph, who will celebrate his 90th birthday in the course of a few weeks. Bronze copies of the medal were given to some of the delegates. The representatives of the different countries were received in the same order as at Upsala, and a short statement was made by one member from each country. A dinner followed, and an afternoon tea at the invitation of the Prince Regent on the following day completed the celebrations. No one who witnessed the events will forget them. The weather was remarkably good, and everything was done to make the Linné festivals at Lund, Rashult, Upsala, Hamm, Hammarby, and Stockholm successful.

It may be added that the Linnean Society of London will celebrate the event by a reception and soirée on June 7. The principal exhibits will be of objects associated with or belonging to Linnæus, such as letters, manuscripts, and objects of natural history.

OUR SUPPLEMENTARY ILLUSTRATION represents the beautiful new *Polyantha* Rose Aennchen Müller, as sketched by Mr. WORTHINGTON SMITH from specimens exhibited by Messrs. WM. PAUL & SON, at the meeting of the Royal Horticultural Society, on April 30 last. The variety is of German origin, as is indicated by the name. The flowers are of a rich shade of coral-pink colour, and are produced in clusters in extraordinary profusion. The individual flowers measure about 1 inch in diameter, and the petals are rolled backwards which gives the whole flower a very distinct and pleasing character. The variety continues in bloom almost uninterruptedly from June until late autumn. The plants attain to a height of from 1½ to 2 feet, and in their dwarf habit of growth they are particularly suited for planting in masses or in groups. That the variety is also well adapted for forcing and for pot-culture was evidenced by the handsome plants in pots shown by Messrs. PAUL at the meeting already mentioned.

LINNEAN SOCIETY.—A meeting will be held on Thursday next, June 6, at 8 p.m., when the following papers will be read:—(1) Prof. A. DENDY, F.L.S., and Mr. E. HINDLE, "Contributions to our Knowledge of the New Zealand Holothurians;" (2) Prof. W. A. HASWELL, "Observations on Australasian Polyclads;" (3) Mr. C. TATE REGAN, "Report on the Marine Fishes, collected by Mr. J. Stanley Gardiner in the Indian Ocean;" (4) M. FOSLIE, "The Lithothamnium of the 'Sealark' Expedition;" (5) Prof. L. G. NEUMANN, "Notes sur les Ixodidae recueillis dans les îles de l'Océan Indien, par Mr. J. Stanley Gardiner." Exhibitions:—Mr. G. CLARIDGE DRUCE, F.L.S., *Orobancha Ritro*, and some new varieties of plants from the Channel Islands.

FLOWERS IN SEASON.—From Messrs. JAMES VEITCH & SONS, LTD., Royal Exotic Nursery, Chelsea, we have received flowers of the dark form of *Magnolia Soulangeana* and known as *nigra*; a spray of *Exochorda grandiflora*, a handsome, hardy flowering shrub, having racemes of large white flowers; the rose-coloured form of *Clematis montana*, named *rubens*; and *Trochodendron aralioides*, a shrub with leathery, ovate, acuminate leaves on long petioles, and having a curious terminal inflorescence consisting of a raceme of apetalous flowers, with disc-like gynæcium surrounded by an indefinite number of stamens: the whole of a greenish-yellow colour. Messrs. VEITCH also sent a number of named Lilacs, including *Souvenir de L. Spath* (purple), *President Viger* (double lilac), *Emile Lemoine* (soft heliotrope), *President Grevy* (lavender-blue), *Mad. Casimir Perier* (white), *Mad. Lemoine* (double white), *Charles Joly* (purple), *Marie Legraye* (white), *Mdlle. Mélide Laurent* (lilac), &c.

Mr. S. WYNDHAM FITZHERBERT sends a spray of *Semele* (*Ruscus*) *androgyna* from the open in Devon, with numerous small flowers upon the margins of the phylloclades. Our correspondent writes: "There are good specimens at Penjerick and at Rosehill, Falmouth, which occasionally bear fruit. My plant has not as yet fruited. A wall covered with this climber is a beautiful and uncommon sight, the glistening green of the great drooping leaves being very effective and pleasing. Small plants require two or three years to become established, and the younger is the plant the earlier it starts into growth. For the first two years my specimen commenced to grow in November, and by December had shoots 4 feet in height. Now that it has increased in size it does not start into growth until April."

Mr. D. STORRIE, of Messrs. STORRIE & STORRIE, Dundee, obligingly sends us examples of hybrid forms of Cowslips, Polyanthus and Primroses in which a great advance is seen, and which promise to be choice acquisitions for the garden. Mr. STORRIE writes: "I hope to exhibit at the Temple Show a small group comprising Cowslips, Cowslip $\times$ Polyanthus, Primrose, Primrose $\times$ Polyanthus, hybrid Polyanthus, Polyanthus $\times$ Primrose, and one solitary plant of Cowslip $\times$ Primrose—the first I have met with as a natural cross. In the meantime, I send you by same post three bunches of blooms representing the three main types, and in my exhibit the evolving or intermediate stages will be shown, as well as the devolving stage from Polyanthus back to Primrose. It is a notable fact that in the Cowslip $\times$ Polyanthus there are no 'whites,' and a white Cowslip is as yet a thing to dream of."

RESEARCH STATION AT WISLEY.—The laboratory and experimental research station in the Royal Horticultural Society's Gardens at Wisley will be formally opened, on July 19 next, by the Right Hon. Lord AVEBURY, P.C., F.R.S., &c.

COVENT GARDEN "EMPTIES."—For some time past there has been an agitation by dealers against payment for boxes and baskets containing fruit and flowers for sale, the receptacles being non-returnable. This practice is the most common in respect to the imports from France. Previously, the crates, baskets, &c., were charged for at the time of sale, but the money was refunded when they were returned empty. The buyers have considered the enforced purchase of the receptacles to be an imposition, especially as the charges for the same were considered

the Apple cases from Australia and Tasmania, or the barrels from America. Some English growers impose a charge for baskets, but in such cases full allowance is made for them when they are returned as empties.

SALE OF THE "CLARE LAWN" ORCHIDS.—The sale of the Orchids that belonged to the late Sir FREDERICK WIGAN took place at Messrs. PROTHEROE & MORRIS' Rooms on May 22, 23, and 24, and was highly successful, the total sum realised amounting to about £4,600. From

FIG. 147.—AN IMPROVED VARIETY OF PRIMULA SIBERICA EXHIBITED BY MESSRS. JAMES VEITCH AND SONS AT THE TEMPLE SHOW.

(It has larger flowers than the type: colour rose-pink.)

to be in excess of their actual cost. They, therefore, decided to refrain from dealing with any broker who charged for the packages, and at a meeting of brokers and others held on the 29th ult. it was decided to abolish the charges. This decision will settle the matter, and save much trouble. It will also put the French produce on the same footing as goods received from other foreign countries. No charges have ever been made for

the sale of the first lot to the last there was keen competition, especially for the best varieties, including the white *Cattleyas* and the remarkable hybrids. The most notable feature in the sale was the increase in the price of good varieties of *Miltonia vexillaria*, three plants of the very fine *M. v.* "Memoria G. D. Owen" realising 500 guineas, 420 guineas, and 390 guineas respectively. *Miltonia vexillaria alba* fetched

38 guineas, and other good forms sold for proportionately good prices. *Cattleya labiata alba* went for 66 guineas; *C. labiata Cooksoniae* 72 guineas; *C. Mossiae The Queen*, 21 guineas; *C. Mossiae Wageneri*, 28 guineas; *C. Schroderae alba*, 27 guineas; and other white *Cattleyas* fetched good prices. A fine type of *Sophr. Cattleya Doris* realised 40 guineas, and for a smaller plant 13 guineas was paid. "Botanical" and rare species also found favour among purchasers, a good specimen of *Cymbidium Devonianum* selling for 32 guineas, *Megacelinum falcatum* 6½ guineas, *Bulbophyllum virescens* 19 guineas, *B. Ericssonii* 6 guineas, *B. grandiflora*

mission of C. H. RAFTER, Esq., Chief Constable), will perform between 8 o'clock and 6.30 p.m. each day.

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

SECRET COMMISSION.—The heavy sentences imposed by Mr. Justice Jelf in the case of the West Ham Guardians who accepted secret commissions from tradesmen, seem to furnish a useful guide to the attitude which it is the

the offers of secret commission made by other firms he found it impossible to secure orders unless he in his turn were equally ready to give such commission. It appears to me that the lessons to be learned from this case are threefold: (1) "Murder will out," and however secret these transactions may be, and however much the servant and tradesman may trust each other not to disclose these illicit transactions, there is always serious danger to be faced by those who may seek to evade the provisions of the Prevention of Corruption Act. (2) Where a conviction is secured the judges are apparently determined to award severe terms of imprisonment. (3) Honesty is, as it has always been, the best policy in the long run. I think the trade should

FIG. 148.—BRASSO-CATTELEYA MRS. J. LEEMANN VAR. RAJAH, SKETCHED AT THE TEMPLE SHOW IN MESSRS. SANDER AND SONS' GROUP: COLOUR OF FLOWER YELLOW, WITH SHADING OF ROSE.

£3. *Cypripedium bellatulum album*, of which there were several small plants, sold well, and the rose-blotched *C. bellatulum* "Princess Clementine" went for 44 guineas. The sale was unreserved, and as the collection was very varied, and represented all classes, the results show how valuable the best Orchids really are.

FLOWER SHOWS AT BIRMINGHAM.—The first of the two flower shows already announced for holding in the Botanical Gardens, Edgbaston, will be held on Wednesday, June 12, and the second on Wednesday, July 3. Intending exhibitors are invited to make early application for space so that the necessary arrangements may be made. The exhibition will open at 12.30 and close at 7 p.m. The City of Birmingham Police Band (by kind per-

intention of his Majesty's judges to take in connection with the giving or receiving of secret commissions. It is true that the recent prosecution was instituted under the Public Bodies Corrupt Practices Act, 1899 (in addition to charges of conspiracy to defraud at common law), but this Act and the Prevention of Corruption Act appear to be framed on similar lines; in fact, much of the wording of the latter Act is evidently founded on the phraseology of the former Act. Furthermore, the penalties of fine and imprisonment under both statutes are the same, that is to say, in each case there is liability to imprisonment for a term of two years, or £500 fine, or both. It seems instructive to remember that in the West Ham case the public represented the employer, the guardians represented the servants or agents entrusted with the giving of orders, and the tradesman who gave the commission put forward the excuse that owing to

feel indebted to the Horticultural Trades' Association for the firm stand which they have already taken in dealing with this subject. There can be no doubt that the drastic sentences in the cases mentioned above have already made a deep impression on the minds of traders of all classes throughout the country, and the efforts of the various trade associations in endeavouring to stamp out the practice of giving these commissions are likely to be redoubled. I enclose my name and address. *Anti-Corruption.*

FROST AT WHITSUNTIDE.—A frost on the morning of Whitsunday blackened early Potatoes and Kidney Beans in this district, and I hear that frost also caused much damage to Potatoes in Cornwall on the same date. The old saying that one cannot safely start summer-bedding until after May 20 has proved only too true this season. *J. Mayne, Bickton, Devon.*

Royal Horticultural Society.

THE TEMPLE SHOW.

May 28, 29 and 30.

THE greatest floral event of the year, the Temple Flower Show, took place on the above dates, and another success is to be added to the list of these remarkable exhibitions. Here, in a space of less than an acre, were collected the very finest products of our gardens and nurseries, and, one may say, in the world, for some continental friends send of their best. Although the general plan is each year necessarily similar, some new features were seen, and the exhibits in the open garden formed a not inconsiderable portion of the exhibition. The Orchids were more beautiful than ever, and especially in the direction of hybrids there was a great advance. Roses were, perhaps, not so fine as on some former occasions, and fashion changes in flowers as in other things, which accounts, undoubtedly, for the exhibits of Clematis, Caladiums, and a few other subjects being of less importance than in some of the earlier exhibitions. But advance is seen in other directions, and magnificent were the Carnations, tuberous-rooting Begonias, pillar Roses, Cannas, and many other subjects. The weather on the opening day was dull, and the wind was keen, but, although rain threatened, it fortunately held off. The attendance of the visitors must have been a record, for at times the tents were packed, and one could only move with "the crowd." This is not to be wondered at when one remembers that the society now consists of more than 10,000 Fellows, each of whom is entitled to be present with friends.

The arrangements of the show were perfect, and the secretaries, the superintendent (Mr. S. T. Wright), Mr. Frank Reader, and the other officials are to be congratulated upon the excellent way in which the whole was managed.

Orchid Committee.

Present: Harry J. Veitch, Esq. (in the chair), and Messrs. Jas. O'Brien (Hon. Sec.), De B. Crawshay, H. J. Chapman, W. Boxall, F. J. Thorne, A. Dye, F. Sander, H. Ballantine, G. F. Moore, W. H. White, J. Colman, W. A. Bilney, W. P. Bound, W. Cobb, F. M. Ogilvie, J. W. Odell, W. Bolton, W. Thompson, H. T. Pitt, C. J. Lucas, H. A. Tracy, W. H. Young, J. Wilson Potter, Francis Wellesley, H. G. Alexander, R. Thwaites, T. W. Bond, E. Ashworth, and F. J. Hanbury.

Major G. L. HOLFORD, C.I.E., C.V.O., Westonbirt, Tetbury (gr. Mr. H. G. Alexander), had an extraordinary group of rare, handsome, and splendidly-grown plants arranged in the most effective manner and occupying 200 square feet, and which justly secured the Veitchian Cup as the highest award made at this show. The different types of flowers were admirably arranged so as to show to the best advantage, each set being made a special feature. Of *Odontoglossum crispum* of the finest type some 50 specimens were used in the group, each bearing fine spikes of 12 to 20 flowers. *O. crispum* Hilda was a fine spotted variety, and *O. c. Osra*, Juno and Egret were handsome forms. The stately *O. Wilckeanum* Rex bore 18 flowers, and one specimen of *O. Pescatorei* had a spike of 70 blooms. Of fine forms of *Miltonia vexillaria* there were 130 spikes, the largest specimen having 18 spikes, with an aggregate of about 100 flowers. Among the best were the richly coloured *M. vexillaria* Empress Augusta Victoria and *M. v. Cobbiana*, the white *M. v. virginale*, the showy *M. v. marmorata*. Of hybrids and allies there were *M. Bleuana nobilior* and *M. Roezlii album*. The fine forms of *Cattleya Mossiae* provided nearly 150 blooms, and included the white varie-

ties *Reineckiana* Westonbirt variety, *Reineckiana superba*, and *Wagneri*. The forms of *Lælia purpurata* also were much in evidence, their large rose or white petalled flowers, with rich crimson or purple labellums, being very effective. Remarkable for the bright veining on the petals were the varieties *Fastuosa*, *Annie Louise*, and *Backhousiana*, and for the clear white of its petals the variety *alba*. Westonbirt is famous for its hybrid Orchids, and the display in the group was well worthy of it. One of the most beautiful and charming in colour was *Lælia-Cattleya* Golden Glory [see fig. 151], with a wealth of light crimson-lipped golden-yellow flowers. L.-C. Canhamiana Rex represented the largest dark variety, the variety "Lady Wigan" being the prettiest light form; the new Westonbirt seedling L.-C. Ganymede well displayed its peculiar colours, and good L.-C. Fascinator and other fine forms were noted. Of hybrid *Cattleyas* one of the most attractive was the clear white *C. Dusseldorfei* var. *Undine*, for which Major Holford had already received a First-class Certificate. *C. Empress Frederick* and other

p. 322; the handsome *O. crispum xanthotes*, White's variety, these two being the only plants out of the fine collection which Messrs. Sander entered to go before the Orchid Committee, and both secured First-class Certificates. Among the other *Odontoglossums* the best appeared to be *O. crispum* Sanderæ, of a peculiar red colour, with white margin and intersecting lines; *O. crispum* "Beauty," a blending of the blotched and the punctatissimum class; *O. crispum* "Prince of the Asturias" (see fig. 150), and *O. crispum* "Lord Cromer" (see fig. 149), two very handsome and finely blotched forms obtained by crossing a good blotched variety with *O. crispum* Graireanum, the orange-tinted purple of the latter showing in the progeny. Of hybrids *O. ardentissimum* "The Earl" had grand flowers blotched with purple; *O. ardentissimum* Kalistion was a distinct and good form; *O. Prince Albert*, a new type of hybrid with reddish flowers, the tips and margins only being white; *O. Fascinator*, broad and heavily blotched with dark purple; *O. mirum magnificum*, a great advance in its class; *O. crispo-Harryanum*

FIG. 149.—ODONTOGLOSSUM CRISPUM "LORD CROMER," FROM MESSRS. F. SANDER AND SONS' EXHIBIT.

fine hybrids and species were also represented in splendid condition, and among the *Brasso-Cattleyas* were B.-C. Digbyano-Schröderæ, Westonbirt variety, a grand blush-white flower with large fringed labellum, and various other *Brasso-Cattleyas* and *Brasso-Lælias*, including the new, bronzy-tinted B.-L. Gipsy. Of *Cypripediums* noted were a fine specimen of *C. Lawrenceanum* and its albino *Hyeaenum*, *C. Maudiae magnificum*, *C. callosum* Sanderæ, good *C. niveum*, &c. Other fine effects were made by the arching sprays of large white flowers on *Phalaenopsis Rimestadtiana*, the rose tints of *Vanda teres*, the scarlet of *Epidendrum radicans*, and the graceful sprays of *Thunia Marshalliana*, T. Veitchiana, *Dendrobium Dalhousianum luteum*, &c.

Messrs. SANDER & SONS, St. Albans, had a magnificent group, specially rich in fine *Odontoglossums*, among which were the unique *O. crispum* "Solum," a marvellous white variety with the whole labellum of a rich, dark ruby-crimson colour, and which was well illustrated in the *Gardeners' Chronicle* for May 27, 1905,

Brugense, large and finely marked; and *O. Pescatorei* "Princess," a clear white variety of fine shape; *O. Wilckeanum* Miss Louisa Fowler bore two spikes of noble primrose-yellow coloured flowers of great size and finely blotched with chestnut-brown; *O. splendidissimum* (*Pescatorei* x *ardentissimum*) was very handsome. Two plants of the rare *Odontonia Lairesseæ*, with branched spikes of rose-coloured and white flowers, were noted; also among the hybrids of *Brassavola Digbyana* the very beautiful *Brasso-Cattleya* Mrs. J. Leemann, variety "Rajah" (see fig. 148), obtained by using Messrs. Sander's *C. aurea chrysotoxa*, was very handsome. The flower is of bright yellow in the centre, shading to chrome-yellow, the fringe of the lip and sides of the petals being exquisitely flecked with light rose. Among the *Cattleyas*, of which there were many choice white forms, was a noble mass of *C. Mossiae*, with over 100 flowers of fine quality; some splendid forms of *C. Mendelii*; a very fine series of *Lælio-Cattleyas*, L.-C. Canhamiana Rex, which was shown in several good examples,

being very showy, and *L.-C. Canhamiana alba*. *Miltonia vexillaria* included the finely coloured *M. v. Empress Augusta Victoria*, the scarlet *Renanthera Imschootiana*, and many rare species were shown, including a noble plant of *Bulbophyllum Ericsoni*, with its large and quaint umbel of greenish-yellow flowers blotched with purple, and arranged like the cup of a Chinese pagoda.

Messrs. WILLIAM BULL & SONS, King's Road, Chelsea, had the next group, which was made up principally of *Odontoglossums*, *Cattleyas*, and *Lælias*. Among the *Odontoglossums* *O. crispum* Florence and *O. c. Doris* were of the blotched class; *O. ardentissimum* Sunset, *O. perculum*, *O. amabile*, and *O. excellens* were good hybrids. *Cattleya Mendelii* Countess and Princess of Wales were fine white-petalled varieties; *C. Mossiæ* Princess of Wales, *Lælia purpurata* Prince of Wales, *L. p. illustris*, and *L. p. The Queen*, excellent varieties.

Messrs. HUGH LOW & CO., Bush Hill Park, Enfield, completed this side of the stage with an extensive group, in which the forms of *Cattleya Mossiæ* were good throughout, and included several white varieties, the *C. Mossiæ alba* being purest; *C. M. Leonora* had a clear orange disc. *C. M. Mrs. C. H. Feiling*, which had previously secured an Award, is a richly coloured form, and the varieties of *C. Mendelii* of Messrs. Low's importation showed the strain to the best advantage. At one end was a batch of interesting species comprising *Physosiphon Loddigesii*, *Epidendrum atropurpureum*, *E. aurantiacum*, *Cirrhopetalum picturatum*, *Oncidium cucullatum*, *Sophranitis grandiflora*, *Odontoglossum blandum*, &c. Two specially fine plants in the group were comprised in a dark coloured *Lælio-Cattleya Dominiana* and the white-petalled *Lælia purpurata bella*.

On the other side of the table JEREMIAH COLMAN, Esq., Gattton Park, Reigate (gr. Mr. W. P. Bound), had a very fine group excellently well arranged, the end being well filled by a number of plants of the fine orange-coloured *Epidendrum Boundii* and the new red *Epidendrum Gattton Glory*, excellent "decorative" plants. In the main group was a selection of splendidly grown *Odontoglossums*, the pretty blotched *O. crispum* "Mary Colman," with three finely developed spikes, obtaining for Mr. Bound a Cultural Commendation; and the handsomely spotted *O. crispum* Richard Causton. The centre was of white *Cattleyas*, and at the back were fine plants of *Cymbidium Lowianum*, with one fine form of *C. L. concolor*, and a good specimen of *C. Lowio-eburneum*, "Gatton Park variety." On each side were batches of *Lælio-Cattleyas*, *Cattleya Mendelii*, and *C. Mossiæ*, among the latter being the very distinct variety "Jeremiah Colman," which secured an Award of Merit last year. The scarlet *Renanthera Imschootiana*, *Spathoglottis aurea*, "Gatton Park variety," patches of *Cypripedium niveum* and *C. concolor*, *C. Lawrenceanum* Hyeann, *Bulbophyllum Lobbii* and its variety colossus, and many other handsome species and varieties, were also arranged in the group.

Messrs. CHARLESWORTH & CO., Heaton, Bradford, came next with a magnificent group too full of extraordinary plants to admit of reference to a tithe of those deserving notice. The *Odontoglossums* were magnificent, and Messrs. Charlesworth's home-raised, blotched *crispums* yield their first fruits in five splendid varieties, perhaps the best of which is *O. crispum* heatonense, a grandly blotched flower of fine shape, the greater part of its surface blotched with reddish-purple, with only a few intersecting white lines and a white margin. Another fine hybrid was *O. Phoebe magnificum* (*cirrosum* x *crispum* *Luciana* [see fig. 151], a great improvement on the original and a charming flower of novel colour. The ground colour is white, with a slight rose shade and the spotting of a dark reddish-purple colour, the crest of the lip being yellow. In the group were many white *Cattleyas*, a fine lot of *Lælio-Cattleya Fascinator* and other *Lælio-Cattleyas*, some rare *Cypripediums*, including the unique *C. bellatulum* Princess Clementine, large, cream-white, with soft rose-pink spotting; *Brasso-Cattleya Queen Alexandra*, a good white variety; *Cattleya Mendelii* Queen of Spain, *C. M. Princess Thyra*, a pure white with magenta lip; and *C. M. Fushimi*, a remarkable form. *Lælio-Cattleya Canhamiana* "Marguerite" is a

white form with marbling of rose on the petals and lip; the pretty scarlet *Odontodia Vuylstekeæ*, and a showy selection of other hybrids. The selection of *Miltonia vexillaria* were excellent, and among them was a very pure white variety.

H. S. GOODSON, Esq., Fairlawn, Putney (gr. Mr. G. Day), staged a pretty group, made up of showy *Cattleyas*, including a fine *C. Schöderæ* alba and some exceptionally good *C. Mendelii* and white *C. Mossiæ*, a grandly flowered *Renanthera Imschootiana* with two spikes, a selection of *Odontoglossums*, including a few blotched *O. crispum*, good *Miltonia vexillaria*, *M. Phalaenopsis*, &c., the front row being of scarlet *Masdevallias* and Maidenhair Ferns.

Messrs. CYPHER & SONS, Cheltenham, continued with an elegant group, in which the principal feature was made by numerous specimens of splendidly grown *Miltonia vexillaria*, varying from the large, bright rose-coloured type to the white-lipped class of the *M. vexillaria leucoglossa* section and the wholly white *M. vexillaria alba*. Among the best were *M. v. Cobbiana*, *M. v. virginale*, *M. v. gigantea*, and *M. v. Empress Augusta Victoria*. At the back was a very fine set of *Lælia purpurata* of the very best type. There were also *Dendrobium Wardianum* album, *D. Dalhousianum* luteum, a good *Cypripedium* "Miss Louisa Fowler," a very pretty and distinct cross between *C. Chamberlainianum* and *C. Godefroyæ*, and a singular form of the latter with the spotting of *C. bellatulum*.

In the long tent, Messrs. LINDEN, Brussels, showed a selection of varieties of *Odontoglossum*

FIG. 150.—*ODONTOGLOSSUM CRISPUM* "PRINCE OF ASTURIAS," EXHIBITED BY MESSRS. F. SANDER AND SONS, AT THE TEMPLE SHOW.

crispum, including one plant of their new, heavily-blotched seedling *O. crispum* "Reine d'Angleterre," well worthy to rank with the very best of the seedling forms by reason of its rich claret-red blotching. Messrs. LINDEN also showed good *Cochlidia Noezliana*, and a yellow form of this species.

J. RUTHERFORD, Esq., Beardwood, Burnley (gr. Mr. Lupton), showed a selection of white *Cattleyas*, including *C. Mossiæ* Rappartiana and *C. M. Reineckiana*.

FRANCIS WELLESLEY, Esq., Westfield, Woking (gr. Mr. Hopkins), sent *Cattleya Mossiæ* Miss Mary Knollys, a large pure-white flower of fine substance, the crimped and broad labellum having crimson-purple markings in front of the orange-coloured disc, behind which run some purple lines to the base.

Mr. JOHN ROBSON, Altrincham, staged a small group, in which were some very fine *Odontoglossums*, for the best of which see Awards. The best of the others were the finely blotched *O. crispum* "Karthausii," *O. c.* "Empress Frederick," *O. c.* "Dora," *O. c.* Moortebeekense, *O. c.* "Madouxianum," and *O. "Lambeauianum."*

M. CHAS. VUYLSTEKE, Loochristi, Ghent, showed *Odontoglossum crispum* "Fabiola," a showily-blotched seedling form, and three others (see Awards).

Mr. R. ROBINSON, Roath Park, Cardiff, sent an inflorescence of a singular, constant abnormal form of *Dendrobium thysiflorum* near to *D. t. Galliceanum*.

R. ASHWORTH, Esq., Newchurch, Manchester (gr. Mr. Pidaley), staged a small selection of spotted forms of *Odontoglossum crispum*, &c.

Messrs. ARMSTRONG & BROWN, Tunbridge Wells, arranged a very bright and effective group of finely grown plants, comprising a selection of *Odontoglossums*, *Cattleya Mossiæ*, *Lælia purpurata*, &c. High up at the back were graceful sprays of *Cymbidium Lowianum* and two *Cœlogyne* Dayana, with drooping racemes of whitish flowers marked with sepia-brown. At one end was a fine spike of *Cœlogyne pandurata*, and near it a group of *Cypripedium niveum* and others of the class, *C. niveum* "The Duke" was a very fine flower; *C. Godefroyæ leucochilum* and *C. bellatulum*, extra good; *C. callosum* Sanderæ, *C. Maudisæ*, a very fine *Odontoglossum ardentissimum*, *O. amabile*, &c., all grown to perfection, and the group was brightened with scarlet and purple *Masdevallias*.

Mrs. STONYFORTH, Kirk Hammerton Hall, Yorkshire, showed an enormous specimen of *Dendrobium thysiflorum*, literally covered with fine heads of bloom, and for which a Cultural Commendation and Silver Banksian Medal were given.

Messrs. JAS. VEITCH & SONS, Royal Exotic Nursery, King's Road, Chelsea, showed *Cattleya Mossiæ* Rosalind, having three very large white flowers, with a slight blush on their broad crimped-edged labellums; also two plants of their new and fine *Brasso-Catt.-Lælia* Veitchii.

H. L. BISCHOFFSHEIM, Esq., Warren House, Stanmore (gr. Mr. Doig), staged a very effective group of excellent varieties of *Cattleya Mossiæ*, *C. Mendelii*, *Lælia purpurata*, &c., together with *Cypripedium bellatulum*, *Brasso-Cattleya Digbyano-Mossiæ*, *Odontoglossum citrosum* album, &c.

AWARDS.

FIRST-CLASS CERTIFICATE.

Lælio-Cattleya Golden Glory (*L.-C. Zephyra* x *Mossiæ Reineckiana*), from Major G. L. HOLFORD, C.I.E., C.V.O., Westonbirt, Tetbury (gr. Mr. H. G. Alexander). A very fine hybrid, with bright golden yellow flowers, with the front of the lips rose-crimson (see fig. 152).

Miltonia vexillaria, *Westonbirt variety*, from Major G. L. HOLFORD. A grand form and a very near approach to the famous *M. v. Memoria* G. D. Owen, its large rose-tinted flowers having the same rich vinous purple mask at the base of the lip; the colour, however, is rather lighter and shows more crimson than in the form mentioned.

Odontoglossum crispum Solum, from Messrs. SANDER & SONS, St. Albans. This remarkable form stands alone, as its name implies, there being no other with the remarkable, almost wholly dark ruby-purple lip. The sepals and petals are white, with an occasional blotch of the same colour as the lip.

Odontoglossum crispum xanthotes, *White's variety*, from Messrs. SANDER & SONS. Florally the best of its class, it has the broad segments of the best type of *O. crispum*. Flowers, white, with orange crest to the lip, and some orange-coloured spotting on the sepals and petals.

Cypripedium tibeticum, from Messrs. JAS. VEITCH & SONS, Royal Exotic Nursery, King's Road, Chelsea. The very handsome, hardy species introduced by Messrs. JAS. VEITCH & SONS through their collector, Mr. E. H. WILSON, and which was well illustrated in the *Gardeners' Chronicle*, June 2, 1906, p. 347. Flowers large, the sepals and petals tessellated with dark purple, the globose labellum chocolate-purple.

Odontoglossum ardentissimum Robsona, from Mr. JOHN ROBSON, Altrincham, Cheshire. A grand novelty and a great advance on other forms in size, substance, and colour, and worthy to rank with all first-class *Odontoglossums*. The greater part of the segments were of a bright crimson-purple; the margin and tips white.

Odontoglossum gandavense (*ardentissimum* x *Vuylstekeæ*), from Monsieur CHARLES VUYLSTEKE, Loochristi, Ghent. A fine hybrid of exquisite shape, the greater part of the segments of a peculiar rose-purple colour, the margin of the flower white.

Odontoglossum eximium King of England, from Monsieur CHARLES VUYLSTEKE. Flowers claret colour, with white margin and tips to the segments.

Odontoglossum caruleum (parentage unrecorded), from Monsieur CHARLES VUYLSTEKE. A new colour in *Odontoglossums*, the greater part of the flower being violet colour, with a white ground.

AWARD OF MERIT.

Cattleya Mossia Princess of Wales, from Major G. L. HOLFORD, C.I.E., C.V.O. (gr. Mr. H. G. Alexander). A magnificent form of typical *C. Mossia*, with large rose-coloured sepals, petals, and broad ruby-purple lip having an orange-coloured disc and bluish-white margin.

Odontoglossum Thompsonianum superbum (Edwardii $\times$ crispum), from W. THOMPSON, Esq., Walton Grange, Stone (gr. Mr. Stevens). Flowers claret colour, with pale lilac margin and tips.

Brasso-Lalio-Cattleya Lido (B. Digbyana $\times$ L.-C. Henry Greenwood), from Monsieur CHAS. MARON, Brunoy, France. Flowers large and of good shape, rosy-lilac, with a deep fringe to the very broad labellum.

MISCELLANEOUS PLANTS.

GROUPS.

Messrs. SUTTON & SONS, Reading, filled the whole end of the large tent with varieties of florists' flowers. The group was broken by a central oval bay, composed of the stellata or star type of *Cineraria*, and on either side were banks of Herbaceous *Calceolarias*, tuberous-rooting *Begonias*, and *Gloxinias*, finishing at either end with heavily-flowered plants of *Schizanthus Wisetonensis*. The group also found space for hybrid *Tobaccos* (*Nicotiana*) in a variety of colours, *Nemesia strumosa*, *Streptocarpus*, and other greenhouse subjects. The whole was staged in the best possible manner, with a few foils of *Palms*, *Grevillea robusta*, ornamental grasses, &c., and it was edged with a grass verge, *Caladium argyrites*, and *Ficus repens*.

Messrs. HUGH LOW & CO., Bush Hill Park, Enfield, showed greenhouse flowers, including *Gerbera Jamesoni*, *Ericas* in variety, *Boronia polygalæfolia*, tiny plants of *Azalea rosæflora*, very freely flowered, the colour being pink; *Pimelia*, *Hendersoni*, *Metrosideros floribunda* Ferns, *Roses*, &c.

Messrs. H. CANNELL & SONS, Swanley, showed large-flowered *Calceolarias* of the herbaceous type, hybrid *Streptocarpus*, a desirable strain of *Gloxinias*, exquisite small pot plants of *Phyllocactus phyllanthoides* var. *German Empress*, with pink flowers, a batch of the very finest varieties of *Cannas*, including the following new kinds: *Hermann Aldinger*, a very big crimson-coloured flower; *Gaekwar* of Baroda, bright scarlet spots on a yellow ground, a very choice flower; *Frau E. Kracht* (salmon). *Mephisto* is not new, but it is the darkest of all the race, being deep crimson. As a background to this very pretty exhibit was a row of heavily-flowered pillar *Roses*.

Messrs. JAMES CARTER & CO., High Holborn, displayed a very fine group of greenhouse flowering plants, staged in a very pleasing manner. They had excellent *Cinerarias* of the stellata or "star" type, a fine batch of *Gloxinias*, a double-flowering variety of *Lobelia compacta*, a choice strain of *Petunias*, tuberous-rooting *Begonias*, also *Carnations*, *Primula obconica*, *Schizanthus*, and a well-furnished rockery.

Messrs. JOHN PEED & SON, West Norwood, London, S.E., displayed a very large number of *Gloxinias*, all excellently flowered and exhibiting the very best cultural skill. The plants were almost all named varieties. Countess of Ilchester is one of the very best exhibited, a profuse bloomer and good grower; the colour is mauve or heliotrope, and the throat white. Countess of Carnarvon is very similar to the foregoing, save that the colour is rose. *Empress of India* is a purple flower of very large size; *Purity*, white; and *Queen Maud*, a new spotted variety.

Mr. W. ICETON, Putney, showed a batch of *Lily-of-the-Valley* in a setting of *Astilbe* (*Spiræa*), *Saxifraga corymbosa*, *Ericas*, and yellow *Azaleas*. The *Lily-of-the-Valley* was exceptionally fine. Mr. ICETON also furnished the top end of the centre tent with similar plants.

Messrs. JAMES VEITCH & SONS, Royal Exotic Nursery, Chelsea, exhibited a large group of ornamental foliage plants of stove and greenhouse subjects, interspersed with a few *Cattleyas*, *Anthuriums*, &c. *Anthurium crystallinum*

was represented by a magnificent specimen; there were also many handsome *Caladiums*, with foliage large and splendid in colour; tall *Codiaeums* (*Crotons*), choice Ferns, including the new *Nephrolepis exaltata* var. *todeaoides*; *Davallia tenuifolia* var. *Veitchiana*; *Medinilla magnifica*, in flower; large plants of *Nepenthes Mastersiana* and *N. sanguinea*, on tall pedestals; and a host of other beautiful subjects.

As a separate group in the same tent, Messrs. VEITCH exhibited many new and rare plants. *Magnolia parviflora* has a brilliant setting of red stamens in a pure-white perianth. Large standard plants of *Rhododendron* "Pink Pearl" were a feature; *Vitis megalophylla*, *V. Thomsoni*, and *Actinidia chinensis* are good climbing plants; and *Lonicera tragophylla* is another plant of this type of recent introduction; the flowers of the last-mentioned are yellow. The group also contained large-flowering *Clematis*, an assortment of *Azaleas*, *Eremurus*, *Primulas*, *Viburnum rhytidophyllum*, figured in *Gardeners' Chronicle*, June 30, 1906, p. 418, &c., &c.

Messrs. JAMES VEITCH also displayed an assortment of greenhouse flowering plants. Hybrid *Streptocarpus*, with flowers a shade of carmine-crimson, were noticed; also a handsome batch of *Phyllocactus*, some pretty hybrid *Gerberas*, *Kalanchoe Kewensis*, *Cinerarias*, *Blandfordia nobilis*, a rose-coloured form of *Lobelia tenuior*, and a host of other fine things.

Messrs. SANDER & SONS, St. Albans, gave prominence to a very large plant of *Encephalartos* in a group of choice stove foliage plants. *Dracæna Broomfieldii* superba has beautiful white striations and a similar margin, the centre being pale green. *Anthurium Scherzerianum*, *Phoenix Roebelinii*, *Bougainvillea Sanderiana* variegata, *Dracæna Godseffiana*, *Polypodium Knightiae*, *Pandanus pacificus*, and *Furcraea Watsoni* are other rare and beautiful plants exhibited in this group.

Messrs. WILLIAM BULL & SONS, King's Road, Chelsea, displayed a group of ornamental-leaved exotic plants. Some very fine specimens of *Dracæna Victoria* were prominent, notably a handsome plant in the centre of the group; also *Caladiums*, *Alocasias*, *Codiaeums* (*Crotons*), *Aralia Chabrieri*, tree Ferns, *Phyllotænum Lindenii*, *Bertolonias*, *Nepenthes*, *Palms*, &c.

The HORTICULTURAL COLLEGE, Swanley, showed well-grown plants of *Schizanthus Wisetonensis*, with flowers of a pleasing rose colour. Intermingled in the group were herbaceous *Calceolarias* and Ferns.

Messrs. HEATH & SON, Cheltenham, displayed handsome varieties of *Regal* and *Show Polargoniums*, together with plants of *Streptosolen Jamesoni*, very profusely flowered.

THE CRAVEN NURSERY CO., Clapham, Lancaster, showed pots plants of *Schizanthus Wisetonensis*.

WILLIAM R. CHAPLIN, Joynings Nursery, Waltham Cross, had small plants of a well-selected strain of garden *Petunias*.

WICKHAM NOAKES, Esq., Croydon (gr. Mr. W. Howarth), exhibited large plants of Herbaceous *Calceolarias* in pots.

Mr. T. A. HAMMERSTON, Epping, Essex, displayed a new double-flowered *Zonal Pelargonium*; name, *Pride of Essex*. The colour of the flowers is pink.

Clematis.—Messrs. RICHARD SMITH & CO., Worcester, displayed a very large group of large flowering *Clematis*. The plants were balloon-trained, taller specimens being at the back, and smaller plants with Ferns, *Anthuriums*, *Saxifraga corymbosa*, tiny *Maples*, and other subjects in the foreground. Among the more notable of the *Clematis* were *C. purpurea elegans* (lavender), *Gloire de St. Julien* (a large flower of fine form, with the palest suffusion of pink-white), *Venus vitreæ* (a double form), *Nellie Moser*, *Mlle. Edouard Andre* (vinous red), *purpurea elegans*, *King Edward VII.*, and many others.

Mr. L. R. RUSSELL, Richmond Nurseries, Richmond, Surrey, exhibited well-trained plants of showy *Clematis* in all the more notable and finer varieties. At the back overhung pillar plants of *Wistaria sinensis* and tall *Palms*, and at the front a bright edging of *Eurya latifolia*, and the red-flowered *Boronia heterophylla* var. *Albert Victor*.

Rhododendrons and Azaleas.—Messrs. JOHN WATERER & SONS, LTD., Bagshot, Surrey, staged a group of *Rhododendrons* in the

form of a bank; perhaps a little too crowded for the best effect, but remarkable for the quality and variety of colouring and general culture. A conspicuous place was given to the beautiful *Pink Pearl* variety, among which was seen a great difference in the degree of colouring, some being very pale—almost white; *Strategist* (rose-pink), *Duke of Connaught* (red, with a pale interior), *Duchess of Connaught* (white, with yellow spots on the upper petal), *John Waterer* (one of the handsomest of the red-flowered kinds), *Mrs. William Agnew* (a delicate pink, with deeper-coloured margins), *Baroness Henry Schroder* (white, with purple spotting), *Minnie*, *concessum*, &c.

Messrs. R. & G. CUTHBERT, The Nurseries, Southgate, Middlesex, staged a charming group of *Azaleas* of the mollis, *altacelerensis*, and *Ghent* types. The group presented a sheet of colour, the plants being covered in their delicate-tinted flowers in yellow, pink, red, salmon, white, and other shades. *Pallas* (orange) and *Fanny* (pink) are two beautiful varieties of *A. indica*, and most profuse in their flowering. *Mrs. A. E. Endy* (yellow), *Dr. Reichenbach*, *Mme. Anthony Koster* (new), and *Alphonse Lavalée* are but a few of the varieties represented in this pleasing exhibit.

Mr. CHAS. TURNER, Royal Nurseries, Slough, staged two dozen pyramidal-trained plants of *Azalea indica* in a setting of showy *Maples* and Ferns. The plants were covered to their bases with flowers, and included such handsome varieties as *Roi de Hollande* (a remarkably profuse bloomer), *grandis*, *Perle de Deleberg* (white), *Rosa Bonheur* (double), *Helene Thelemann* (pink), *Mme. Van Houtte* (pink, with a white edging), *Mrs. Turner*, *Hexe*, &c.

Messrs. WM. PAUL & SON, Waltham Cross, Herts, exhibited trusses of many beautiful varieties of hardy *Rhododendrons*.

Messrs. W. H. ROGERS & SONS, Southampton, showed varieties of *Rhododendrons* and *Azaleas*.

Caladiums.—Messrs. JOHN PEED & SONS, West Norwood, London, S.E., exhibited showy *Caladiums*, all beautifully coloured. The gradations of colour ranged from the palest green through darker shades to deep crimson, some of the varieties being maculated with deeper spottings, and others having pronounced veining in crimson, green, pink, and other shades set in a paler lamina. A selection of the varieties shown includes *Sir Henry Irving*, *John Peed*, *Edith Luther* (new rose), *Marquis of Camden*, *Mr. John Box*, *Mrs. Iceton* (new, pale green), *Silver Queen* (the very palest green), *Triomphe de Comte* (a remarkably fine flower, handsomely coloured), *May Archer* (new), &c.

Messrs. JOHN LAING & SONS, Forest Hill, West Norwood, displayed choice varieties of *Caladiums*, making a very good display with these showy-leaved subjects. Among the finer kinds in the group were *Triomphe de Comte*, red, with green markings; *Mme. Imbert Kachlin*, greenish-yellow; *Rose Laing*, a beautiful kind, with rose veins on a greenish-yellow-coloured ground; *George Berger*, a splendid leaf; *Excellent*, red in the centre of the lamina, and edged with green spotted with silver; *Gerard Dow*, red, &c.

Hippeastrums.—Major G. L. HOLFORD, West-birt, Tetbury, Gloucestershire (gr. Mr. A. Chapman), showed a selection of his fine strain of *Hippeastrums* (*Amaryllis*). The plants were staged sufficiently apart to display their beauty, and suitable foils, such as Ferns, *Palms*, &c., were included in the exhibit. A selection of the varieties, most of which have been already described in our pages, embraces *Isis* (almost pure white), *Homer* (red), *Juno* (white ground, streaked with red), *Firelight* (scarlet), *Miltiades* (crimson), *Rob Roy*, *Hamlet*, &c.

Messrs. R. P. KER & SONS, Grassendale, Liverpool, also exhibited *Hippeastrums*, the group adjoining that last mentioned. The plants were sturdier and dwarfer than those in the former exhibit, but they were none the less beautiful, although, perhaps, a little too crowded. A variety named *Dreadnought* is of remarkable size: it measured little less than a foot across, but the colour is not of the best, being a weak shade of red. *Pink Pearl* is a fine flower, aptly named; *Sylvia* is almost pure white, and *alba perfecta* is quite an albino. *Lord Chancellor*, *Black Prince* (crimson), and *Neptune* are other excellent varieties seen in this exhibit.

CARNATIONS.

All the exhibitors staged very fine blooms. The Guernsey growers appear to obtain better colour in their flowers than home growers; this is especially seen in such varieties as Enchantress and others of bluish and pink shades.

Mr. H. BURNETT, Guernsey, staged a fine group, the variety Mrs. H. Burnett being of the best quality, also the new Marmion (see Awards) and Mikado (a shade of heliotrope). The American varieties, especially R. Craig, were good, and there were also several seedlings of promise.

Messrs. BELL & SHELDON, Guernsey, exhibited flowers of the American type. Helen Goddard (rose pink, a fine variety), President, Lady Boun-

Messrs. JAS. VEITCH & SONS, LTD., Chelsea, made an extensive exhibit, chiefly of the American type: the Pink Mrs. Patten is a most promising variety. The leading sorts of winter-flowering Carnations were well shown in this display.

Mr. C. TURNER, Slough, put up a good group of pot plants representing American, Souvenir de la Malmaison, and other varieties.

Messrs. CUTBUSH & SONS, Highgate, were extensive exhibitors, all classes being well shown in pot plants. The variety King Arthur was remarkably fine, as were also their examples of Souvenir de la Malmaison.

Mr. C. F. WATERS, Balcombe, Sussex, ex-

the leading American sorts in well-developed blooms; Jessica, R. Craig, White Perfection, and others were very fine.

Mr. A. F. DUTTON, Iwer, Bucks, exhibited in his usual good form his improved White Lawson and other leading American sorts, all exhibiting very best culture.

Mr. ENGELMANN, Saffron Walden, was another good exhibitor of the American sorts. Fiancée has been condemned by some growers, but as seen here it was very fine. The variety Mrs. W. T. Omwake was also good. Several seedlings were shown by Mr. ENGELMANN.

The Duke of PORTLAND, Welbeck Abbey (gr. Mr. J. Gibson), put up a fine group of pot plants, chiefly of Souvenir de la Malmaison varieties, of which Princess May was prominent.

Sir S. SCOTT, Brackley (gr. Mr. Tupper), staged good plants of Cecilia, Lady Hermione, and others.

THE ROSES.

The large marquees was better filled with Roses, shown as plants, than on any previous occasion. One of the largest and most varied groups was that shown by Messrs. W. PAUL & SON, of Waltham Cross Nurseries. The main idea in the arrangement of this exhibit was that of a sloping bank of bush Roses, and these were excellent for the size and fine condition of the individual flowers and abundance of healthy foliage; dotted among them at wide distances were standard Roses, and columns of such climbing varieties as Lady Gay, Kathleen, Hiawatha, &c., and the group had a backing of the same varieties. The new hybrid Tea Madame Melanie Souper had an immense bloom of a light flesh tint, a filbert-shaped central mass of petals, and very large, circular guard petals. Dr. William Gordon is a large—sometimes very large—Rose of a bright pink tint, of good form, and very full in the centre.

Mr. CHAS. TURNER, Royal Nurseries, Slough, showed dwarf and climbing Roses extensively, Crimson Rambler, Lady Gay, &c., being dotted about among the former as "starers." Standards of Souvenir de Pierre Notting, Maman Cochet, &c., were employed in a similar way. The effect was pleasing.

Messrs. PAUL & SON, The Old Nurseries, Cheshunt, made with a corner group a great show of Rambler and Polyantha varieties, and of Hybrid Teas as standards, arranged among the dwarfier Roses shown in pots. Of newer varieties there were observed Souvenir de Rosieriste R. Vilin, a massive white, of pleasing form, solid and full. Cherryripe pleased us by reason of its bright crimson tint that is marred by a conspicuous eye; Sénateur St. Romme possesses a solid form, and a flesh tint; Dean Hole is a nice bright pink Rose, with the shape of Niphetos; Grand Duchess Alexandra is a fine, light flesh-coloured flower; Nellie Johnstone has a filbert-shaped bloom of moderate size and of light rose tint. The bloom, when in the half-open state, is a charming one.

The corner group facing the last was set up by Messrs. W. CUTBUSH & SON, of Highgate and Barnet. In this exhibit the Roses were in combination with "Malmaison" Carnations. Climbing and Polyantha Roses were finely bloomed, and these formed the background of the group.

Messrs. B. R. CANT & SONS, The Old Rose Gardens, Colchester, exhibited Roses, arranged in the form of a bank on a table, the back rows consisting of Ramblers Lady Gay, Mrs. T. W. Knight, Evangeline, Babette, Nance Christy, Crimson Rambler, Minnehaha, a pretty double-flowered, pink variety; Dorothy Perkins, and others. The middle foreground was filled with various climbing Roses, and species having single flowers, as Atropurpurea, Altaica, Leuchstern, and Killarney; and the front was furnished with boxes of cut bloom. Among these very fine blooms of the best show varieties were conspicuous, Teas and Hybrid Teas being in the majority.

Messrs. F. CANT & CO., Braiswick Nurseries, Colchester, made an imposing show of Rambler and Polyantha Roses in great variety, such bright-looking Roses as Hiawatha being made much use of for the forming of arches and pillars. Trier is a semi-double white flower, with yellow anthers; Gruss an Zabern is more double, and not unlike Felicité et Perpetué; Eugénie Lamesch is a semi-double Polyantha variety, pale lemon coloured; Philadelphie Rambler has a very bright crimson tinted, and

FIG. 151.—ODONTOGLOSSUM X PHOEBE MAGNIFICUM, AS EXHIBITED BY MESSRS. CHARLESWORTH AND CO. AT THE TEMPLE SHOW.

tiful (still one of the best "whites"), President (crimson), and Enchantress were all remarkable for the size and colour of the flowers.

Mr. S. MORTIMER, Farnham, Surrey, staged a fine lot of blooms. Harry Fenn was the best crimson variety displayed in this group, and Victory the best scarlet; Adonis, White Perfection, and most of the other American sorts were all finely shown.

Mr. W. H. PAGE, Hampton, showed a fine assortment of these popular flowers, having such standard kinds as President Roosevelt (crimson), White Lawson, Mrs. T. W. Lawson, and Enchantress.

hibited well-grown Carnations, his varieties specially worthy of note being H. Elliott, G. Steel, and Souvenir de la Malmaison "Princess May."

Messrs. HUGH LOW & CO., Bush Hill, Enfield, were large exhibitors, having a fine exhibit in the tent and another in the open. Large specimens of "Malmaison" varieties were a feature; Princess May was finely shown, Lady Rose, Britannia, Floriana, Robt. Craig, and all other sorts were well shown.

Messrs. T. S. WARE, Feltham, had some fine blooms of Leander among others.

Messrs. R. H. BATH, LTD., Wisbech, exhibited

flowers that are fairly full in the centre. *Perle d'Or* is pretty as a bud. As cut blooms shown in boxes many of great beauty were observed in Hybrid Teas. Particularly fine were the blooms of *Lady Roberts*, pleasing in shape, and tinted with creamy-orange; *Kaiserine Augusta Victoria*, J. B. Clark, Oscar Cordel, Mrs. Sharman Crawford, Mme. Jean Dupuy, David Harum, and Golden Gate were shown in exquisite examples.

Messrs. H. CANNELL & SONS, Swanley Junction, showed a large number of Rambler Roses as a background to their exhibit of *Streptocarpus*, *Calceolarias*, &c.

BEGONIAS.

Tuberous-rooting Begonias were a great feature, and the advance made in these flowers is surprising. Double varieties were most noticeable, not only in size, but also in the form.

Messrs. T. S. WARE, Feltham, exhibited a very fine collection of double-flowering varieties in many fine shades of colours. Varieties with crimped petals were remarkable, and three new ones were granted awards. The whole of the plants staged were of remarkable quality, and are deserving of the highest praise.

Messrs. R. B. DAVIS & SONS, Yeovil, staged a good collection, including both double and single-flowering varieties of the finest types.

Mr. J. R. BOX, West Wickham, made a good exhibit, fringed and fluted varieties being a great feature.

Messrs. BLACKMORE & LANGDON, Bath, made a fine exhibit of remarkable quality, and it would be difficult to imagine anything more perfect than some of his flowers.

Mr. A. I. GWILLIM, New Eltham, did not stage a large exhibit, but his flowers were of the highest quality. An Award of Merit was given to his seedling Mrs. J. C. Gwillim; *Pride of Eltham*, a rich crimson variety, is also worthy of note.

Messrs. J. LAING & SONS, Forest Hill, made a good exhibit, having double, single and fringed varieties of the best types.

HERBACEOUS AND ALPINE PLANTS.

HARDY plants have never before been seen at any Temple Show in such numbers and of such good quality, whilst in the method of their staging we can also record an advance.

Messrs. WALLACE & Co., Colchester, displayed a group of hardy plants in the big tent. The effective and pleasing arrangement of the plants surpassed all their former efforts, the general design being a well-conceived piece of rockery, on which were planted bold masses of *Eremuri*, a rich display of Lilies, of which the more notable examples were *L. Hansonii*, *L. monadelphum*, and *L. testaceum*; also many fine *Ixias*, cushion and other Irises, *Cypripediums*, &c. Shady peat-beds contained *Trilliums*, *Dodecatheons*, *Adiantum pedatum*, and other bog-loving plants.

Messrs. GEO. JACKMAN & SONS, Woking, had a very extensive exhibit of hardy things, in which *Trollius* (globe flowers), hybrid *Columbines*, and *Pyrethrums* were leading features. *Ranondia pyrenaica alba* was also very fine, and the group also contained many choice hardy *Cypripediums*, *Meconopsis cambrica*, *Eremuri*, *Early Gladioli*, Spanish and other Irises. At one end of the exhibit Messrs. JACKMAN displayed a fine group of large-flowering *Clematis*.

A fine specimen of *Echium callithyrsum* was exhibited by Miss B. TALBOT, Little Gaddesden House, Berkhamsted. (Cultural Commendation.)

Messrs. BARR & SONS, Covent Garden, London, W.C., had a large exhibit of hardy plants, including Lilies, Irises, *Ixias*, and Tulips, the latter representative of the old English Darwin, cottage, and May-flowering kinds. Other interesting things in the group were *Viola pedata*, *Trillium uniflorum*, a very charming kind; *Primula farinosa* and *Incarvillea grandiflora*. Cushion Irises, together with others of the hybrid *Regelio-cyclus* type, gave a most interesting touch of colour to the group.

THE GUILDFORD HARDY PLANT COMPANY, Guildford, had, as on previous occasions, a rockery, in which were planted choice Alpine and rock-garden shrubs. *Daphne cneorum* was very beautiful, as were also *Ranondias*, *Haberleas*, Alpine and other *Phloxes*, choice *Saxifragas*, *Cypripediums*, &c.

A small exhibit of rock-garden plants was arranged by the Misses KIPPING, Hulton, Essex, a large number of free-flowering Alpines being employed to good advantage.

Mr. M. PRICHARD, Christchurch, Hants., had an array of the best hardy, Alpine and herbaceous plants in flower. *Gentiana verna* was particularly fine, while *Ranondias*, and the Alpine *Asters*, *Ledum Lyoni*, *Dodecatheons*, *Saxifraga MacNabiana* were all very pleasing. Greater masses of colour were seen in the several forms of *Scilla campanulata*, *Hyacinthus amethystinus*, brilliant *Poppies*, *Eremuri*, Irises, *Pyrethrums*, *Pæonies*, &c. *Menyanthes trifoliata* (*Bogbean*) was in splendid condition. Tulips also were displayed in excellent condition.

Mr. FRANK LILLEY, St. Peter's, Guernsey, exhibited *Ixias*, *Sparaxis*, *Iris*, *Anemones*, &c.

Messrs. BAKERS, Wolverhampton, staged a large and varied group, in which were bold clumps of *Eremuri*, *Columbines*, and other tall subjects, together with a nicely-arranged and well-planted rockery, in which *Trilliums*, *Phloxes*, *Cypripediums* and the like were associated. The same firm exhibited a very extensive assortment of *Violas*, *Pansies* and *Pelargoniums* as cut flowers.

Mr. N. LOWIS, Leversdown, Bridgwater, displayed choice "Poppy" *Anemones*.

Mr. H. C. PULHAM, Elsenham, Essex, arranged an exhibit of Alpine plants, *Daphne cneorum* and *Androsace Clumbyi* being exceedingly good.

Anemones of the *A. coronaria* group were freely displayed by Messrs. REAMSBOTTOM & Co., Geashill, King's Co., Ireland.

Messrs. PAUL & SON, The Old Nurseries, Cheshunt, had a small exhibit of hardy plants, including Tulips, *Pæonies*, *Poppies*, *Geums*, &c., in company with Alpines.

Many fine varieties of Oriental *Poppies* were well displayed by Mr. W. J. GODFREY, Exmouth, varieties with crimson and terra-cotta shades being plentiful. Adjoining the *Poppies* were many varieties of Zonal and show *Pelargoniums*.

Mr. G. REDMAN (The Craven Nursery), Clapham, Lancaster, had a most delightful gathering of the choicest of Alpines arranged with much taste in a setting of well-weathered mountain limestone; the whole arrangement gave evidence of experience and skill. The exhibit was crammed with rare things, a few of which are *Daphne rupestris*, a mass of rich pink; *Haberlea rhodopensis virginialis*, *Edraianthus serpyllifolius*, a very handsome form; *Saxifraga aizoon rosea*, *S. a. lutea*, a rare kind; *Primula farinosa alba*, *Dianthus glacialis*, *Tiarella unifoliata*, &c. The Vernal gentian was simply a carpet of blossoms. The exhibit was one of the most fascinating groups of rare Alpines we have seen.

Messrs. RICHARD SMITH & Co., Worcester, contributed some *Pæonies*, *Pyrethrums*, Irises, and other showy and good perennials.

Ixias sent by Major-General CAMPBELL, Lieut.-Governor of Guernsey, were very pretty.

THE KING'S ACRE NURSERY COMPANY, Hereford, had an exhibit of Alpines of the showy and free-flowering class, together with some brilliant masses of *Gentiana verna*, *Cheiranthus allioni*, &c.

Mr. HOWARD H. CRANE, Highgate, exhibited tufted and other *Pansies*. In all some fourteen varieties were staged, the blossoms arranged in shallow pans, looking far more natural than in the formal sprays as heretofore. We were pleased to note the change.

Messrs. G. & A. CLARK, Dover, had a large and varied assortment of the best hardy perennials in season, finely grown and well arranged. The masses of colour were most effective.

A rockery exhibit arranged and planted by Messrs. J. CHEAL & SONS, Crawley, attracted much attention, both by reason of its form and the effective manner of its planting.

Mr. B. LADHAMS, Southampton, brought a large collection of *Geums*, *Lupins*, *Iris*, and *Pyrethrums*, and Mr. KERSWELL displayed the *Gentianella* in boxes.

Anemone coronaria in variety from Mr. J. HARRIS, Blackpill, Swansea, made a fine show, the variety *The Bride* being unusually good.

Messrs. CARTER & Co., High Holborn, had arranged a rockery in the opening of No. 3 tent.

A group of herbaceous plants shown by Mr. AMOS PERRY, Enfield, was very good. *Eremuri*, *Poppies*, *Gerberas*, *Cushion*, and other Irises, *Pæonies*, Lilies, and a host of other things were

in splendid condition. *Phlox canadensis*, Perry's variety, still continues a great favourite.

Messrs. G. BUNYARD & Co., Maidstone, had a splendid lot of the more showy hardy plants, such as *Cushion Irises*, Tulips, *Geum*, *Poppies*, *Pæonies*, *Primula japonica*, *Pyrethrums*, &c.

Messrs. T. S. WARE & Co., LTD., Feltham, had a mixed group, in which *Carnations*, Alpines, and choice hardy plants were seen to advantage. *Carnation Leander* was very fine.

The Hon. A. H. T. de MONTMORENCY, Carrickmines, Dublin, staged a fine exhibit of old English Tulips in the best varieties.

Mr. R. C. NOTCUTT, Woodbridge, displayed a rich and varied assortment of perennials of such subjects as *Trollius*, *Poppies*, Lilies, and *Pyrethrums*.

As on other similar occasions, the rockery exhibit of Messrs. BACKHOUSE & SON, York, was quite a feature. Many choice Alpines were arranged with skill, the flower-laden mountain pasture in miniature making a very pretty scene.

Mr. G. REUTHE, Keston, Kent, had a large assortment of Alpines and choice flowering shrubs, and these, with a big display of Tulips, made one of the most varied and interesting of the many hardy plant exhibits. *Embothrium coccineum*, *Crinodendron Hookeri*, *Magnolia Watsoni*, and a choice lot of *Rhododendrons* were noted, and *Gentians*, hardy *Orchids*, *Saxifragas*, &c., were in abundance.

The Misses HOPKINS, Barming, near Maidstone, had an interesting exhibit, chiefly of Alpines arranged on rockwork. *Primula luteola* was very fine.

Messrs. KELWAY & SONS, Langport, Somerset, had a rich display of *Pæonies* and *Pyrethrums*, each in considerable quantity and variety.

Messrs. STORRIE & STORRIE, Dundee, had an interesting lot of *Primulas* and *Polyanthus*, showing the development along certain lines by crossbreeding and evolution.

A large group of *Lathyrus Sibthorpii*, a species with deep rosy-lilac blossoms, came from Mr. BAKER, Oxford.

SOME CUT FLOWERS.

Mr. ROBERT SYDENHAM, Tenby Street, Birmingham, had a large exhibit of Sweet Peas, *Lily of the Valley*, &c.

Messrs. H. B. MAY & SONS, Edmonton, brought a fine array of cut *Pelargoniums* of such fine varieties as *Hall Caine*, *Lord Kitchener*, *Gloriosa*, &c.

Mr. C. F. WATERS, Balcombe, Sussex, staged a most beautiful lot of *Carnations*, *Lady Carlisle*, *Enchantress*, and *Pride of Exmouth* being notable examples.

Mr. H. J. JONES, Lewisham, had a big display of *Pelargoniums* and Sweet Peas, very large and representative gatherings of each being staged. Sweet Peas from Mr. J. UNWIN, Histon, Cambs., were also fine, the white variety *Nora Unwin* being very good. There were many promising seedlings in the group.

Messrs. R. H. BATH, LTD., Floral Farms, Wisbech, had a large group of handsome flowers of Tulips and *Carnations*.

Messrs. CARTER, PAGE & Co., London Wall, E.C., had a large collection of *Fuchsias*, *Antirrhinums*, *Phlox Drummondii*, *Dahlias*, and *Pelargoniums*.

Mr. W. A. MYERS, Swanmore House, Bishop's Waltham (gr. Mr. E. Molyneux), staged a fine collection of double and single Lilac, the trusses and individual blossoms being extremely fine.

Messrs. WALLACE & Co., Colchester, staged a large group of Darwin and other Tulips in excellent condition.

Mr. A. F. DUTTON, Iver, Bucks, had Tree *Carnations* in the best condition, many of the blossoms being of quite an exceptional large size.

Messrs. W. H. ROGERS & SONS, LTD., Southampton, had cut blooms of *Rhododendrons*, *Azaleas*, &c., in considerable variety.

Messrs. G. STARK & SONS, Great Ryburgh, Suffolk, had a large assortment of Sweet Peas, *Pansies*, &c. The *Pansies* were of much merit.

Cut *Pelargoniums* formed the chief feature of an exhibit from Mr. VINCENT SLADE, Taunton, Somerset.

Sweet Peas from Mr. C. W. BREADMORE, Winchester, were unusually fine, the varieties *Helen Lewis*, *Etta Dyke* (a really splendid white), and *Mrs. Collier* (cream), being the best in a very extensive display.

Mr. S. MORTIMER, Farnham, set up a splendid lot of Marechal Niel Roses, arranged in front of choice Carnations.

Messrs. HOGG & ROBERTSON, LTD., Dublin, had a fine lot of Darwin and other late-flowering Tulips, the varieties Ixioides, Suzon (fine rose-pink), and Chameleon being noticeable in a huge display.

Messrs. DOBBIE & Co., Rothesay, staged Sweet Peas, Columbines, Pansies, Marigolds, and other flowers in many varieties. The Pansies were really a superb lot, and the colours noted in the hybrid Columbines were distinct and beautiful.

Messrs. ALEX. DICKSON & SONS, Belfast, had a magnificent display of Tulips, excellent in every way for so late a date. Clara Butt, the "Queen" of the rose-coloured Tulips; Gustave

by Messrs. E. W. KING & Co., Coggeshall, Essex.

FERNS.

There was an absence of any novelty, and none was entered for award, yet Ferns were well shown.

The group of *Nephrolepis todeacoides*, from Messrs. T. ROCHFORD & SONS, LTD., Broxbourne, attracted much attention, and the plants were certainly superbly grown, representing one of the most remarkable varieties we have of this now popular Fern.

Messrs. H. B. MAY & SONS, Upper Edmonton, put up a superb group. Space was limited, so they were obliged to elevate the plants in order to obtain the maximum room. The newer varieties of *Nephrolepis*, including *Whitmani*, *exaltata superba*, *todeacoides*, and others were well

and included *A. nidus*, a Fern introduced by this firm for market purposes. *A. Mayi* was shown in its best form. *Davallias* were represented by large specimens; *Platyceriums* included fine specimens of *P. grande*, *P. angolense* and other choice sorts. *Lomarias* were well shown, and included the bright-coloured *L'Hermieri*, but the bright-tinted Ferns were not quite so prominent as is usual at this exhibition.

EXHIBITS ARRANGED OUT-OF-DOORS.

Messrs. J. VEITCH & SONS, LTD., Royal Exotic Nursery, Chelsea, showed a large group alongside of the marquee, consisting of *Rhododendrons*, *Azaleas*, inclusive of *hybrida flore plena* in variety, *A. mollis* × *sinensis*, Rollison's *A. rosæflora*, double flowered and large. The

FIG. 152.—MAJOR HOLFORD'S LÆLIO-CATTELEYA "GOLDEN GLORY": COLOUR OF FLOWERS GOLDEN-YELLOW, WITH ROSY-CRIMSON MARKING ON LIP.

(Awarded First-Class Certificate at the Temple Show.)

Doré, Loveliness, Cherry Ripe, King's Court (bronze), and Gorgeous were all notable sorts in this exhibit.

LORD ALDENHAM, Elstree (gr. Mr. Beckett), had a beautiful lot of flowering shrubs—*Exochorda grandiflora*, Tree Pæonies, Honey-suckles, Azaleas, and many others.

Mr. HENRY ECKFORD, Wem, Salop, brought a fine gathering of Sweet Peas, the large collection containing many good things. Henry Eckford (pale orange) is a variety of very striking appearance.

A small, yet very interesting, gathering of old English Tulips came from Mr. J. MCKERCHAR, 35, Giesbach Road, Holloway.

Sweet Peas in large numbers were exhibited

shown. *Davallias* included *D. fijiensis*, *D. Veitchiana*, *D. ornata*, and many others. *Adiantums* were good, *A. Veitchi* being very bright in colour. *A. Farleyense* is always well shown by this firm. *Platyceriums* were a great feature. The same firm arranged in the open a large group of hardy British Ferns. The *Polypodiums* included some of the best plumose varieties. *Asplenium felix-fœmina* was also represented by some of the best crested forms. There were handsome *Scolopendriums*, *Polystichums* (*Aspidiums*), &c.

Messrs. J. HILL & SON, Lower Edmonton, had a meritorious group, and here again the plants were elevated, some being fully 20 feet above the ground level. *Aspleniums* were a great feature,

Rhododendrons were shown as bushes and standards, the standards being about 6 feet high, and every plant showed a wealth of bloom. The good qualities of *Philadelphus Lemoinei* *Boule d'Argent* was shown by a number of plants about 3 feet high grouped together in a basket. The *P. L. pavillon blanc*, a better thing, was likewise observed. Its white blooms are 1½ inches across, and very numerous. A nice "Judas" tree in a pot, well flowered, is uncommon. A good thing in *Viburnums* was noted in *V. tomentosum* *Mariesii*, the cut sprays shown being crowded with the white, single flowers in flat cymes. The graft-sport *Cytisus* × *Adami* was noted, the yellow and purplish flowers growing on shoots springing on the same stock.

Hydrangeas were numerous, and many species and varieties were represented. A good show was made with varieties of herbaceous Pæonies. *Incarvillea Delavayi* and *I. grandiflora* of deeper tint were noted in good flower; *Primula pulverulenta*, *P. Veitchii*, a new and excellent variety of *P. sibirica* (see fig. 147), *P. japonica* var., *P. x Unique*.

A natural-looking rockery was erected by Messrs. PULHAM & SON, and nicely planted by them with Alpines, dwarf Conifers, &c.

Mr. THOS. CRIPPS, nurseryman, Tunbridge Wells, exhibited large, pictorial trees, chiefly belonging to the genus *Acer*. Among them were many Japanese species and varieties, *Clematis*, *Rhododendrons*, *Azaleas*, and *Vitis*.

Messrs. J. WATERER & SONS, Bagshot, Surrey, showed *Rhododendrons* in much variety, among them Mrs. Tom Agnew, a delicate flesh-coloured flower, with a patch of light crimson spotting on the upper segment of the bloom; William E. Gladstone, Helen Waterer, a mass of *R. hybridum azaleoides*, some plants of *R. Baroness Henry Schröder*; of *R. George Storey*, a grand truss and pure white flowers; of *R. Mrs. E. C. Stirling*, puce, very large and fine; and of *R. Pink Pearl*, one of the finest.

Mr. L. R. RUSSELL, Richmond Nurseries, Richmond, Surrey, exhibited a great quantity of hardy trees and shrubs, such as species and varieties of *Acers*, *Fagus*, *Ivy*, *Vitis*, the pretty blue-flowered *Ceanothus dentatus*, good as a free-standing shrub or for covering a wall space; and Spanish broom, plants 1 foot high and free in flowering.

Messrs. PAUL & SON, The Old Rose Nurseries, Cheshunt, exhibited a group in which there were several fine new varieties of *Rhododendrons* of much beauty, viz., *Helen Paul*, *H. M. Arderne*, *Duke of York*, *Boadicea*, *R. Fortunei*, *Geo. Bennington*, several fine *Lilacs*, and large plants of *Hydrangea arborescens grandiflora* alba, pure white, and the plant free in flowering; shoots of *Cercis siliquastrum alba*, a faint tinge of purple showing in the flowers and betraying the origin of this sport; *Syringa* (*Lilac*) *persica alba*, and several fine varieties of *Lilac* of Continental origin.

Messrs. W. FROMOW & SONS, Nursery, Chiswick, showed Japanese *Acers*.

Messrs. RICHARD SMITH & CO., LTD., The Nurseries, Worcester, were also large exhibitors of these and other pictorial subjects, including some Conifers having variegated foliage, such as *Thuyas*, *Yews*, and *Cypressus*.

Messrs. J. CHEAL & SONS, Lowfield Nurseries, Crawley, exhibited ornamental trees from 3 feet up to 12 feet high, including *Quercus*, *Acer*, *Dimorphanthus mandshuricus*, *Sambucus*, *Fagus* in variety, *Vitis*, *Weigela*, *Rhododendron*, *Viburnum plicatum*, and a number of objects of the topiary art in *Buxus* and *Taxus*.

W. ROUFELL, Esq., Roupell, Park, West Norwood, showed four fine examples of *Polystichum angulare proliferum*.

Anchusa italica, Dropmore variety, in examples 5 to 6 feet in height, was shown by Mr. MAURICE PRICHARD, of Christchurch, Hants.

Messrs. H. B. MAY, The Nurseries, Upper Edmonton, had in an enclosed square a large bed of the finest *Verbenas*, excellent for pot culture and bedding out, some with white "eyes," others without, the flowers being of purple, blue, scarlet, and pink: all great improvements on the old varieties. Other plants noted were *Salvia coccinea Zurich*, *Lobelia* in three different colours; *Heliotrope Lord Roberts*, a capital dwarf variety for pot work; some richly coloured *Coleus*, Ivy-leaved *Pelargoniums* of strange new tints in the flowers; two new Zonal *Pelargoniums*, and a number of well-grown British Ferns.

Messrs. BARR & SONS, King Street, Covent Garden, exhibited miniature trees, an arrangement of Alpine and other rock plants on a flat surface, such as might be formed on a balcony or in a roof garden.

B. LADHAMS, LTD., 60, High Street, Southampton, showed *Lupin Rosy Morn*, *Anchusa "Opal"*, *Olearia stellulata*, floriferous little plants growing in pots; *Aquilegia vulgaris x glandulosa*, &c.

Mr. AMOS PERRY, Hardy Plant Farm, Enfield Chase, Middlesex, showed a variety of *Phlox canadensis*, different in tint, upright in growth, flowers longer than the type.

Messrs. W. CUTBUSH & SON showed many objects of topiary art, well grown, and showing years of culture and training.

Messrs. HUGH LOW & CO., Bush Hill Park Nurseries, Middlesex, showed a large group of "Malmaison" Carnations. A plant of *Princess of Wales* had 50 open blooms and flower-buds, and another 53.

Messrs. W. CUTBUSH & SON, as in some previous years, had constructed a rockery on a large scale, and well furnished it with suitable plants in a flowering state. As the planting had been liberally done, the plants being not singly planted but in colonies, the effect was good.

Messrs. DAVID RUSSELL & SON, Essex Nurseries, Brentwood, showed a group of miscellaneous plants. These consisted of *Azaleas* and *Acers* from Japan, *Rambler Roses*, *Clematis*, hybrid *Rhododendrons*, *Tree Ivies*, and many species of pictorial trees, &c. This firm showed *Rambler Roses* in variety, Japanese *Acers*, hardy *Azaleas*, hybrid *Rhododendrons*, *Euonymus*, *Brooms*, and *Viburnums*.

Messrs. F. CANT & CO. had what seemed to be overflow groups of *Rambler Roses*.

Messrs. BLACKMAN & LANGDON, Bath, showed their bedding *Begonia Argus*, a fine, bright scarlet variety of compact growth, having flowers of a double form and sufficient substance as to make a good out-of-doors subject.

Messrs. J. CARTER & CO., High Holborn, London, had an exhibit of Japanese or Chinese trees, Conifers, &c.

Messrs. HUGH LOW & CO. showed a collection of *Callistemons* of various shades of crimson, also a white one. The plants were plentifully covered with their bottle brush-like flower heads. The standard forms were particularly effective. Messrs. H. Low also exhibited some enormous fruits of *Strawberry Kentish Favourite*, and some plants in flower, in order to show its great cropping capabilities.

Floral Committee.

AWARDS OF MERIT.

Saxifraga aizoon rosea.—The most beautiful of the coloured section of the encrusted *Saxifragas*, and though as yet rare it is happily of a type that quickly increases. The purplish flower stalk is seen to advantage above the silvery rosette of leaves, and lends an enhanced beauty to the flowers. From Mr. FARRER, the Craven Nursery, Clapham, Lancaster.

Primula x Unique (*P. pulverulenta x P. Cockburniana*).—This valuable and interesting hybrid we may regard as the forerunner of a new race of hardy *Primulas*. The new-comer is especially welcome in that it embodies all that is good in both parents, and partakes much of the size of the seed parent (*P. pulverulenta*), and has something of the rich colouring of the other parent. The mealy character is maintained in the hybrid, and it has the freedom of flowering characteristic of *P. pulverulenta*. From Messrs. JAS. VEITCH & SONS, LTD., Chelsea.

Cytisus Firefly.—A very showy and good form of *C. Andreanus*. Shown by Messrs. R. W. WALLACE & CO., Colchester.

Papaver Princess Ena.—This is a beautiful seedling Oriental Poppy from the well-known Queen Alexandra variety. The flowers are of a medium size and are of a soft salmon shade, darker in the centre. A satin-like sheen is spread over the main colour, rendering the variety quite distinct from all others of its class. From Mr. AMOS PERRY, Enfield.

Tulip Gorgeous (Darwin).—A handsome Tulip of the largest size: the colour, as seen under canvas, is bronzy-red, with a yellow and clouded base. From Messrs. ALEX. DICKSON & SONS, Belfast.

Verbena aubletii compacta.—A dwarf-growing variety that is nearly hardy. The plants as shown were not more than 6 inches in height, the leafage being firm and hard. The rose-coloured blossoms are produced freely even in quite small plants. The variety comes true from seeds, and should be of much value for bedding purposes. From Messrs. DOBBIE & CO., Rothesay.

Actinidia chinensis.—This Chinese plant has some resemblance to a species of *Vitis*. The ovate-acuminate leaves are of considerable beauty, especially when very young, for with

the new growths they assume a pleasing reddish tint, which passes later into a handsome velvety-green. The foliage is densely hairy, and it is to these that the young leaves owe their beauty in the young state, for they are then reddish. For covering a pergola or trellis work, or training up pillars and walls, it is especially desirable. Shown by Messrs. JAMES VEITCH & SONS, LTD.

Asalea Mme. Anthony Koster (*Siollis x Sinensis*).—This variety owes its principal distinctive feature to a shade of pink in the wing or side petals. The general colour is yellow, and the pink colouring seen on the yellow ground gives a charming shade, which we may describe as orange-pink. The flower truss is well formed, and is of very attractive appearance. The plant was shown as a standard by Messrs. R. & G. CUTBERT, Highgate.

Carnation Marmion.—This at first sight has the appearance of a variety of *Souvenir de la Malmaison*, but it belongs to the winter-flowering section, and was raised from Mrs. Lawson x *Prosperity*. In habit also the plant resembles the "Malmaison" type, being exceedingly strong of growth, and with large, very much curled foliage. It belongs to the multi-coloured or "fancy" section, being bright cherry-red, margined and striped with white. The flowers are exceedingly large. Shown by Mr. H. BURNETT, Guernsey.

Begonia Mrs. J. C. Gwillim.—Of the tuberous-rooting section, and in colour a pleasing salmon-rose. The flower is large, and possesses a charming Rose-shaped centre. Shown by Mr. A. L. Gwillim, New Eltham.

Begonia Rhoda Pope.—The flower of this variety is a delicate shade of pink, merging to almost white in the centre. It has the *Camellia* form, and is altogether most handsome.

Begonia Wm. Marshall.—A variety of the richest scarlet, the large, full petals being pleasingly crenated. The flower is of the "rosette" form.

Begonia Lady Cromer.—Another flower of the "rosette" type, and having very broad petals of a salmon-rose shade. The flowers are large and broadly crenated.

The above three *Begonias* were shown by Messrs. T. S. WARE, LTD., Feltham.

Rose Dr. William Gordon.—A pink variety, figured and described in our issue for August 25, 1906, p. 142. Shown by Messrs. W. PAUL & SON, Waltham Cross.

Caladium Thomas Tomlinson.—A variety of medium-sized foliage. The leaves are distinctly sagittate in shape, and in colouring are most beautiful. The centre of the lamina is of a rich red colour and the margin is green, the intermediate area being splashed with the two colours. Shown by Messrs. JAMES VEITCH & SONS, LTD., Chelsea.

FRUIT TREES.

The only group of trees of a distinctive kind was that sent by Messrs. T. RIVERS & SON, of Sawbridgeworth, and placed in the large tent. It comprised 30 trees of both standard and pyramidal form in 10-inch and 12-inch pots, the principal fruits so presented being *Nectarines*, *Early Rivers*, and *Cardinal*. Each of the trees carried from 12 to 20 ripe and richly-coloured fruits. *Peach Peregrine* was also included, as were *Cherries May Duke*, *Early Rivers*, and *Elton*. A prominent feature was a basket of 18 fine fruits of *Early Rivers Nectarine*.

A striking collection, chiefly of *Cherries*, came from Gunnersbury House, sent by LEOPOLD DE ROTHSCHILD, Esq. (gr. Mr. J. Hudson). Three heavily fruited trees of Governor Wood, May Duke and *Early Rivers*, in pots, formed a background, these being fronted by numerous baskets, 17 of which contained selected *Cherries*, each basket containing from 130 to 150 ripe fruits. There were 10 varieties, as follow:—*Blacks*: *Beurré de Schrecken*, *Early Rivers*, and *Guigne d'Annonay*. *Reds*: *Empress Eugénie* and *May Duke*. *Whites*: *Early Bigarreau*, *Governor Wood*, *Reine Hortense* (very fine), *Elton*, and *Belle d'Orléans*. In addition, there were baskets containing very fine fruits of *Early Rivers Nectarine* and *Early Rivers Plum*. The whole of this really fine collection was gathered in one house at Gunnersbury that measured 32 feet by 18 feet only.

COLLECTIONS OF FRUIT.

From Lord ALDENHAM, Aldenham House, Elstree (gr. Mr. E. Beckett), came a collection of 20 Melons; the fruits were all finely finished and richly perfumed. Amongst the varieties were Sutton's Scarlet, Emerald Gem, Royal Favourite, Hero of Lockinge, Ringleader, and others. Being generally elevated in dishes on stands, and pleasingly dressed with foliage, the group was in excellent taste.

From Messrs. G. BUNYARD & Co., Maidstone, came a wonderfully well-preserved collection of Apples and Pears, there being of the former some 80 dishes or baskets. The varieties of Pears shown were Uvedale's St. Germain, Catillac, and Belle des Arbres. The Apples seemed to be in all cases wonderfully sound and firm. How far, if tasted, the best would compare with Colonial Apples just now, no proof was afforded. Very fine amongst the varieties were Calville des Femmes, Prince Alfred, Annie Elizabeth, Lord Derby, Bramley's Seedling, Belle du Bois, Wagener, Barnack Beauty, King of Tomkins County, Ontario, Bow Hill, Beauty of Kent, &c. Rarely has a better preserved collection of home-grown Apples been seen at the end of May.

Messrs. T. LAXTON & SONS, Bedford, had a large group of plants of their very fine Strawberry Bedford Champion, in pots, some 60 in all, and superbly fruited. With these were also four large baskets of picked fruit, each one contained 60, all very fine and richly-coloured. The fruits are rounded and of a bright scarlet hue.

Messrs. J. & F. CHATFIELD, Southwick, Sussex, had plants in pots of Strawberry Royal Sovereign, also specially fine, picked fruit in baskets and dishes.

VEGETABLES.

A very excellent collection of these was staged from the gardens of the UNIVERSITY COLLEGE, Reading (Mr. C. Foster, Instructor). The samples were mostly in boxes or baskets, and included Tomatos Eclipse, Sunrise, Winter Beauty, Satisfaction, Sunbeam, and others; Carrots Early Gem and Champion Scarlet Horn; Peas Early Giant, Ideal, and Little Marvel; Potatos Ringleader, May Queen, and Duke of York; Cauliflowers First Crop and Magnum Bonum. There were also Cucumbers, Vegetable Marrows, Lettuces, Cabbages, Asparagus (a superb sample); a large free-rooted plant and stems of Sutton's Perfection Asparagus, showing robustness; also a few Melons and Royal Sovereign Strawberries.

From the STUDLEY CASTLE COLLEGE GARDENS (Miss Faithful, Warden), was sent a collection of Red Currant, Tomatos, in pots, and fronting them Broccoli, Cauliflowers, Tomatos, Cucumbers (rather old), Potatos, Asparagus, Marrows, Carrots, dwarf French Beans, and Lettuces. The Broccoli heads were unduly large.

Large bundles of Giant Asparagus, each one containing 100 heads, were sent respectively by Mr. R. STEPHENSON, Burwell, Cambridgeshire, and Mr. A. J. HAWOOD, of Colchester, both samples displaying high-class culture.

Mr. HOBDAV, Romford, had numerous stems 4 feet in length of his new Rhubarb known as Hobday's Giant.

Messrs. SUTTON & SONS, Reading, had a singularly interesting collection of plants in pots of various Potato species, and seedlings from them. The strongest plants were those of Solanum Commersoni, having purple flowers, from Uruguay. Then came S. tuberosum, with flowers deeper in colour, and taller plants of S. maglia, from Kew-grown tubers. S. maglia has white flowers, and S. verrucosum is dark purple; also seedlings from a variety of Labergerie's, and from Blue Giant, showing the ordinary leaf variations found in commercial seedlings. Of tubers in dishes were large ones of the two varieties just named, old and new ones, grown in frames; very excellent samples of Epicure, Up-to-Date, Sir J. Llewellyn, Early Puritan, Abundance, Gladiator, May Queen, Windsor Castle, Satisfaction, Superlative, Reliance, and Ninetyfold among white tubers; and Edgcote Purple, Early Rose, The Dean, King Edward, Lord Tennyson, and Purple Eye, among coloured varieties. The collection included 45 dishes and varieties.

There remain for mention two very extensive and remarkable collections of vegetables, each occupying a table run of 35 feet, and presented

by growers who, without being in any sense rivals, certainly rank amongst the foremost vegetable exhibitors of the day. These were Mr. E. Beckett, gr. to Lord ALDENHAM, Elstree, and Mr. J. Gibson, gr. to the Duke of PORTLAND, Welbeck Abbey, Worksop. Mr. BECKETT staged about 110 dishes and Mr. GIBSON 135 dishes, this collection being perhaps rather too densely packed. Mr. Beckett had his dishes more thinly displayed, and included as a background stems of Victoria and the Sutton Rhubarb; Celeries Solid White, Dwarf Gem, Superb Pink, and Standard Bearer; Broccoli Latest of All, Late Queen, and Satisfaction; also Seakale Beet, Seakale, bundles of Asparagus, Lettuces, and Cabbages; and on the table, Cauliflowers Magnum Bonum and Early Forcing; Cucumbers Matchless, Peerless, Al, Every Day, Satisfaction, and Delicacy; Tomatos Winter Beauty, Eclipse, Peach-bloom, Sunbeam, Golden Perfection, Satisfaction, Best of All, and Al; Potatos Ashleaf, Sir J. Llewellyn, Crimson Beauty, Duke of York, May Queen, Windsor Castle, and King Edward; Peas Early Giant, Duke of Albany, Continuity, Green Gem, and Gradus. There were also numerous dishes of dwarf French and Golden Butter Beans, Vegetable Marrows, Radishes, and many other kinds.

Mr. J. GIBSON had clusters of Cauliflowers White Queen, Purity, Early London, and Magnum Bonum; Broccoli Pearl, Satisfaction, Standwell, Latest of All, and Late Queen; Cucumbers Epicure, Prizewinner, Al, Perfection, Lord Roberts, Peerless, Matchless, and Delicacy, in all 14 dishes; Cabbages Tender and True, Flower of Spring, and April; Rhubarb The Sutton and Royal Albert (3 feet long); Lettuces Commodore Nutt, Golden Ball, Ideal, Marvel, and Supreme; Tomatos Al, Eclipse, Polegate, Satisfaction, Best of All, Prince of Wales, Yellow Dessert, Winter Beauty, The Grape, and others; Potatos Satisfaction, Sharpe's Victor, Reading Russett, May Queen, Superlative, Gladiator, and Windsor Castle; Carrots Early Gem, Early Nantes, and Favourite; Peas Green Gem, World's Record, Duke of Albany, Early Giant, Superlative, Alderman, and Centenary, these latter being wonderfully fine. There were many other kinds of vegetables, making up a wonderful collection.

A fine exhibit by Messrs. JAS. CARTER & Co., High Holborn, consisted of their Tomato Sunrise. The fruits were seen in great clusters on tall sticks 5 feet in height forming a tripod, and some heavily fruited plants in pots.

[For the list of Medals, Cups, &c., awarded by the Council, see p. xiii.]

KEW GUILD.

MAY 27.—The annual meeting and dinner of past and present Kew men was held at the Holborn Restaurant on the above date. The annual meeting was presided over by the President, Mr. W. Watson, A.L.S., curator of the gardens, and it was more largely attended than on former occasions. The report of the Committee for the past year showed that the total assets of the Guild are now more than £300; the sum of £50 was invested in stock, and a balance of more than £10 remains as the result of the year's saving. The *Journal* is in greater demand than ever, and nearly 700 copies were distributed in 1906.

The meeting decided that a new president should be elected annually, and that the chairman of the annual dinner should act in that capacity until the next annual gathering. A letter from a member in Egypt was read by the Secretary, in which the writer advocated some change of policy, whereby the interests of those members who were practical gardeners, and especially of those in Colonial service, should be championed by the Guild. After discussion, it was decided that the committee should be empowered to consider the question, and, if necessary, to co-opt other members to assist in the deliberations.

A statement recently made in the House of Commons to the effect that the wages paid to the young gardeners at Kew were low partly because they were only apprentices, was the subject of a discussion, and evoked much indignation. The following resolution was unanimously adopted:—

"That this meeting of the Kew Guild, composed of past and present gardeners and others employed at Kew, protests against the statement made officially by

Sir E. Strachey in the House of Commons on May 23, that 'the men employed at Kew are not gardeners but apprentices.' They are men of the average age of 23, who have had at least five years' professional training before entering Kew as journeyman gardeners, and their duties at Kew are the care and cultivation of the living collections of plants. They work from 6 a.m. to 6 p.m. in summer, and from daylight to dark in winter; they also attend certain lectures in their own time at night after their day's work is done. They are certainly as much entitled to be called gardeners as any other men of the same age and training, and it is a misrepresentation of the facts to describe them as apprentices."

The dinner, presided over by Mr. George Massee, was as largely attended as ever, and afforded pleasant opportunities for reminiscences between old friends, many of whom had assembled from distant quarters of the empire.

ROYAL GARDENERS' ORPHAN FUND.

MAY 23.—The 19th annual festival dinner of the supporters and friends of this institution was held on this date at De Keyser's Royal Hotel, Victoria Embankment, E.C., under the presidency of the Right Hon. the Lord Mayor, Alderman Sir William P. Treloar, and he was supported by Sheriff W. H. Dunn, Messrs. Harry J. Veitch, Edward Sherwood (treasurer), Leonard Sutton, W. A. Bilney, and a company numbering 150. The function proved a great success, and a sum of more than £1,000 was raised in aid of the funds of this deserving gardening charity at and in consequence of the dinner. No better President for such a meeting could be found than London's present Chief Magistrate, whose sympathies with unfortunate children are well known. The tables were lavishly decorated with choice flowers, the gifts of friends and supporters of the charity, and decorative plants adorned the approaches about the magnificent room in which the function was held, the scene eliciting from the Lord Mayor the remark, "It is the most beautiful show I have ever seen."

When the usual loyal toasts had been honoured, the Chairman proposed the toast of "The Royal Gardeners' Orphan Fund." He stated the duty of caring for orphans, but pointed out that it did not need any speech of his to press the claims of the charity upon his hearers, and he called upon Edward Sherwood, Esq., the hon. treasurer, to furnish some particulars of the charity.

Mr. Sherwood stated that last year's income was a record one, but the need for increased support is urgent, for, whereas, in 1905, 13 beneficiaries were added to the Fund, last year 19 were added, and the institution now maintaining a total of 122 orphans, in addition to aiding others with temporary relief. They had collected a grand total of £34,000 since the Fund was inaugurated, and had invested £11,000, but this latter sum was not sufficient to discharge their liability, as the average number of years the children already on the Fund will receive benefit is 9½, and this will absorb a sum of £14,000. The annual subscription list is very small; indeed the amount is not more than £300, but he was glad to know that every penny received at the dinner or elsewhere is applied to the orphans, the returns from the invested funds being sufficient to pay all the working expenses.

The next toast, that of "Gardeners and Gardening," was proposed by Sir Albert Rollit in a speech which showed Sir Albert's wide and varied knowledge. Having a knowledge of gardens in France, Germany, Florida, Damascus, and elsewhere, he proclaimed England the garden of the world, London a garden city, and the Thames the garden river of the universe. Not only our gardens, but our flower shows were the best in the world, and the British gardener was a person who specially claims our consideration.

Mr. W. A. Bilney replied, and declared gardeners generally to be honest, sober men, whom employers should treat as fellow men, for they will find them guides and philosophers. He hoped no union of gardeners would be formed during his lifetime. It was disagreeable to contemplate 13 or 15 gardeners on an estate being ordered "out" by a strike committee, the result of which would be that the plants would languish and die. If ever this were to take place it would kill horticulture in this country.

The next toast was "The Visitors," proposed by Mr. John Assbee, and responded to by Sheriff W. H. Dunn, who, being a member of the Council of the Royal Botanic Society, claimed that

that Society is doing much for the interests of horticulture. Mr. H. B. May proposed the health of the Chairman, and said that Sir William Treloar would be best known to posterity as the "Children's" Alderman. The present was the first occasion on which the festival dinner was presided over by the Chief Magistrate for London. "The Press" was proposed by Mr. W. Poupert, and suitably responded to by Mr. John Collingridge.

The Secretary announced a sum of over £1,000 as the result of the gathering. Among the principal subscribers and collectors were those following:—Messrs. Sutton and Sons, £100; Messrs. Hurst and Son, £52 10s.; Mr. Edward Sherwood, £30; Messrs. N. M. Rothschild and Sons, £26 5s.; the Lord Mayor, £10 10s.; Mr. Leonard Sutton, £10 10s.; Mr. George Reynolds, £44 13s. (including £10 10s. from Mr. Leopold de Rothschild and £10 10s. from Mr. Anthony Waterer); Mr. George H. Cuthbert, £40 2s. 6d.; Mr. J. F. McLeod, £32 10s.; Mr. James L. Kinnell, £27 7s.; Mr. W. A. Garaway, £18 13s. 2d.; Mr. R. Hooper Pearson, £15 15s. (including 5 guineas from the Gardeners' Chronicle, Ltd); Mr. Whitpain Nutting, £12 1s. 6d.; Mr. G. L. Caselton, £11; Mr. P. de Keyser, £10 10s.; Mr. J. C. Eno, £10 10s.; Mr. H. F. Tiarks, £10 10s.; Mr. T. W. Sanders, £10 10s.; Messrs. James Veitch and Sons, Ltd., £10 10s.; Mr. P. C. M. Veitch, £11 11s. 6d.; Messrs. Barr and Sons, £10; and Covent Garden friends, per Mr. John Assbee, £170.

It may be added that the floral arrangements were carried out by Mrs. Ritz, and among the firms who contributed flowers or plants were Messrs. Jas. Veitch and Sons, F. Sander and Sons, Barr and Sons, T. Rochford and Sons, A. Smith, — Crouch, Otto Heihle, Engelmann, &c.

Obituary.

E. RANGER JOHNSON.—The many horticultural friends of this widely-known and much-respected journalist will regret to learn of his death on May 16, at Eardley Crescent, Earl's Court, S.W., in his 70th year. Mr. Ranger Johnson was one of the oldest members of the editorial staff of the *Morning Post*, with which paper he became associated in 1881. He came to London from the West of England early in life, and brought with him a love of floriculture in particular and an enthusiasm for horticulture in general, which remained with him through life. For many years he was a regular attendant at the principal metropolitan flower shows, and had few equals on the daily Press as a writer on subjects connected with gardening.

ANSWERS TO CORRESPONDENTS.

* * * The Editor will be glad to receive, for consideration, large photographs of horticultural subjects, suitable for forming Supplementary Illustrations to this Journal.

BEANS: J. R. The blackened foliage of the Beans is not associated with any organic disease. It may possibly be caused by rapid atmospheric changes. The plants themselves afford no solution of the mystery.

CARNATION "YELLOWS": F. A. This yellowing of the foliage of Carnations is still somewhat of a puzzle, because no organisms can be found to account for it. It has sometimes been called Bacteriosis, and cultivators have been recommended to keep the foliage dry and also to syringe with diluted Condy's Fluid, but we have heard of no successful treatment.

CARPENTER AND DESIGNER: A. M. Your advertisement will answer most of your questions better than we can. Not only is a knowledge of geometry necessary in landscape gardening, but an intimate acquaintance with the habits of hardy plants of all kinds, their suitability for certain soils and positions, colour of their flowers, &c., is equally important. If you pursue a knowledge of the art of geometry, it will be very useful in your own trade, and

especially useful in the theory of building construction, which is taught at most polytechnics and art centres. It would probably pay you best to stick to your own "last."

CURRENT LEAF BLISTER: E. G. W. The blisters on the leaves of your Black Currant appear to be caused by a minute insect. If you will send us samples of the diseased fruit, we will examine them.

FRUIT CULTURE FOR PROFIT: M. J. F. You should certainly obtain some knowledge of the business before you commence on your own responsibility. The capital you mention is sufficient to make a start upon, but you must remember that you will have to compete with men of experience and wide knowledge of the subject. Make enquiries in such fruit-growing centres as Evesham, Worthing, Swanley, &c., and endeavour to obtain work for a year or more in one of the most famous firms. You would probably meet with better success in the fruit-growing colonies. See also reply to *Sussex Amateur* on p. 340.

GRAPES DISEASED: H. C. The berries are affected with the "spot" disease, *Glœosporium ampelophagum*. Cut out and burn the diseased fruits and spray the healthy bunches with liver of sulphur, using half-an-ounce to one gallon of water. This chemical will turn paint a black colour, therefore be careful of the woodwork in the vinery.

INSECT ON ORCHID: W. B. The specimen you send is a clay-coloured Weevil, and we certainly suspect Weevils are the cause of the injury, for they are amongst the worst of garden pests. Trap them with pieces of some vegetable root, such as Carrot or Potato, and hunt them when it is dark, at which time they feed.

MELON WILT: J. P. The Melon plants appear to be attacked by some species of Anthracnose (*Glœosporium*), but no pustules and no spores are developed, so that it is impossible to identify the species. Syringe the plants with a weak solution of the Bordeaux mixture, having first removed the spotted leaves. It is, however, doubtful whether the affected plants can recover, and they are a danger to healthy plants in their vicinity.

MOSS ON LAWN: T. R. C. Rake off the Moss and apply some nitrogenous manure in order to encourage the growth of the Grasses. The presence of Moss is generally the result of a badly drained turf or a shaded situation. If the subsoil is limestone, you did wrong to apply calcareous matter as a top-dressing.

NAMES OF FLOWERS, FRUITS AND PLANTS.—We are anxious to oblige correspondents as far as we consistently can, but they must bear in mind that it is no part of our duty to our subscribers to name either flowers or fruits. Such work entails considerable outlay, both of time and money, and cannot be allowed to disorganise the preparations for the weekly issue, or to encroach upon time required for the conduct of the paper. Correspondents should never send more than six plants or fruits at one time: they should be very careful to pack and label them properly, to give every information as to the county the fruits are grown in, and to send ripe, or nearly ripe, specimens which show the character of the variety. By neglecting these precautions correspondents add greatly to our labour, and run the risk of delay and incorrect determinations. Correspondents not answered in one issue are requested to be so good as to consult the following numbers.

PLANTS: J. F. *Rubus nutkana*.—F. S. 1, *Rubus spectabilis*; 2, *Lonicera tatarica* var. *punicea*; 3, *Erica mediterranea*; 4, *Hydrangea Hortensis* var. *Mariesii*; 5, *Hacquetia Epipactis*.—*Subscriber*. *Cornus mas*, variegated form.—*Interested*. *Pyrus Aria*.—F. E. G. *Akebia quinata*.—L. G. P. 1, *Lycaste aromatica*; 2, L. Deppel.—*Norwood*. (The package arrived without a letter.) 1, *Staphylea colchica*; 2, *Scilla campanulata*.—G. T. W. 1, *Odontoglossum triumphans*, not a good variety; 2, *O. Hunnewellianum*; 3, *O. Pescatorei* (nobile).—A. K. 1, *Cypripedium villosum*; 2, *Odontoglossum citrosum*; 3, *Rivinia humilis* (Rouge plant); 4, *Celsia cretica*.—C. B. G. 1, *Orchis Morio*; 2, *Gymnadenia conopsea*.—U. N. A. 1, *Tainia barbata*; 2, *Pholidota chinensis*; 3, *Coelogyne ochracea*; 4, *C. odoratissima*; 5, *Pholidota imbricata*; 6, *Dendrobium dixanthum*.—J. E. S. *Epidendrum osmanthum* syn. *E. Capartianum*.—J. F. *Rose L'Idéale*.—J. S.

1, *Billbergia Regina*; 2, *Mamillaria* sp.; 3, *Cereus speciosissimus*; 4, *Mamillaria tenuis*.—E. F. 1, *Stauntonia hexaphylla*; 2, *Olearia stellulata*; 3, *Ceanothus azureus*; 4, *Polemonium coeruleum* (fine variety); 5, *Helianthemum vulgare* var.; 6, *Silene pendula*.—*Arund*. 1, *Primula mollis*; 2, *Asparagus Sprengeri*; 3, *Akebia quinata*.—A. M. 2, *Geitonoplesium cymosum*, a native of Australia.—E. W. 1, *Kerria japonica* double variety; 2, *Lonicera tatarica*; 3, *Phlox subulata* var. *Vivia*.—A. B. 1, *Phlox canadensis*; 2, *Jasminum Sambac*.—A. B. C. *Crassula hybrid* (*Coccinea* x *jasminoides*).—J. McG. 1, *Cyrtomium falcatum*, badly infested with thrips; 2, *Gymnogramma japonica* variegata.—H. P. A show *Pelargonium*, perhaps Emperor of India.—*Cov*. 1, *Kerria japonica*; 2, *Gaultheria Shallon*; 3, *Ruscus hypophyllum*; 4, *Lonicera japonica aurea reticulata*; 5, *Saxifraga granulata*; 6, *Cardamine pratense*.—P. G. T. 1, *Dendrobium Falconeri*; 2, *Dendrobium clavatum*.—H. A. 1, *Phlox frondosa*; 2, *P. subulata* var. *Nelsoni*; 3, *P. G. F. Wilson* x; 4, *P. subulata* variety; 5, *P. s. var. Vivid*; 6, *P. s. var. The Bride*; 7, *P. s. variety*; 8, *Saxifraga granulata* double form; 9, *Primula farinosa*; 10, *Gypsophila cerastioides*; 11, *Phlox amœna*; 12, *P. subulata* var. *atropurpurea*; 13, *Phlox stellaris*. You send more than six; a small contribution to the Royal Gardeners' Orphan Fund box would be appropriate.

PANSIES: T. G. The pest injuring the roots of the Pansies is one of the millipedes, *Julus guttatus*, sometimes known also as the "false wireworm," though it has no relation to the true wireworm. These pests are general feeders, for they attack both living and dead vegetable matter, and are often distributed in manure and leaf-mould. They may be collected in numbers by placing pieces of hollowed-out Potatoes or Mangolds just below the surface of the ground near the infected plants. The bait should be examined frequently and the pests removed and destroyed. Soot and water with a very little nitrate of soda added is said to drive them away, though it may be doubted if this application has any other effect than that of stimulating the growth of the plants.

ROSE MILDEW: *Constant Reader*. The foliage is badly affected with the common Rose mildew. Dust the plants freely with flowers of sulphur, and in the case of those growing in a heated structure, smear some of the sulphur made in the form of a paste upon the water pipes when they are in a heated condition.

SOIL FROM GREEN: F. W. G. The soil has all the appearance of having been over-fed with strong nitrogenous manures. It has a fungus-like smell and is permeated with mycelium growth. There is a small proportion of lime present, but not enough for this character of soil; a dressing should be given of say—1 ton per acre of lime ground finely (not slacked) which can be purchased in bags. The lime, however, must not be received until you are ready to sow it, for if stored it will burst the bags. Let the lime be sown broadcast in the autumn or early in winter as soon as you can spare the ground from play, because it cannot be afterwards used until the lime has been well washed in. If you cannot spare all the ground at once, treat portions only at one time. The cinders have had nothing to do with the failure of the grass. Applications of sand are not required, but some finely-sifted mould to which may be added a quantity of decomposed horse-droppings would be beneficial. The mould and horse-droppings should be applied after the lime has been washed in. Early in the spring of next year sow some fresh grass seeds on the bare places.

VINE LEAVES: F. W. J. The warty excrescences on your vine leaves are the result of a too close and moisture-saturated atmosphere in the vinery.

ROOT-ROT FUNGUS.

ATTENTION is now being directed in the United States to a disease which attacks indiscriminately a great variety of cultivated plants. It was first observed in this country by Berkeley and Broome in 1850, as attacking the stems of Peas, and also plants of Nemophila. Then it was described and named *Torula basicola* (B. and Br.), under which name it appears in *Cooke's Handbook* (p. 477). The fungus is described as black, and effused, the creeping threads here and there rising from the general mass, and giving off fascicles of short fertile branches, consisting of from five to seven joints, which at length separate as conidia; since which time it has apparently not been observed as a pest in the United Kingdom. In 1876 it was recorded in Germany, on the roots of a species of *Senecio*, and later, on a number of leguminous plants. Subsequently it occurred in the United States on the roots of Violets, threatening them seriously in 1891; but in 1906 it was found inflicting serious injury in the Tobacco beds of the Connecticut Valley, hav-

ing already proved a serious pest in Cuba, soon spreading to an alarming extent over the Tobacco districts of America. So far as present information extends, it has been found on *Nemophila* and Peas in England; on *Aralia*, and *Begonia*, in Ohio and Germany; on Horseradish in Russia; on *Cyclamen* in Germany, as well as on Lupins; on Tobacco in Italy and United States, as well as Cuba; on *Onobrychis* in Germany, as well as *Trigonella*; on *Senecio* in Germany, and on *Viola odorata* in North America.

At first it was regarded as simply a saprophyte, like so many of its congeners. Zopf considered it a true parasite, but Sorauer concluded that it had a saprophytic as well as a parasitic existence, since he found it on leaf moulds, and stated that it might occur on soil, at times, without doing injury to the roots of plants. Sorauer and Aderhold agree that it becomes an aggressive parasite, under certain favourable conditions.

Later investigations have resulted in the removal of this fungus from the genus *Torula*, so that now it is called *Thielavia*

FIG. 158.—ROOT-ROT FUNGUS: *ThIELAVIA BASICOLA*.

A mycelium; B, endosporeous threads; C, endospores; D, chlamydospores; E, ascospores.

basicola, having previously been described as *Helminthosporium fragile* in 1876, and as *Cladosporium fragile* in 1886.

The vegetative portion of the fungus consists of hyaline, septate, branched threads (fig. 153, a), which penetrate the tissues of the host plants. The external portion of this mycelium soon becomes slightly tinted, and eventually gives rise to three kinds of reproductive bodies, with suggestions of a fourth kind, or spermatia, but this latter is still doubtful.

I.—Endospores formed in a special thread of the mycelium (fig. 153, b). The endospore case is terminal on the threads of the mycelium, with a slightly swollen base, several short basal cells, and a long, tapering terminal cell. The endospores are gradually formed in the apex of this terminal cell, and are pushed out at the ruptured end. These are hyaline, thin-walled, oblong, or linear, and vary in size from 10 to 25 mm. in length and 4 to 5 mm. in breadth (fig. 153, c).

II.—Chlamydospores are thicker-walled, dark reddish-brown bodies, which rarely germinate at once, but are of the nature of

resting spores, and are adapted for carrying the fungus over unfavourable periods. They are borne on the same mycelium as the endospores, and often as side branches. They may be considered as compound spores, consisting of one, two or three sterile basal cells, and from one to seven fertile cells. The basal cells are hyaline or slightly tinted, while the fertile cells are dark reddish-brown, thick-walled, and ultimately separating into flattened individual cells. As a whole, the compound spores are oblong, with the terminal cell rounded, the sterile basal cells tapering downwards. The length of these compound spores, without the sterile base, is from 20 to 50 mm. and their width from 10 to 15 mm. (fig. 153, d).

III.—Ascospores.—These are dark-coloured, single-celled, lenticular spores, about 12 by 5 mm. and are produced in asci or hyaline sacs. Each ascus contains eight ascospores, and, in turn, these asci are enclosed in a spherical receptacle called the perithecium. The perithecia and asci appear to be very fragile and temporary, so that the ascospores may be found towards the end of the season commonly shed out on the older Tobacco roots (fig. 153, e).

The root-rot fungus, as studied in connection with Tobacco crops, develops almost entirely under ground, attacking the roots and the underground part of the stem. The tap root, prominent in young plants, is often rotted off close to the stem, or there is a general rotting of the tap and secondary roots.

According to observation, a very weak strength of formalin (about 1 to 1,500) sprinkled several times on the plants in the infected beds did not give very favourable results.

I am indebted for most of the details of this communication to the report of the Connecticut Agricultural Experiment Station for 1906, part V., which concludes with an enumeration of the literature, amounting to twenty-four separate articles, and communications, on this special pest. M. C. Cooke.

LILIES AND THEIR CHARACTERISTICS.

THE variable conditions which have prevailed during the past spring, however adversely they have affected other plants, seem to have been extremely favourable to the growth of Oriental and Occidental Lilies. There is nothing more interesting in the practise of horticulture than to watch the development of such invaluable introductions as these Lilies, which have come to us from the remote regions of the East and of the West. Not even the much-prized *Magnolias* of America and Japan (of which the loveliest, *M. Watsoni*, flowers exquisitely here), have proved of greater value for border and shrubbery ornamentation. This affirmation is especially expressive of *Lilium auratum*, of which the older forms are assuredly the best for decorative purposes, for, such varieties as *L. auratum platyphyllum*, however impressive in the dimensions of their flowers, are lacking in those charming chocolate spots which constitute half the beauty of this justly celebrated Lily of Japan. Perhaps the finest of all the forms of *L. auratum*—at least, in

the direction of picturesque colouring—is *Lilium auratum rubro-vittatum*, which can easily be recognised even from a long distance, by reason of its radiant loveliness. It is, however, according to my experience, exceedingly evanescent, having been in my own garden "a dream of beauty" too bright to last. It would almost require to be treated as an annual, and planted every year, if grown in a cold and adhesive soil. I used to imagine that *Lilium Washingtonianum* was reliable, but after flowering gracefully for a few years in my garden, it has entirely died out, the cold rains of winter and of early spring having ultimately proved too much for its tender constitution. This is one of the loveliest of American Lilies; it is a native of

ing year. I had, I confess, some difficulty at first with *Lilium pardalinum*, but after the second season of planting it rapidly developed and redeemed its reputation. Its finest derivative, *Lilium × Burbankii*, multiplies its bulbs with astonishing profusion, and flowers well.

I have never seen the fairest of Levantine Lilies—*Lilium candidum*—to greater advantage than in Logan Gardens in this picturesque parish, where, grown extensively amongst pink and crimson Roses, it has a memorably artistic effect. *Lilium giganteum*, cultivated in richly fertilised borders, is also very successful in these gardens, and frequently reaches a height of more than 10 feet before displaying its great masses of ivory-white, violet-streaked, intensely-frag-

ANSELLIA GIGANTEA.

We are again indebted to Sir Chas. W. Strickland, Bart., for a photograph of an interesting Orchid, and from which the accompanying illustration of *Ansellia gigantea* was prepared. It represents a specimen that flowered in the gardens of A. J. Cholmondley, Esq., at Newton, near Malton, Yorks., who originally brought the plant from the neighbourhood of the Crocodile River, Africa. The plant developed 13 spikes of flowers, each spike being about one foot in length, and carrying from 45 to 50 blooms of a pale yellow colour spotted with red-brown.

Ansellia africana, which is taller than the species here illustrated, is the oldest and best known in gardens, and in consequence of the general resemblance of the different members

FIG. 154.—ANSELLIA GIGANTEA: COLOUR OF FLOWERS PALE YELLOW, SPOTTED WITH BROWN.

California. The refined, white flower is faintly suffused with spots of pink, and it exhales a most fascinating fragrance, reminding one of the odour of the honeysuckle.

Among the noblest of all Lilies, and, when firmly established, one of the most reliable, is *Lilium monadelphum Szovitzianum*, which here attains to almost unique dimensions. This is an Eastern species, which is easily distinguished, not only by its unusual strength and stature, but also by its perfectly formed and charming lemon coloured flowers. The long buds, before expansion, are supremely beautiful. *Lilium pardalinum*—the Californian Panther Lily—while not quite so attractive, is highly distinctive, and though it is some years before it becomes well established, unless grown in a fibrous, peaty soil, it eventually succeeds, and afterwards increases in vigour each succeed-

rant flowers. It is to be regretted that this great Indian Lily requires so many years for the development of its bulbous offsets, for this is doubtless the reason why its planting is restricted. *David R. Williamson.*

VEGETABLES.

CARTER'S FORCING PEA.

I sowed seeds of this Pea in the third week in February, in 7½-inch pots in a compost of loam, and manure from a spent Mushroom-bed, planting five or six Peas in each pot. I put them in the Peach-house, which had no artificial heat, and was able to pick nice-sized Peas on May 7. The height of the plants is only about 15 inches, therefore if a few twigs are placed to them whilst growing, these are all the support they require. *T. W. Birkinshaw, Hatley Park Gardens, Sandy, Beds.*

of the genus they are often found bearing that name in gardens.

But even for garden purposes the genus gives great variety and beauty, *A. africana*, *A. confusa*, and others which inhabit the Western African region being well separated from the more eastern *A. gigantea*, which, as it spreads to Natal and other cooler situations, in itself gives great variety, the almost wholly yellow form being so different in colour from the type as to cause the name *Ansellia lutea* to be given to it.

The Ansellias are easy to cultivate in a warm greenhouse or plant stove. They require an abundance of water during their actively growing period, and it much prolongs the duration of the flowers if they are removed to a warm, airy conservatory at the time the plants are in bloom. After flowering, a restricted supply of water should be given until growth commences again. *J. O'B.*

THE GENUS ENKIANTHUS.

(Concluded from page 344.)

E. CHINENSIS.—A much branched bush or small tree, 2-6 metres high. Leaves shortly stalked, very variable in size and form, but usually elliptic or obovate-elliptic, narrowed to the base and apex, serrulate; always glabrous and pale-green below. Flowers in pendulous, thyrsoid, or sub-umbellate racemes 6-7 cent. long. Pedicels 1½-2 cent. long, slender, glabrous. Corolla widely campanulate, yellowish-orange striped with red; corolla-lobes variable in size and form, usually dark red, sometimes slightly reflexed. Fruit similar to that of *E. himalaicus*.

This species is possibly nothing but a geographical form of *E. himalaicus*, but its entirely glabrous leaves and pedicels readily distinguish it. As a rule, the flowers of *E. chinensis* are larger, more deeply cleft, the style longer, the stamens, ovary, and style very much less setulose than in those of *E. himalaicus*; but all these characters vary, and the only constant one is the entirely glabrous leaves and pedicels. The leaves in both species vary in size, form, and degree of serrature.

E. CHINENSIS was first discovered near Tali, in Yunnan, by Delavay, Henry subsequently collected it in Hupeh, and Père Farges in North-east Szechuan. In my wanderings in Hupeh I met with it very frequently in precipitous places from 5,000 to 7,500 feet, but not once did I see it in West Szechuan. As far as my observations go it is to Hupeh what *E. himalaicus* is to West Szechuan. It is equally beautiful when in flower, and its autumn tints are similarly brilliant. Plants were raised in Messrs. Veitch's Coombe Wood Nursery from seeds collected in Hupeh.

E. brachyphyllus is described as differing from *E. chinensis* in having sub-orbicular or rhomboid leaves, erect corolla-lobes and rose-coloured flowers with no red striæ. These distinctions, in view of the variable character of *E. chinensis*, are too slight to separate the species. The late M. Franchet founded his *E. brachyphyllus* on specimens collected by Père Delavay at Outchay, a village midway between Ta-kuan and Chau Tung on the main road from Sui-fu to Yunnan-fu.

E. ROSTHORNII is described as a provisional species standing between *E. chinensis* and *E. brachyphyllus*, with broadly elliptic leaves, which in serrature approximate to those of *E. campanulatus*. Dr. Diels founded this species on a barren leafy shoot collected in September by Baron von Rosthorn, near Nan Chuan, in South Szechuan. Whilst I have seen no specimen of *E. chinensis* with serratures exactly as described for *E. Rosthornii*, I have no doubt but that it is merely a form of this variable species.

B. CHINENSIS, Franchet in Morot Journ. de Bot. ix. (1895) p. 871.

E. himalaicus var *chinensis*, Diels in Engler Jahrb. xxix., p. 508.

E. brachyphyllus, Franchet, l. c.

E. Rosthornii, Diels l. c. p. 509.

E. PAUCIFLORUS, E. H. Wilson, sp. nov. Bush 1-3 metres, much branched; bark dark brown, winged, peeling off in the third and fourth year. Leaves clustered at the ends of shoots, petioled; blade elliptic or obovate, usually narrowed to base 1½-3½ cent. long, 6-15 mm. broad, rounded or obtuse, mucronate, finely serrulate, teeth mucronulate, glabrous, primary and secondary veins brown, prominent, puberulous; petioles 2-5 mm. long, winged in upper part; slightly pubescent. Flowers yellow with few red striæ, solitary or very rarely in pairs; peduncles flattened, recurved, 1 cent. long, slightly hairy; calyx lobes 1-1½ mm., ovate, acute; corolla globularly campanulate, 8-10 mm. broad, somewhat puberulous on both surfaces; lobeshort, usually reflexed; stamens half the length of the corolla; filaments 2-2½ mm. long, dilated at base; anthers 1 mm., horns as long as anthers, divaricate and somewhat recurved, very sparsely setulose; ovary dark coloured, sub-glo-

bosc; style 1 cent. long, glabrous or very finely puberulous; stigma simple. Fruit immature but apparently similar to that of *E. himalaicus*, only smaller.

W. China, Prov. Szechuan, Mt. Wa., 10,000-11,000 feet, Wilson, 8,913!

A very neat species allied to *E. himalaicus*, but readily distinguished from it. The unflowered character is seldom departed from, but two flowers do occasionally arise from the same axis. Native of humus-clad cliffs on the upper part of Mt. Wa. Not in cultivation, and as a garden plant the least valuable of the family.

E. SUBSESSILIS. A much branched shrub, 1-3 metres high, with reddish bark, young shoots hairy. Leaves, shortly stalked, membranous, obovate-elliptic, 2½-3 cent. long, 1-1½ cent. broad, crenulate-serrulate, with a few scattered hairs on both surfaces but more numerous below; petioles hairy. Flowers white in pendulous racemes, 4-5 cent. long; pedicels straight, filiform, 1½-2 cent. long. Calyx-lobes ovate-acuminate, ciliate. Corolla urceolate, about 5 mm. long and broad, lobes short, reflexed. Style very slightly exserted. Fruit globose, 2-2½ mm. long, ribbed, pendulous.

This is one of the least ornamental of the genus; the flowers are small and "the foliage assumes a brilliant red colour in the autumn." In cultivation in the Arnold Arboretum, where it was raised from seeds collected in 1892, in Japan, by Prof. Sargent. It is also in cultivation with M. Maurice L. de Vilmorin, at Les Barres.

E. SUBSESSILIS.—Makino, in Tokyo, Bot. Mag. viii. (1894), 215. Sargent, Trees and Shrubs, part 1, p. 49, fig. xxv.

Enkianthus nikoensis Makino, l. c.

Andromeda subseussilis. Miq., Ann. Mus. Lugd. Bot. i., p. 32 (1863-64).

Andromeda nikoensis, Maxim. Bull. Acad. Sci., St. Petersburg, xxxi., p. 496 (1888).

E. NIPPONICUS.—This species is not represented in the Kew Herbarium, and is probably not in cultivation in this country. Palibini (l. c.) describes it as a small twiggy bush, with the corolla twice the length of the calyx, and the anthers and filaments equal in length. The corolla is campanulate and sharply toothed, as in *E. Meisteria*, indeed, it is very possible that *E. nipponicus* is merely a form of this species.

E. nipponicus is native of the island of Nippon, in the province of Ise, near Kamino-Yama at 5,000 ft.

E. nipponicus, Palib. in Rev. Gen. Enkianthus, ii.—Japan.

E. MEISTERIA.—A much branched shrub 2-3 metres high, with obovate leaves, including petioles, 1-4 cent long, ½-2 cent broad, reddish hairy below. Flowers in pendulous racemes. Corolla campanulate, 4-7 mm. long and broad, fringed, with acuminate teeth. Fruits similar to, but smaller than, those of *E. campanulatus*.

In the type the flowers are white, but there is a variety, *rubens*, in which the flowers are reddish. This species is in cultivation at Kew under the name of *E. cernuus*, and as such it is recorded in the Kew Hand-list of trees and shrubs. Benth and Hooker are cited as authorities for the name, but there is some mistake about this, since these authors never made the combination. The fringed corolla neatly distinguishes this species from all others save *E. nipponicus*. *E. Meisteria* is native of Japan, being apparently rather widely spread, and is known by the vernacular name of "Biniadon." It is a neat and very pretty species, well worth growing. The variety *rubens* is even better than the type.

E. MEISTERIA.—Maximowicz in Melanges Biolog. v. xii., p. 741.

NURSERY NOTES.

ORNAMENTAL AND USEFUL PLANTS AT EXETER.

THAT part of Messrs. R. Veitch and Sons' Exeter nurseries known as the Hoopern Nursery is now being built upon, and a pretty spot is thus lost to the town. A public path ran through it, and it was, to quote a paragraph from a local newspaper, "one of Exeter's greatest charms and most popular walks, being always well-kept and containing many beautiful specimens of the flora of this and other countries." A special feature of this part of the nursery was the large collection of trees of the genera *Prunus* and *Pyrus*; some of these have been removed to the Cleve Nursery at Exwick, and others to the Retreat Nursery at Exminster.

The Royal Nursery, a few minutes' walk from the London and South-Western Railway Station, still remains the depot for all kinds of stove, greenhouse, and herbaceous subjects. The plants seen in late April included a fine batch of *Dimorphotheca Ecklonis*; *Arctotis revoluta*, with its freely-produced orange-yellow flowers; and *Myosotidium nobile*, the Chatham Island Forget-Me-Not, bearing large racemes of blue and white flowers above its glossy leaves. Amongst shrubs suitable for outdoor culture in the south-west of England or in Ireland were seen healthy plants of *Tricuspidaria lanceolata* and *T. dependens*; *Othelia japonica*, a white-flowered species; and *Mimulus* [*Diplacus*] *glutinosus coccineus*, a plant having deep red-coloured flowers, and which has proved hardy in Devon and Cornwall.

Amongst economic plants seen were *Quillaja Saponaria* (Chili soap bark), *Ipomœa purga* (common Jalap), and *Fabiana imbricata* (the Piche of Chili). This last-named plant was first brought to notice in 1886 as a remedy in lumbago, sciatica, and rheumatic affections. Though the plant belongs to the Solonaceæ, its heath-like habit and white flowers give it quite the appearance of a species of *Erica*. *Eucommia ulmoides* is another interesting plant, the bark of which is laden with rubber, which can be readily drawn out in fine silk threads by breaking the bark across. It is a native of China. *Illicium religiosum* is a Japanese tree, and is closely allied to the Star Anise of commerce. *Leuca-dendron argenteum*, well known as the Cape Silver Tree; *Cassia marylandica* (North American Senna); *Drimys Winteri* (Winter's Bark); *Punica Granatum* (Pomegranate); *Spigelia marilandica* (the Indian Pink Root of North America); and *Sanguinaria canadensis* (the Bloodroot or Puccoon of North America) were also noticed. J. R. J., Lymington.

PLANT NOTES.

RHODODENDRON × SESTERIANUM.

ALTHOUGH this hybrid is usually classed as a greenhouse subject, it thrives admirably out of doors in these gardens, and I send you a few flower trusses with these notes. The tree is planted close to a high wall and in a fairly sheltered corner, with a good rooting medium of peat. The flowers remind one of the variety Lady Alice Fitzwilliam, being creamy white and having a very sweet perfume. The foliage is rather small and dark green in colour. Growing in the position mentioned, the plant has a somewhat straggling habit, but a few stakes suffice to keep it symmetrical. The flowers usually open about the end of May, and thus they escape late spring frosts.

SPIRÆA ARGUTA.

FEW plants are more handsome at this time of year than this shrubby *Spiræa*, for its long pendulous shoots are now prettily wreathed with flowers of the purest whiteness. One plant in these gardens opens its flowers quite early in April, and the only difference that can be

noted is that it is not quite so robust as others of the same species. Doubtless this shrub can be rooted by inserting cuttings in early autumn, but the best and quickest method of propagation is by layering the bottom branches, which quickly form roots and soon make good plants. When the flowers have faded most of the old growths should be cut out, some quite to the base, after which robust shoots will appear, and these will furnish flowers next year.

REHMANNIA ANGULATA.

THIS plant has stood out-of-doors the past winter here, and is now (May 25) well in flower. It is planted at the foot of a south wall, against the other side of which is a powerful tubular boiler, which accounts, no doubt, for the plant having survived the rather severe winter. For neighbours it has the old *Jacoea Lily*, *Sprekelia* [*Amaryllis*] *formosissima*, which is now pushing up its flower-spikes, and *Agapanthus umbellatus*, but the foliage of the last-named plant has somewhat suffered from the cold of winter. *Rehmannia angulata* is a useful subject for the greenhouse. The indoor plants were wintered in cold frames, and were plunged in ashes with a layer of sifted leafsoil spread over the surface of the pots.

CYTISUS ALBUS.

THIS white-flowered Broom has long, wiry shoots that are laden with bloom early in June. It grows well and flowers abundantly here among a bank of old Laurels. This plant resents much pruning when it has reached a good size, and it is not a long-lived subject, but, being readily raised from seeds sown as soon as they are ripe, there is no difficulty in maintaining a stock. Pot the seedlings when they are large enough and place them under glass, where cool treatment is afforded. Shift them later into 5-inch pots, and stand them in the open until October, when they can be planted in their permanent quarters. A spadeful or two of rich loam and leafsoil will be helpful to them if applied at the time of planting. Nothing further is necessary except supplies of water during dry weather. *J. Mayne, Bicton Gardens, East Devon.*

ARUNDO DONAX (THE GREAT REED) AND ITS FORMS.

It is remarkable in what a number of ways one can use the Great Reed and in every instance find the association a happy one. This is another way, perhaps, of saying that it will grace any position that may be assigned to it, and whilst this is an undoubted fact, the plant requires from the cultivator the best attention he can afford it, from the landscape gardener his best skill in finding for it a position worthy of its grace, and from the owner of the garden some such measure of protection as he is accustomed to afford to trees, shrubs, and herbs destined to form permanent features in the landscape. It is not the plant for a planter in a hurry, for it will probably take several years to reach its maximum height, and at least ten years to develop into massive clumps possessed of an inimitable beauty and a stately grandeur rivalled only by the best of the Bamboos. By an unwritten law which everyone recognises, but which no one strictly observes, the *Arundo* should be isolated, not as individuals, but as a group from other groups. The ideal "setting" is that afforded by a carpet of grass or low herbs that admits of every erect stem and gracefully recurved leaf being seen at its best. Its own rigid yet graceful outlines forbid a muddle at its base, and it requires no help from other plants save from those modelled on its own stately scale, and these other groups should be widely separated from it and each other.

Itself an old-time plant, it accords well with old-time surroundings, and is peculiarly fitted for association with garden architecture, as "sentinel" groups guarding a massive garden gateway and as a corner group to destroy the

too acute angle of a walled-in enclosure. The outlines of the plant being a study in straight lines and curves, it serves a useful purpose in blending with an English landscape garden designs from warmer climes, notably those of the Italian school. Here are the straight canals, straight paths, straight balustrading, straight pergolas, straight beds, &c., &c., that accord so well with Italian roofs and terraces, but which need some modifying influence to blend them with English mansions and their environment. This influence the *Arundo* provides in a surprising measure, and its intervention carries the eye from the straight lines to free grouping without abrupt transition.

It has unlimited value in the garden landscape also. It is an excellent subject for bold grouping by the waterside, for planting in the open glade, in the Bamboo garden, or wherever there is moisture, a good soil, and particularly where there is abrupt transition from the formal garden to the informal. The type plant of the Mediter-

the leafage is produced in similar proportion. It proves to be quite as hardy as the older type *Donax*, but whether it will reach 14 feet in height or surpass it I have no knowledge. It has formed clumps of from six to eight stems each, and the stems are from 6 to 7 feet high, from tiny scraps planted three seasons ago: the current year's shoots are remarkably vigorous.

A form of *A. Donax* named *variegata* is quite different. It is a comparative weakling, and the least that is said about it in connection with garden landscape the better. It is wholly incapable of withstanding ordinary winters unharmed, but for the greenhouse, the cool conservatory, and for water-gardens under glass it is a splendid subject. This variegated form does not exceed 6 feet in height, and is inclined to branch too freely at the base: in every respect, however, it is the best of all variegated grasses, and the finest coloured. *Pandanus Veitchii* cannot surpass in beauty a well-filled pot of *Arundo Donax variegata*.

FIG. 155.—SOME OF THE GLOXINIAS EXHIBITED AT THE RECENT TEMPLE SHOW BY MESSRS. J. FEED AND SONS.

ranean reaches a height of from 12 to 14 feet in this country. It must have the best of culture, however, or a maximum of 10 feet is all that can be expected; shelter is necessary from violent winds, and the plant must be cut down to the ground level every April in order that the young grass may grow away unhindered. This annual pruning maintains the plant in vigour for a great length of time.

If the old growths are left, the young shoots live as competitors; numbers of off-shoots from the old stems and much of the plant's vigour thus goes in undesirable channels.

A new variety, with which I have been acquainted for about four years, promises well. It is named *macrophylla glauca*, and the name describes it well. The growths are stouter than those of the typical *Donax*, and, in addition, the stems and leaves are very glaucous, but grandly effective. There is a denser vegetation also, and for every single shoot a *Donax* sends up the variety *macrophylla glauca* sends up three, and

The planting of these grasses should be performed in April when the soil is thoroughly warmed. The roots start within a week of planting, and suffer no check thenceforward. A cartload of good loam is a necessity for every plant destined to live undisturbed for many years, aided by an annual mulch of cow manure every spring after the old stems are cut away.

Propagation, other than that by root division, is possible in good warm seasons such as 1906, by cutting the stems, when removed in the following April, into foot lengths, leaving a node or two on each piece, and sticking them in sand in a tub three-parts filled with water. Place the tub in a warm greenhouse; shoots will issue from every piece of stem that is fresh and green within a month or two of severance; these should be raised to high-water level till roots are emitted. The severance of the new plants from the old stem and their establishment in pots is the final treatment in their propagation by cuttings. *G. B. Mallott.*

KEW NOTES.

ALPINE GARDEN.

EREMOSTACHYS SUPERBA.—Although the genus *Eremostachys* consists of some 27 or more species, all natives of Western and Central Asia, the only one well known in gardens is *E. laciniata* from Asia Minor. This handsome species has been in cultivation since the year 1731, and is quite an attractive plant, its woolly spikes bearing pleasing purple and brown-coloured flowers. *E. superba*, a species having deep-primrose-coloured flowers, and a native of the Western Himalayas, is a welcome addition to this family. Seeds were received at Kew in 1902 from the Warsaw Botanic Garden, and the plants have flowered there for the first time this year. The pinnatisect leaves are produced in a rosette at the base of a simple stem,

flowers. A good figure of this plant is given in the *Gardeners' Chronicle*, 1897, XXI., p. 182, from a photograph taken in its native habitat on the Cilician Taurus, at an elevation of 5,000 feet, where it grows in open rocky places. It first flowered at Kew in 1896, and the plant was drawn and figured in the *Botanical Magazine*, t. 7,742. The rosette of large handsome leaves of a glaucous hue at their base gives the whole plant a stately appearance. In its native habitat it reaches a height of 7 feet or more.

CONANDRON RAMONDIODES.—Although introduced into cultivation by Messrs. J. Veitch & Sons, Ltd., in 1879, this plant is still rarely seen in gardens. It is now in flower in the Alpine house at Kew, having been accommodated through the winter in a cool house. It has not proved hardy at Kew, and although it will stand the severity of the winter, provided a

two to three flowered, and foliage possessing 12 to 20 leaflets. The flowers are rose coloured, with a purple base, and are freely produced. It first flowered at Kew in 1905, and is figured in the *Botanical Magazine*, t. 8,054. Thriving under the same conditions, both species are now flowering in pans in the Alpine house, after having been grown plunged in ashes in a frame with a northern aspect.

PODOPHYLLUM VERSIPELLE.—In the rock-garden at Kew this recently-introduced Chinese plant is now producing its pendulous chocolate-coloured flowers. The species is a native of China, where it is found in woods and shady situations in Western Hupeh and Eastern Szechuen. *Podophyllum versipelle* is a singular-looking plant, with stems nearly 3 feet in height, dividing into two near the top, each portion bearing a large, lobed, peltate leaf 18 to

FIG. 156.—MESSRS. SUTTON AND SONS' STRAIN OF SCHIZANTHUS.
(From a photograph kindly supplied us at the Temple Show.)

which reaches a height of about one foot, while the flowers are borne in woolly heads 4 to 6 inches in length and 3 to 4 inches broad. Although a dwarf plant, it is a very attractive one: it has proved quite hardy at Kew, and as easy of culture as the older *E. laciniata*.

MICHAUXIA TCHIHATCHEFFÜ.—A fine specimen of this handsome biennial is now in flower at Kew on a warm border facing south. This species may sometimes be had in bloom within 18 months from seed-sowing, but frequently a period of two or three years, or even more, elapses before the flower-stems are produced on seedling plants. The Kew specimen has a stout flowering-stem between 4 and 5 feet in height, with lateral branches from the base upwards, the whole being covered with large white

cold frame be afforded it, the plant is not a success under those conditions. It is a close ally of *Ramondia* and *Haberlea*: the leaves are large and in colour deep green. The inflorescence is an elegant drooping cyme of purplish rose or white flowers with a purple eye. This *Conandron* grows naturally on moist rocks on the mountains of Nippon and Kinsin in Japan, and, when growing, requires plenty of moisture, but not of a stagnant nature. It is figured in the *Gardeners' Chronicle*, 1879, II., p. 232.

OXALIS ADENOPHYLLA.—This Chilean species was collected by Mr. H. J. Elwes, near San Martin, at an elevation of 6,000 feet. It forms an excellent companion to the Falkland Island species, *O. enneaphylla*, but differs from that plant in having a bulb-like rootstock, peduncles

20 inches in diameter. The flowers are produced in bunches of from 12 to 16 just under the leaves, and they are more curious than ornamental. The value of the plant lies in its bold, handsome foliage. It is quite hardy, and grows luxuriantly in strong soil.

PENTSTEMON CÆRULEUS.—One of the earliest of the genus to bloom, this species is also distinct by reason of the charming light blue of its flowers, which are produced in dense panicles. In habit the plant is about 9 inches high, and the narrow leaves are glaucous. Treated as a biennial, it forms a pretty pot subject, besides being useful for planting out in a warm, sheltered part of the rock garden. The plains of Dakota and Montana in the Western United States are its native habitat. W. I.

TREES AND SHRUBS.

DEAD WOOD ON TREES.

FAR too much dead and dying wood is allowed to remain on our park and woodland trees, the result being a sense of neglect and untidiness, danger from falling branches, and the encouraging of injurious insect pests. By the removal of dead branches cut well back to the living wood, young growths are induced to form and an improved condition of the trees results both in health and in appearance. Travel where one will, the same conditions are seen, and the presence of stag-headed trees and dead or dying side-branches are more often the rule than the exception. On well-managed estates the pruning of ornamental timber trees is regularly attended to, but often on smaller properties, where a forester is not employed, this condition of untidiness prevails. Possibly the cost of removing dead wood from trees is one reason why it is often neglected, but when the health of the tree, its generally improved appearance, and the enhanced value of the property of which it forms a part are considered, the expenses incurred thereby will be more than recompensed.

THE EARTHING-UP OF TREE STEMS.

This is a ruinous practice, and often the cause of unhealthy and dying trees in parks and woodlands. When a quantity of surplus soil has to be disposed of, a site beneath a clump of trees or about the woodland margin is generally chosen as the most convenient and out-of-the-way position where such may be placed. Few persons fully realise the amount of damage that is caused by the indiscriminate placing of soil deeply beneath and around the stems of even large and vigorous-growing trees. When soil has been placed to a depth of, say, from 3 to 4 feet, the trees will usually die out in a year or two, but in our parks and gardens the covering soil has been lighter and the decay is slower. First, the foliage becomes meagre and rusty, next the branch-tips die back, the bark loosens and falls off in flakes, and gradually the whole tree succumbs to what might well be termed root-suffocation.

A light top-dressing of good soil will benefit rather than injure a tree, but it should not be of a greater depth than 4 inches. Where it is imperative that several feet in depth of soil must be added to the woodland, then the only chance of saving the trees is to leave a space about 6 feet in diameter around the stem of each large tree, and on this reserve area little or no top-dressing should be added.

ORNAMENTAL WILLOWS.

Apart altogether from the value of the osier and the timber obtained from these trees, several species are highly ornamental and eminently suited for planting by the stream or lake side. For this purpose the Carter or red-twigged Willow is particularly effective in its extremely dark red branches, as is also the Golden Willow (*S. aurea*), which, for clump planting by the water side in conspicuous positions, has, perhaps, no equal. *S. sanguinea* has clear, shining bark of a rich vermilion colour, which appears beautiful in the setting sun of an autumn day. Another desirable species is *S. regalis*, the Royal Willow, and though introduced fully a century ago, is not half so commonly planted as its merits deserve. The foliage is of an almost unique silvery tint, and it associates well with those of the purple and golden kinds. Among weeping kinds are the desirable and well-known Kilmarnock Willow, the Babylonian Willow, and American Fountain; the last-named was introduced from France about the year 1852. Willows are readily raised from cuttings. They are inexpensive and beautiful, and one wonders why they are not more often planted. A. D. W.

NOTICES OF BOOKS.

THE UNHEATED GREENHOUSE.*

By Mrs. K. L. DAVIDSON.

THIS is a carefully-compiled and charmingly-written book, containing a mass of interesting, useful, and practical matter regarding the selecting and arranging of the most suitable subjects for rendering the unheated greenhouse attractive and engaging during the late autumn, winter, and spring months. The work consists of 248 pages, wherein the advantages attached to an unheated greenhouse are indicated in a clear, interesting, and very readable manner. There are 46 good illustrations. The book is divided into 22 chapters, dealing with the following subjects:—The Advantages of an Unheated Greenhouse; Typical Cold Greenhouse; Some Hints on Construction; Regulation of Temperature; Plants Suitable and Unsuitable; The Alpine House; Foliage Plants for Grouping; Bulbs and Tubers—Hardy Species; Half-Hardy Species; Lilies; Flowering Shrubs; Some Hard-Wooded Plants; Roses; Hardy Perennials for Spring; Autumn Perennials under Glass; Annuals and Biennials; Hardy Orchids; Succulent Plants; The Potting Shed—Summer Quarters; and Routine Work.

The manner in which each subject indicated above is treated shows that the authoress is not only a close observer of all that is interesting and beautiful in plant life, but that she also has a practical knowledge of the requirements and cultural treatment of the plants enumerated. At page 4 an additional plea is urged in favour of the unheated greenhouse, in that it affords an opportunity to the delicate amateur gardener of both sexes to indulge in the pleasure derived from watching and tending to the requirements of plants at a time of the year when it would be unsafe for them to work out-of-doors. "It is no small boon, then, on a dreary winter's day to have a place of shelter, neither too cold nor too hot, and a possible occupation where an hour or two may be safely spent in the company of the plants we love."

The unheated greenhouse may take on occasion the form of a glass corridor, and when this happens to be a lean-to passage-way connecting garden structures, or it may be outlying rooms of a dwelling, it is a place of all others in which to grow specimens of flowering shrubs (page 4) such as *Carpenteria californica*, which succeed best when trained against a wall, and which are all the better for having their root-room restricted by a narrow and not too deep border. The roof may also be embellished with hardy climbers such as *Clematis* and *Jasmines*, *Tea Roses*, &c. *Agapanthus* and *Crinum Moorei* and similar strongly-growing plants would also succeed in the unheated corridor, and should be grown in tubs or in large Italian pottery.

Practical and useful hints are given at pages 15 to 22 on the construction and aspect of glass-houses suitable for the growth of certain kinds of plants named. Glazing, shooting, and underground covered-in cement tanks for the storage of rain-water are all dealt with in a clear and expert manner, as also are such details as the regulation of temperature, ventilation, and shading.

Each of the 98 pages of excellent appendices (in which lists of various kinds of plants suitable for growing in the unheated greenhouse are given) is divided into five longitudinal columns in which, reading from the left are given (1) name, (2) height and colour, (3) native country and season under glass, (4) soil, (5) general remarks.

The book can be recommended with every confidence of its affording pleasure and useful information to all who consult its pages. The paper, type, illustrations, and text are all alike good, and the matter, from the beginning to the end of the book, is not only expressed in a clear and practical manner, but has literary charm in addition. "The Cool Greenhouse" would perhaps be a more appropriate name for the book, seeing that frequent reference is made therein (pages 2 and 5) for the provision of means for preventing the temperature falling below 35°.

The Week's Work.

FRUITS UNDER GLASS.

By ALEXANDER KIRK, Gardener to J. THOMSON PATON, Esq., Norwood, Alloa, Clackmannanshire.

Fruit-trees in Pots.—Apples, Pears, Plums, &c., in pots will now be swelling their fruits, and the latter will require a final thinning, which should be severe in the case of weakly and unhealthy trees. Syringe the foliage both morning and evening when the weather is hot, and give abundance of ventilation to the orchard-house. Afford liberal supplies of water as often as necessary, and liquid manure at the roots twice a week. Support any branches which are fruiting heavily, by means of a strand of bast tied to the main branch. Supply the plants with a rich top-dressing during the time the trees are maturing their crop.

Strawberries.—Batches of these plants, in a late Peach or Orchard house, that are required for late fruiting should be watered twice daily during hot weather, for if the foliage is allowed to flag, it will soon become infested with red spider, and this pest also soon attacks Strawberries on shelves near to the glass at this season. Syringe the plants with hot water each morning, which will greatly assist in warding off mildew and red spider. As soon as the fruits are set, thin the berries to about eight or nine of the best on each plant, and afford a stimulant to the roots once or twice every seven days. Support the trusses of fruit with forked twigs, or, better still, with patent wire stakes; this will keep the fruits clean and prevent the weight of the fruit from bending the stalk over the sides of the pots. Plants that have furnished early supplies of fruits this season should now be sufficiently hardy for planting in the open borders, where they will fruit well next year.

Cucumbers planted in hot-beds must have their shoots regularly pinched and pegged down. Spray the foliage lightly when the frames are closed for the night during the hot weather. Never allow the young shoots to become overcrowded, but remember that Cucumbers planted in hot-beds make gross growths. Do not over-crop the plants. As soon as the heat from the decomposing materials declines, apply a lining of short green grass and stable litter all around the frame. This will enable the plants to continue fruiting for another month. Sow seeds for providing a succession.

Melons which were planted in frames last month should have their flowers pollinated each day. Pinch the young growths, and when three or four fruits are "set" on each plant remove any others as they appear. Thin the young growths when they are too thick to allow plenty of sunlight to reach the fruits. Do not allow the bottom-heat to decline, but, instead, line the frames afresh with grass and leaves mixed together to maintain a steady temperature.

THE HARDY FRUIT GARDEN.

By J. MAYNE, Gardener to LORD CLINTON, Bicton, East Devon.

Gooseberries.—In gathering these fruits those nearest the ground should be selected first. For bottling purposes the fruits should be picked before they are large. Warrington is a good variety for bottling, and the present is a suitable time for thus conserving them. Guard against the Gooseberry caterpillar and keep the ground well stirred beneath the bushes with the flat hoe on every favourable opportunity. Should there be any suckers present, cut them out early, as these rob the top growths of nourishment.

Recently-grafted trees of Apple and Pear need examining, and where union between stock and scion is apparent the clay or wax should be removed, the ligatures loosened so that swelling may be unrestricted, and a small stick or tutor be secured to the stock and the graft tied to prevent injury from birds and wind. A few shoots from the stock may be allowed to remain until the growth of the scion is well advanced. Any of the grafts that are still plump, though dormant, should be syringed several times daily to encourage the buds to burst.

Raspberries.—Established plants usually throw up far more growths than are required for next season. They should be thinned considerably, reserving only the strongest shoots that are nearest the stool. Autumn fruiting varieties should be treated similarly and be given a heavy

mulching of manure. The drainings from the stables or cow stalls may be poured on the roots of these plants at any season of the year; it will help the fruit-crop later on and strengthen the young canes which will furnish next year's fruits.

Apples.—Early varieties that have set heavy crops of fruits should be moderately thinned at first, for if they are thinned again in a few weeks time the fruits will then be serviceable for use in the kitchen. It is a great mistake to allow trees to carry more than a fair crop, especially trained trees. American blight increases fast at this time of the year, and should be combated vigorously, using methylated spirit, Gishurst Compound, or diluted paraffin for its destruction. The grass in orchards should either be eaten off by sheep, or be mown with the scythe, but the stems of young fruit-trees must be protected from sheep or cattle. Mown grass should be placed around the younger trees; it will keep the roots moist and cool, and is especially valuable in the case of sandy or gravelly soils.

Protecting fruits with nets.—Numerous birds in this locality remind one that preparations must soon be made to ward off their persistent attacks on the fruit crops. Do not wait until colouring in the fruits indicates ripening, but make preparations as soon as stoning is finished. Early Strawberries growing on south borders should be netted immediately they pass out of flower. In case the weather should be showery during the Strawberry season, it is advisable to place about three sticks around each plant, and to tie the fruit trusses clear of the litter and foliage, especially of that robust variety Royal Sovereign, whose canopy of foliage completely hides many of the fruits, and hinders the sun from reaching the berries. Where mice abound, traps should be set in the vicinity of the beds.

PLANTS UNDER GLASS.

By J. G. WASTON, Gardener to H. J. KING, Esq.,
Eastwell Park, Kent.

Souvenir de la Malmaison Carnations.—The main batches of these plants are now fast approaching their flowering stage, and it will be necessary to see that the bands by which the flower-stems are tied are not too tightly fastened, otherwise the stalks will snap as growth develops. Remove the lateral flower-buds as early as possible, and also afford the blooms, before they have fully opened, the requisite support. The "Ascott" is one of the best supports for this purpose, and it can be procured in various colours to suit the different varieties. Shade the blooms from strong sunshine, or they will quickly lose their colour. Keep the house cool and well ventilated, and on very hot days, damp occasionally the staging between the pots.

American-tree, or Winter-flowering Carnations.—The term winter-flowering is somewhat misleading, for although in common with many other plants they may be flowered in winter, they probably flower better as the days lengthen and the amount of sunlight increases. Perpetual blooming they certainly are, and this name would appear to be more appropriate for them. A batch of these plants from which flowers were cut in mid-winter have at the present time more flowering-shoots and better blooms than ever, and have every appearance of still continuing to flower for a long period. Plants required for flowering next autumn and winter should now be repotted into their flowering-pots and, if the weather is favourable, be stood outside on a bed of ashes. In more northern localities or in places where the rainfall is heavy, they should be placed where they can be protected from inclement weather. In all cases, when newly potted, they should be protected from continuous heavy rains, and if nothing further can be done in this direction, it will suffice if the pots are placed on their sides for a day or two. Pinch the points out of the shoots, to induce a bushy habit, but do not practise pinching too late in the season. Afford stakes to the plants as required, and syringe them occasionally in the evening with weak soot water; this will help to ward off insect pests and will also stimulate the roots. Remove the plants in September, early or late, according to the locality, but it is better to err in housing the plants indoors too early, rather than to allow them to become saturated with heavy autumnal rains. Late-rooted cuttings should be potted as required,

for on no account must they become pot-bound. This later batch of plants will flower in the winter if their shoots are not pinched too late in the season, but the quantity of bloom will be much smaller from them than in the case of the earlier plants.

THE KITCHEN GARDEN.

By WILLIAM H. HONESS, Gardener to C. COMBE, Esq.,
Cobham Park, Surrey.

Tomatos may now with safety be planted in the open. Place a good strong stake to each at the time of planting, for if this were done later there would be the danger of damaging the roots. Make the plants firm in the soil, and if they be thoroughly soaked before turning them out of the pots, further waterings may not be necessary for several days. Tomatos planted at the foot of walls a fortnight or more since will now require attention in the matters of watering and tying.

Onions both spring and winter sown, including those that were transplanted, are now making good growth. The former are quite large enough for salads. Any gaps in the rows should be made good by transplanting. In gardens where spring Onions are in demand for salads, periodical sowings should be made throughout the summer. The hoe should be frequently applied between the rows of Onions to keep the soil porous and sweet, and if hoeing is well carried out, very little weeding will be required.

Root Crops.—Parsnips, Carrots, Beet, Turnips, &c., will now require further thinning, and this is better done at intervals and when possible during showery weather. In the case of Carrots apply a sprinkling of soot along the rows immediately after the plants are thinned. This will check the maggot, which is often particularly active after the operation of thinning.

Cardoons.—The present is a suitable time for planting this vegetable in trenches already prepared, as advised in a previous calendar, keeping them well supplied with water. Should the seedlings appear too forward, make another sowing immediately, as very early plants are apt to "bolt."

Gourds and Pumpkins are often used in winter in soups, and in the autumn time they are in demand for harvest festivals. They are also objects of interest when growing up posts or when allowed to ramble over out-houses and trellis work, and there are many curious and pretty varieties. A spent hot-bed that has been used for early Carrots, Lettuce, &c., makes a good rooting medium for these curious plants, provided the surroundings will permit of their rambling at will.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower to Sir TREVOR LAWRENCE,
Bart., Burford, Surrey.

Cypripediums.—Amongst the species of Cypripedium now in flower are the rare *C. Sanderianum* and *C. caudatum*. The former thrives best when placed in a shady corner of the hottest house, while *C. caudatum* prefers the cooler atmosphere of an intermediate house, and a position where it can obtain plenty of fresh air and sunlight. Unfortunately both these Cypripediums are seldom met with in a flourishing condition in gardens. The rare and curious Uropedium *Lindenii* is closely allied to *C. caudatum*, and it should be afforded exactly the same treatment. Other species and hybrids now in bloom in the warm house include *C. superciliale*, *C. Stonei*, *C. barbatum*, *C. Curtisii*, *C. Rothschildianum*, *C. Swonianum*, *C. macrochilum*, *C. Lawrenceanum*, *C. L. Hackbridgensis*, *C. callosum* *Sanderæ*, &c. After their flowering period is over these plants should be examined at their roots and be afforded more rooting space if necessary after first removing the old flower-scapes. A mixture of rough, fibrous peat, sphagnum-moss, and broken crocks will form a suitable rooting medium for them all. About one third of the depth of the pots should be occupied by drainage material. After repotting, keep the surface of the compost just moist, but afford abundance of water when the plants are re-established, and at all times shade them from bright sunshine. *C. superbiens* (*Veitchii*) flourishes in a shady part of the Cattleya house, and if it is grown in a warmer structure the delicate foliage is liable to become infested with small yellow thrips. All the Cypripediums requiring cool treatment, including *C. insigne*, *C. Leeanum*, *C. villosum*, *C. Boxallii*, *C. Sallieri*

Hyeaunum, *C. Euryades*, &c., are now in their full growth and will require copious waterings at their roots whenever the compost appears the least dry.

Cattleya labiata.—Plants that are showing their flower-sheaths should be given plenty of water, until their new pseudo-bulbs are fully developed, after which time the amount of moisture at their roots should be considerably reduced, giving only sufficient to prevent the pseudo-bulbs from shrivelling. Immediately the flower-buds are seen pushing through the sheath, the quantity of water must again be increased, but at no time should plants of this useful Cattleya be kept in a saturated condition, and each plant should become properly dry before water is again applied. These remarks apply also to *C. gigas*, *C. Dowiana*, and its variety *aurea*.

Plants of Vanda "Miss Joaquim" which are showing their flower-spikes should be placed near to the glass so as to obtain the maximum amount of light, on the south side of the East Indian house. A similar position in the Cattleya-house will suit the rare *Renanthera Storiei*.

Shade-loving Orchids, such as *Bolles*, *Pescatoreas* and *Warsceviczellas*, should be placed in a damp corner of the Cattleya or intermediate house, and be given a position where they will be protected from all direct sunshine. In addition to the ordinary shading, it is advisable to place a garden mat immediately over them during the hottest hours of the day. They must be kept well sprayed with water overhead all through the summer months, and they will need plenty of water at their roots for several months to come.

PUBLIC PARKS AND GARDENS.

By W. W. PETTIGREW, Superintendent of the Parks and Open Spaces in the City of Cardiff.

Children's playgrounds.—In the majority of public parks, children's playgrounds now occupy an important place. These are somewhat diverse in character, and even in the same town it sometimes happens that they are not all conducted on exactly the same lines. Some may be furnished with swings, see-saws, giant strides, and sandpits, while others may simply be part of the recreation ground that is set aside for the use of small children only. Where a whole acre or more space can be spared for a playground, it is well to have it turfed, and there is then little need for swings and such like amusements. It, however, the space is limited, it had much better be asphalted and provided with the additional means of amusement above indicated. In the latter case it is essential to have a smart able-bodied caretaker always in attendance to keep the children under proper control and to prevent accidents. There seems to be a considerable divergence of opinion among various authorities as to the value of swings and gymnastic apparatus in children's playgrounds. Some, during recent years, have discontinued, while others have extended, their use in playgrounds. In congested areas, where it is impossible to get a large open space for the use of children, swings, &c., supply the only form of amusement that can be adequately provided for them under the circumstances. In the larger spaces there is little need for such adjuncts as these, for the children will furnish their own amusement in games, &c.

Infants' playgrounds.—It may seem somewhat ridiculous to suggest that the addition of an infants' playground might be found exceedingly useful in a public park. Such an institution, however, has been in existence in one of the pleasure gardens in this city for a number of years past, and has proved such a decided success that the idea is about to be extended. The one in question is an isolated lawn about 1½ acres in extent, and is kept regularly mown with a machine, so that the grass is always short. Here the little ones are allowed to amuse themselves, and as no games are permitted in the vicinity there is less danger of these infants getting injured, as sometimes they would in an ordinary children's playground. One has only to visit this park on a fine summer's day and see the infants' portion covered with little ones to realise how greatly it is appreciated by them and their parents. In a crowded city it must be a very great boon for parents to be able to take or send their babies to a place where they are absolutely free from ordinary dangers.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the **PUBLISHER**, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the **EDITOR**, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Special Notice to Correspondents.—The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.

Illustrations.—The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but he cannot be responsible for loss or injury.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY, JUNE 10—

Unit. Hort. Ben. and Prov. Soc. Com. meet.

TUESDAY, JUNE 11—Roy. Hort. Soc. Coms. meet.

WEDNESDAY, JUNE 12—

Roy. Cornwall Sh. at Liskeard (3 days).

Roy. Bot. Soc. Summer Exhib. (3 days).

THURSDAY, JUNE 13—

Colonial Exhib. at R.H.S. Hall, Westminster (3 days).

SATURDAY, JUNE 15—German Gard. Soc. meet.

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich—68°6'.

ACTUAL TEMPERATURES:—

LONDON.—Wednesday, June 5 (6 P.M.): Max. 66°; Min. 54°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—Thursday, June 6 (10 A.M.): Bar. 29.6; Temp., 62°; Weather—Bright.

PROVINCES.—Wednesday, June 5 (6 P.M.): Max. 67°, Cornwall; Min. 50°, Scotland N.

SALES FOR THE ENSUING WEEK.

WEDNESDAY—

The beneficial interest in the lease of the Nursery, High Road, Clapham, and afterward the whole of the stock of Palms and Plants. On the premises, by order of the executors of the late G. B. Fischer, by Protheroe & Morris, at 12.

Geraniums, Carnations, Pinks, &c., Palms, Bays, &c., at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.

FRIDAY—

Imported and established Orchids in variety, at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.45.

It is our melancholy duty to record the death of **DR. MAXWELL TYLDEN MASTERS, F.R.S.**, Editor of this journal, who passed quietly away to his rest on the 30th ult. at his residence at Ealing, after an illness extending over a period of one month.

The name and personality of Dr. Masters have so long been associated with the *Gardeners' Chronicle* that our minds may have unconsciously imagined a state of permanence to exist in regard to something in which permanence is impossible. How difficult it is to bring ourselves to write of our revered chief as one who has gone for ever from our midst!

So long ago as forty-one years last November, Dr. Masters first became part editor of the *Gardeners' Chronicle*. Dr. Lindley died on November 1, 1865. His death was briefly announced in the issue for November 4, and in that of November 11 there appeared a short biography of the great botanist, written by Dr. Masters—probably the first article he contributed after his appointment. During all the subsequent years, the influence of the mind, character, and ability of Dr. Masters has been stamped upon these pages. It is not our intention to write at length on the details of the life and published

botanical works of our chief. The loss we have sustained is of far too personal and painful a character. In our next issue another pen will do for our readers this important service, also necessary in the interests of botanical and horticultural science. In the meantime, we recall some of the more important questions upon which, as Editor of this journal, Dr. Masters was led to use his influence either in the guidance of public opinion, or in giving expression to the wishes and thoughts of his readers. He entered on the consideration of all such matters with a mind absolutely free from prejudice of any kind and from all mean or selfish motives. A purist of the most uncompromising kind, his policy was determined by one question, and that alone: Which is right? No thought of mere expediency ever influenced him. The right course was to him the only course. This marked conscientiousness was indeed his chief characteristic, and next to this was his extreme kindness. It is conceivable that those who were less familiar with the leader we now mourn, may have been so impressed with his kindly nature that his other equally excellent qualities were less conspicuous to them. But they were just as real. Those who came into daily association with Dr. Masters could never mistake his kindness for vacillation, or his extreme desire to avoid hurting the feelings or prospects of others, for weakness. Occasions have arisen when his heart would fain have prompted him in one direction, but his judgment and unswerving obedience to the dictates of conscience have obliged him to proceed in another. His sympathies were of the widest description. In every branch of botanical and horticultural science he found occasion to interest himself. His mind was too catholic to allow him to form a partisan appreciation of particular flowers, or even of special forms of gardening. He saw good in everything, and possessed the enviable gift of being able to exhibit that good to others.

His memory for circumstances that happened many years ago was remarkable. Many a time has Dr. Masters referred to the excellent botanical lectures that Dr. Lindley used to deliver in the Physic Garden at Chelsea more than fifty years ago. He always described them as the most interesting scientific lectures he had ever heard.

Dr. Masters has told us of the incidents attending the fight he undertook in the pages of the *Gardeners' Chronicle* on behalf of the interests of good gardening, when a proposal had been made in respect to the management of the Royal Gardens at Kew, which would have placed the care of the plants in the hands of a Government department, instead of in those of the Director. This was probably the longest sustained fight that Dr. Masters ever waged on a political question. He won the day, and events have proved that he was right. Most of the circumstances connected with that somewhat embittered controversy were as fresh in his memory as ever.

Another subject in which he always maintained the liveliest interest was that of the great International Horticultural Exhibition of 1866, of which the late Sir Charles Wentworth Dilke was president. Dr. Masters acted as Congress Secretary for that event, which proved, it may be remembered, so

financially successful that there was a large balance, of which £1,000 was given to the Gardeners' Royal Benevolent Institution, and the remainder applied to the purchase of the Lindley Library. The exhibition has now a melancholy interest for us. For some years past it has been the custom of Dr. Masters to make a special note when death overtook a member of the Committee that was charged with the arrangements for that exhibition. One by one they have passed away. Since the death of Richard Dean, the only two surviving members were Mr. Harry J. Veitch and Dr. Masters. A month or two ago the latter, after drawing our attention to this fact, remarked that copies of the photograph, being exceedingly rare, it would be interesting to publish it as a supplement to the *Gardeners' Chronicle*. The photograph was prepared for publication, and the intention was to have issued it in Temple Show week, with some reminiscences that Dr. Masters alone was in a position to write. Unfortunately, his fatal illness commenced so suddenly the reminiscences were not prepared, and the photograph was put back for use after his hoped-for convalescence. To-day, when we mourn his loss, there appears no reason for further delaying the publication of the photograph. It is, indeed, appropriate to a number relating the entering into rest of one who edited the account of the 1866 "Proceedings."

Another subject Dr. Masters used to talk about freely was the Royal Horticultural Society. He was always one of its most loyal supporters. The assistance he was able to give to the reforming party towards the close of the South Kensington period was extremely valuable. The important incidents connected with that uninspiring chapter in the society's history were as fresh in his memory as ever, including the extraordinary measures that were adopted to preserve the Lindley Library from the probable confiscation by the society's creditors.

At a much more recent date the late Editor felt it his duty to oppose the proposal that was made to purchase a new garden for the society, when it had no better place in which to hold its fortnightly exhibitions than the Drill Hall in Buckingham Gate, and no building of its own that could be used as offices. The wisdom of the opposition on that occasion is now generally recognised, and how perfectly the feelings of the great body of horticulturists were expressed in these pages was proved by the extraordinary enthusiasm with which the "Hall" scheme was subsequently taken up, the satisfactory completion of the building, and the excellent uses to which it is now applied.

Dr. Masters used to relate many interesting incidents connected with the society's old gardens at Chiswick, and our readers will remember how reluctantly he at length acknowledged the need there was for relinquishing them before the expiration of the lease. Nevertheless, when the late Sir Thomas Hanbury presented the Wisley Gardens, he was as delighted as anyone, and from that date he pleaded for the establishment there of a research department and laboratory. Whilst he lay ill an invitation was addressed to him from the Council to attend the opening ceremony of this station on July 19 next, but he knew not of its receipt.

THE LATE DR. MAXWELL TYLDEN MASTERS, F.R.S.
(From photographs taken in 1873 and 1897.)

THE INTERNATIONAL HORTICULTURAL EXHIBITION OF MAY, 1866.—MEMBERS OF THE EXECUTIVE COMMITTEE.

Back row (standing), reading from left to right :—Charles Turner, Charles Lee, Richard Dean (Assistant Secretary), William Paul, John Gibson, Charles Edmonds, John Standish, John Lee, William Bull, E. Easton, B. S. Williams, T. Osborn.

Front row (sitting) :— Dr. Hogg (Secretary), R. Fortune, Thomas Moore (Secretary), Sir C. Wentworth Dilke, Bart., M.P. (Chairman), Sir Daniel Cooper, Bart. (Treasurer), Dr. M. T. Masters (Congress Secretary), Prof. Bentley, James Veitch, Harry J. Veitch.

Temple Press Ltd., Printers, 7-15, Rosebery Avenue, London, E.C.

The Ghent Quinquennials were attended by Dr. Masters on almost every occasion since 1870. He was unable to attend the last one in 1903, owing to temporary indisposition, but had already commenced to consider the possibility of witnessing the exhibition to be held in April next. The late President of the Société Royale d'Agriculture et de Botanique de Gand, Comte de Kerchove de Denterghem, was one of his personal friends, and he was greatly affected by the Count's death in March last year. Dr. Masters' warm-hearted sympathy and practical interest in the gardening charities are almost as well known to our readers as to ourselves.

The latest movement that gained the sympathetic interest of Dr. Masters is that of the British Gardeners' Association, which was inaugurated at a meeting at which he presided. He was convinced that gardeners might do much good for themselves by co-operation for mutual help. He deplored the fact that practical gardeners are not, as a rule, treated with the consideration and liberality that their training and ability deserve, and in co-operation believed that much might be done by gardeners themselves to raise their status as a body of scientific workers. He did not approve the methods of trade unionism, but such co-operation as would secure for every man perfect individual liberty, and afford help to all in their efforts to improve themselves and their position. On the very day that he fell ill he intended to write a letter for publication in the first issue of the *Journal of the British Gardeners' Association*, the notes for which he had already prepared.

His interest in the Scientific Committee of the Royal Horticultural Society, over whose deliberations he has presided since the retirement of Sir Joseph Hooker, were sustained until the last, and although latterly he sometimes felt fatigued after a busy day at the Horticultural Hall, he always remained for the meeting of this Committee at 4 o'clock in the afternoon. As chairman of the trustees of the Lindley Library he regarded the trust as one of the highest importance, and although his efforts to raise sums of money for the purpose of purchasing new books, re-binding old ones, and preparing a catalogue were often so unsuccessful that many would have been disheartened, he was not discouraged. It was a matter of satisfaction to him to know that a catalogue had been published, that the Library is suitably housed in the new building, and that the whole of the books have been rearranged and classified in the most convenient manner for easy reference. Dr. Masters was also Chairman of the Veitch Memorial Trustees, and until recently of the Williams Memorial Fund, the management of which has now passed to the Royal Horticultural Society.

Maxwell Tylden Masters was born at Canterbury on April 15, 1833. He was the youngest son of Alderman Masters, a well-known and intellectual nurseryman of that city, whose *Hortus*, published in 1831, is still preserved in libraries, and affords a good indication of his appreciation for science rather than love for commerce. The son was educated at King's College, London, and, after obtaining his degree, went from

King's College to Oxford as sub-curator of the Fielding Herbarium, under Dr. Daubeny. He also practised medicine for some time, commencing at Peckham in 1856, and it was during this period he commenced the compilation of *Vegetable Teratology*, on the suggestion of his friend, James Salter. From 1855 to 1868 he was Botanical Lecturer at St. George's Hospital, and for some years was Examiner in Botany at the University of London and for the Society of Apothecaries. He became a Fellow of the Linnean Society in 1860, and in 1870 was elected a Fellow of the Royal Society. Dr. Masters was a corresponding member of the Institute of France, and an officer of the Order of Leopold.

At the time of his appointment as co-Editor of this journal, in company with the late Thomas Moore, Dr. Masters was only 32 years of age. During his Editorship many important changes have been made in the paper. In 1865 the *Agricultural Gazette* still formed a part of the weekly issue, the price being sixpence. In 1862, after the removal of the stamp duty, the price was reduced to fivepence. A rapid extension in the practice of gardening made greater claims upon horticultural literature; therefore, in 1873, the connection with the *Agricultural Gazette* was severed, and the extra space has since been devoted to gardening matter. In 1887 the price was further reduced to threepence. It may be stated here that William Masters, an elder brother of Dr. Masters, was a member of the Editorial staff, under Dr. Lindley, and had had much to do with the preparatory work before the publication of the first issue in 1841.

On Wednesday, May 1st, Dr. Masters was at his place in this office as usual, and he believed himself to be in his ordinary good health. On Thursday an examination by the physician revealed the presence of pleurisy, which was followed on Friday by pneumonia. From the hour of the first attack until his lamented death no one was permitted to see the patient other than his immediate relatives and medical attendants. He had ceased all work in connection with his beloved *Chronicle*, and was not allowed even to see the weekly issues. The Temple Show came and he had no knowledge of its occurrence, but remarked on the opening day that he supposed it was an "ordinary Tuesday." It was the first of the twenty shows that have been held in the Temple Gardens that he had not visited. Hopes of recovery were entertained up to the very last, and the Doctor never for a moment suspected that death was approaching, but heart failure supervened, and our beloved Editor passed to his rest on Thursday afternoon whilst the copies of our last issue were being rapidly printed, and the show on the Embankment was in course of dispersal.

The funeral took place on Tuesday last. There was a service at St. Stephen's Church, West Ealing, and this was attended by a few representative horticulturists. The remains were subsequently cremated at Woking.

Thus has terminated one of the most useful careers in horticultural history. The memory of Dr. Masters will be cherished, and though he has passed from us, his example will remain for ever an incentive to our best efforts.

TRIBUTES FROM CORRESPONDENTS.—Many letters have reached us containing expressions of regret at the loss which botany and horticulture have suffered in the death of our late Editor. We desire to thank our correspondents, but it would be impossible to publish all the communications.

—Dr. Masters loved his work and the *Gardeners' Chronicle*, the reputation and high standard of which he ever sought to preserve and uphold. His work was a delight to him, and his life "so full of interest," as he often said, threw him into the society of many notable people, both at home and abroad. Few men allowed themselves so little recreation, and beyond a short holiday once a year he was rarely absent from his post. He liked to spend his time when off duty in his little study at home, reading or writing, or enjoying his small garden, which contains some of the plants called by his mother "his queer things" and many living "memorials" of friends obtained from their gardens—friends who themselves, alas! have in many cases passed away.

Dr. Masters was Lecturer on Botany at St. George's Hospital from 1855 to 1868, Examiner in Botany for some years at the University of London and for the Society of Apothecaries. He gave a course of lectures when quite a youth at the London Institution and another at the Royal Institution. It was during the busy period of his medical life in 1860 that he compiled, at the instigation of his friend, James Salter, F.R.S., his work on *Vegetable Teratology*, for which he had collected much material. This was published by the Ray Society, and is still the standard work on this subject.

Dr. Masters was also the author of *Botany for Beginners*, of *Plant Life* (of both of which French, Dutch, and Russian translations have been made), and of numerous monographs and papers on subjects relating to botany, vegetable physiology, and horticulture. He was a frequent contributor to scientific periodicals, and took part in Oliver's *Flora of Tropical Africa*, Hooker's *Flora of British India*, Von Martin's *Flora Brasiliensis*, De Candolle's *Prodromus*, the *Encyclopædia Britannica*, *The Pinetum Britannicum*, and other works, besides preparing the second, third, and fourth editions of Hensley's *Elementary Course of Botany*. Conifers also received much attention in his later years. He was the most amiable and the most honourable of men, and his liberality and generosity were only kept in check by the slenderness of his purse. It was only the modest and retiring disposition of Dr. Masters that prevented him from receiving even more widespread recognition of his services to science than he has done. Those who knew him best loved him best, and can most truly say and feel that his loss is irreparable. E.

—It is with great sorrow I contribute a few lines to the memory of one whom I had known intimately for upwards of 40 years, and with whom I had been associated for more than a quarter of a century on the Scientific Committee of the R.H.S. Others can speak of his scientific work, and of his position as Editor of the *Gardeners' Chronicle* for 41 years; but my memories cling more to personal matters of continual harmony and friendship. Being always ready to communicate his knowledge of, and views on, botanical subjects, I derived much benefit from him in various scientific directions. He often alluded to the botanical assistance he derived from my father in his younger days, and he never hesitated to return it in full to the son. As an admirable Chairman of the Scientific Committee since Sir J. D. Hooker retired from the post which he held when the society was at South Kensington, Dr. Masters always showed his invariable courtesy towards everyone, whether in inviting discussion, or giving suggestions for further enquiries on indecisive matters, and in every way encouraging us to advance the interest of the scientific aspect of horticulture. No one can be more missed than he. *George Henslow*.

At the annual dinner of the Kew Guild, on May 27, Mr. George Massee, who presided, made some good-humoured criticisms of gardening as it is commonly practised. Fearing that all praise and no fault-finding would not be calculated to inspire efforts towards improvement, he found occasion to read several lessons, which, greatly exaggerated as they were, may not have been without value to those who listened to his remarks. One of the failings specially rebuked was that of cultivating an excessive appreciation for primary colours and introducing these into the flower garden to the exclusion of all intermediate shades. This is a conspicuous error in some gardens, and there can be no doubt but more satisfying effects and greater refinement are obtainable from a system in which gradation of colour, and colour-harmony are given proper representation. In the pruning and lopping of trees there is just as much need for improvement, but in this respect the collection of trees and shrubs at Kew afford an object-lesson of the good results that follow a moderate degree of pruning and training, one in which the cutting of trees of different habit to one stereotyped form is avoided, and yet proper care taken to assist by judicious pruning the development of good specimens. The "mixed" flower border, likened by Mr. Massee to a "trial" border, has always caused considerable controversy, and in no part of the garden is greater care and better taste needed than in the selection of suitable plants for such positions. The chairman was equally critical in regard to the workers in the herbarium, and besought botanists to get beyond the "species" stage. It was all very well to name new species, but botanists should utilise the species as a groundwork for further research.

Mr. Curtis, in responding for the Guild, and Dr. Henry, in a subsequent speech, showed how greatly disseminated are Kew men, and Dr. Henry, referring to the present condition of Kew Gardens, stated that, although he had travelled widely, so far as he knew there was "no spot in the world so beautiful as Kew."

ROYAL HORTICULTURAL SOCIETY.—The Committees of this Society will meet on Tuesday next, June 11, in the Hall in Vincent Square, Westminster. In the afternoon, at 8 o'clock, Mr. WALTER P. WRIGHT will deliver a lecture on "Arches, Pillars and Pergolas."

BOTANICAL MAGAZINE.—The following subjects are illustrated in the issue for June:—

RHODODENDRON DELAVAYI, tab. 8,137.—This Chinese species is very similar to forms of *R. arboreum*, as was stated by Mr. W. WATSON in *Gardeners' Chronicle*, 1904, vol. xxxv., p. 262. *R. Delavayi* has intensely red flowers with black blotches on the inside. It has been in cultivation in Europe for nearly 20 years, and at Kew previous to 1894, but has never flowered there. The figure was prepared from a specimen from the garden of Mr. THOS. ACTON, Kilmacurragh, Wicklow, where it first flowered in 1904. The note is contributed by Mr. W. BOTTING HEMSLEY.

TAMARIX PENTANDRA, tab. 8,138.—A species described by Dr. STAFF as growing wild in countries extending from the Balkan Peninsula through Southern Russia to Turkestan, and from Asia Minor to Persia, adorning the banks of the rivers. The flowers are usually rose-coloured, but some-

times white or nearly white. The species has been known as *T. Pallasii* and a note by Mr. BEAN was printed in these pages on September 23, 1905, p. 229, under the name of *T. Pallasii* var. *rosea*.

EUPATORIUM GLANDULOSUM, tab. 8,139.—This Mexican species was figured in the *Botanical Register* in 1835, tab. 1,723. Mr. HEMSLEY now considers *E. trapezoideum*, Kunth, of which a note by Mr. ROLFE appeared in *Gardeners' Chronicle*, May 5, 1906, p. 274, to be synonymous.

GENTIANA ORNATA, tab. 8,140.—The plant originally described in the *Botanical Magazine*, tab. 6,514, is not the true *G. ornata*, and no dried materials of the specimen figured having been preserved, its identity cannot now be established, but it is considered to be near *G. nipponica*, Maxim. A note by W. I. on the plant now figured, of which Mr. HUTCHINSON supplies the description, was published in *Gardeners' Chronicle* on September 8, 1906, p. 112.

DENDROBIUM ASHWORTHIAE, tab. 8,141, and O'BRIEN in *Gardeners' Chronicle*, February 9, 1901, p. 86, fig. 36.—A plant of this species now in the collection of Sir TREVOR LAWRENCE, Bart., at Burford, is believed to be the only surviving specimen in Europe. The flowers are creamy white with a few purple streaks at the base of the lip. The description is by Mr. ROLFE.

R.H.S. COMMITTEES' OUTING TO BURNHAM PARK.—Those members of the Royal Horticultural Society's committees who were present at the ordinary meeting on May 14 will remember that a cordial invitation to visit East Burnham Park, Slough, at an early date, was given them by Mr. HARRY J. VEITCH, V.M.H., and a game of cricket on the excellent ground there was suggested. The week of the present month beginning on the 17th is considered as presenting the most favourable time for the trip, and it will be for the members of the committees in conference when they meet on the 11th inst. to fix which day of that week other than Saturday will be most convenient for the majority. Mr. VEITCH generously intimates that he will provide conveyances for the party from Slough Station to East Burnham Park. He invites all members of the committees who may desire to accept his invitation, and trusts that those who do not play cricket will yet find ample means of spending a very enjoyable time. Intending cricketers, writes a correspondent, will do well to employ the interval in polishing up their batting and bowling. As the entire party should not exceed 80 in number, it is hoped that those desirous of joining the excursion will inform Mrs. H. J. VEITCH at 34, Redcliffe Gardens, South Kensington, S.W., at an early date. Generally, it is hoped that all coming from London will travel to Slough by the 10 a.m. train from Paddington, and those coming from other directions will endeavour to reach Slough about 10.30 a.m. at the latest. East Burnham Park is some four to five miles from Slough Station, and therefore it will be most convenient if all the party can assemble at Slough at the same time. Any, however, who cannot possibly reach Slough at the time stated, should in their acceptance state the time when they will arrive.

GOOD PRICES FOR ASPARAGUS.—There was a fine exhibition of Asparagus in Evesham Town Hall on Monday, May 27, writes Mr. J. UDALE, and at the close the whole of the exhibits were sold by auction. The bundles contained 120 heads each. The heaviest bundle weighed 24½ lbs., and sold for 48s. The best bundle in the show realised 50s.; others sold for 40s. 6d., 35s. 6d., 28s., 26s., 25s., 21s., and 20s., respectively. The remainder—between 80 and 90 bundles—realised from 17s. 6d. per "100" down to 4s. 6d., the majority realising upwards of 10s. per "100."

NEW YORK INTERNATIONAL CONFERENCE ON PLANT HARDINESS AND ACCLIMATIZATION.

—The Horticultural Society of New York have inaugurated a conference on these subjects to take place from September 30 to October 2 in the rooms of the American Institute and the Museum Building of the New York Botanical Garden. The second day, October 1, will be devoted to some form of pleasure, possibly an excursion to a place of interest in the neighbourhood.

POULTRY CONFERENCE.—We have received a copy of the provisional programme of the second National Poultry Conference, to be held at Reading on July 8, 9, 10, and 11 next. Those who require particulars should write to the general secretary, Mr. EDWARD BROWN, 12, Hanover Square, London, W., or to the local secretary, Miss RIDLEY, Orwell House, Reading. There is an influential local committee at Reading, of which Mr. LEONARD SUTTON is chairman.

CABBAGE LETTUCE MAIKÖNIG (MAYKING).—

When this variety first came into commerce, now some few years ago, the verdict of the gardeners was that this was a first-class novelty. For a time, indeed, it was possible to get seeds true to name, but it is now very difficult to obtain seeds that produce a plant of the quality once so good. It was supposed by some growers that the variety was not constant. The raiser, H. DAVID SACHS, of Quedlinburg, states in the *Deutsche Gärtner Zeitung* that it always came true with him, but that in the following autumn, after he sold his stock of the variety, other seed, under the name Maikönig, from France and elsewhere, was offered at very low prices, and this fact has brought discredit on the variety. The true Maikönig is described as a quick grower, every plant forming a good heart, and they withstand hot, dry weather. According to H. SACHS, the variety makes any other quite unnecessary. If sown under glass in January and February and planted in the open air at the end of the month of March, it affords hard-hearted Lettuces as early as the ordinary autumn-sown varieties. It is equally valuable planted in cold frames. F. M.

THE PERPETUAL FLOWERING CARNATION.—

This is the title of a brochure by MONTAGU C. ALLWOOD, and published by HUGH LOW & Co., Bush Hill Park. The book is a practical one, written by a cultivator who knows his business and how to convey instruction in a pleasing manner. If, after consulting its pages, a gardener or amateur fails in the attempt to grow the new type of winter-flowering Carnation, Mr. ALLWOOD must be held innocent, for the instruction he supplies and the advice he tenders are alike admirable. There is little connected with the "American" Carnation (a designation objected to by the author) that is not clearly described, and though there may be nothing advanced which is not already well known to the trade grower, gardeners will find many cultural hints of much value. The instruction given regarding the stopping of the different varieties, of which a list is supplied, is extremely valuable, and that is only one of many hints equally desirable. There are short chapters on the Souvenir de la Malmaison type and on Border Carnations. The author is, however, mistaken in asserting that the production of flowers of Souvenir de la Malmaison varieties out of season "is not practised by any grower without loss and uncertainty," and in assuming that they must be forced to flower in winter. There is a good chapter on pests and diseases, as well as one on manures, and these are somewhat marred by compositors' mistakes. The book is well illustrated.

THE GARDENERS AT KEW.—"Few of those who are acquainted with the Royal Botanic Gardens at Kew will be other than surprised, to say the least, at the statement recently made in the House of Commons by Sir E. STRACHEY that the men employed at Kew are not properly gardeners, but only apprentices. It appears that the Kew men have asked for the same conditions of employment as the Government concedes to men of the same age and character in the Royal parks, such as Hyde Park, not to mention the L.C.C., whose men are even better treated. Certainly, the condition of the gardens at Kew is one that reflects credit on that section of the staff which is responsible for its management, and if such high-class gardening as is there displayed can be accomplished by apprentices, who, we are told, are not paid wages, but receive only what is called "a subsistence allowance," we recommend other Government departments to adopt the Kew apprentice system. On inquiry, however, we were informed that Sir E. STRACHEY's statement was incorrect. The facts are, that some 60 journeymen gardeners of the average age of 24 years, who must have had at least five years training in good gardens before entering Kew, are employed to do the work, for which they are paid wages of 21s. per week, their hours of labour being from six to six, or daylight to dark. From what we understand of this question, the Board of Agriculture is not dealing fairly with a body of men whose work is a proof of their skill and assiduity, and that it is appreciated by the taxpayer is proved by the large crowds that daily visit the gardens for instruction and enjoyment. We have every reason to be proud of Kew, and in our opinion the treatment of the employees should be such as would not justify complaint."—*Field*, June 1.

RETIREMENT OF MR. MCINTYRE.—This well-known Scottish gardener is retiring from his charge of The Glen Gardens, Innerleithen, Peeblesshire, in which place he has been head gardener for the past 30 years. He proceeds to Honolulu, where several members of his family reside. As an exhibitor and judge, writes a correspondent, Mr. MCINTYRE was most courteous, his unassuming manner rendering him very popular. For many years he has been one of the leading exhibitors at the Royal Caledonian and Scottish Horticultural Society's shows, winning many valuable prizes. It will be remembered that Mr. MCINTYRE was the recipient of the Neil prize given by the Royal Caledonian Society in 1900 as a successful cultivator and botanist. Mr. and Mrs. MCINTYRE have received presentations from the garden employees at The Glen.

CAULIFLOWER AND CABBAGE ROT.—Our valued correspondent, Dr. COOKE, writes: "For many years Cabbages and Cauliflowers in the United States have suffered from attacks of Black Rot, which has been attributed to bacteria, under the name of *Pseudomonas campestris*. During the past two years the same vegetables growing in the vicinity of the Missouri Botanical Garden have been affected with a dark rot, which at first was attributed to *Pseudomonas*, but latterly the disease has been found to have quite a different origin. Although it is affirmed that Bacteriosis is responsible for more diseased plants than all other causes, yet the present pest is likely to inflict serious injury, and, as it is known in this country and in Europe generally, as affecting other plants it is a serious matter. This rot is more watery than that caused by bacteria, and the diseased tissues are not so dark in colour. The younger growing portions of the plant are favourite places of attack. The petioles of the leaves are often rotted away at their base, the leaves droop, and the fungus grows down through each leaf, rotting it, and often forming sclerotia on the thinner portions. Sometimes older plants of

Cauliflower are attacked at the base, and rot off, before the inflorescence becomes diseased. The fungus produces a white fluffy mycelium, but it is not stated whether the presence of conidia has been observed, under the form of botrytis, although this is probable. The rot is often accompanied by numerous black specks, which are the sclerotia, and from these, by culture, have been developed the peziza-forms, well known under the name of *Sclerotinia Libertiana*. These sclerotia have been observed, after remaining dry for over a year, to throw off filaments, develop an extensive mycelium, and form new sclerotia, thus indicating great vitality at this stage. The cup-like receptacles, which terminate each stalk-like development from the sclerotia, are trumpet shaped, with, at first a convex cup, then flattened, and ultimately concave when mature, and of a light brown colour. The inner surface of these cups is covered by the hymenium, or fructifying portion, and consists of cylindrical sacs, or tubes, each containing eight ascospores, measuring 9-13 by 4-6 mm. Inoculations with the ascospores produced the typical rot of the Cauliflower. These details are taken from the reports of the Missouri Botanical Garden, but, at present, they are not accompanied by any suggestions for combating, or the results of any experiments, in the control of the disease. The fungus is described in Dr. COOKE's *Pests of Cultivated Plants*, p. 102, as Cucumber sclerote, and is probably also the same as that which attacks Potato haulms. One precaution may be taken, by burning all infected plants at once, and thus preventing the spread of the disease.

AMATEUR AND PROFESSIONAL ROSE GROWERS.—A note in our American contemporary *Horticulture* upon the methods of the American Rose Society serve to remind us how perfectly our own National Rose Society has won the esteem and support of both amateur and trade growers. Many of the American horticultural societies represent trade interests almost exclusively, and our contemporary remarks that if ever popular enthusiasm is to be awakened on behalf of a National Rose organisation in the States, it will undoubtedly be by the employment of very different methods from those that have proved effectual in the upbuilding of the professional societies to which we have alluded. The circumstances are so different in England that at every exhibition of the National Rose Society there are Roses staged by new amateur exhibitors, and it would be difficult for the visitor to estimate whether the nurserymen or amateurs have the greater enthusiasm for cultivating and exhibiting their flowers. The American Rose Society may, therefore, be recommended to ascertain from the genial secretary, Mr. ED. MAWLEY, by what means such a satisfactory condition has been brought about.

DINNER TO CONTINENTAL HORTICULTURISTS.

—A company of 220 foreign horticulturists recently visited London in order to inspect the Temple Flower Show, Kew Gardens, and other places of horticultural interest. The party was entertained at dinner on the second day of the Temple Show by a number of British horticulturists, in the King's Hall, Holborn Restaurant, under the presidency of Mr. J. S. BRUNTON. The foreign friends were numerous, and the company included M. HUGUENET (Editor of *La Chronique*), Mr. GEO. SCHNEIDER, M. LAGEAT, M. GAB. DEBRIE, several officials of the Alliance Fraternelle Internationale, M. L. CHENAULT, M. LETELLIER, of Caen, and Mme. VACHEROT, M. G. VAN DEN HEEDER, Mr. F. SANDER, M. C. DELONCLE, the Mayor and Mayoress of DUNKERQUE, &c. The usual loyal toasts having been honoured, the Chairman proposed the toast of "Our Guests," which he did in the warmest terms of welcome, and with references to visits spent abroad with brother horticulturists. The speech was translated into

French by M. DUMONT, the Mayor of Dunkerque. Responses came from M. DELONCLE, Deputy of the Seine and President of the Federation of French Horticultural Syndicates, who replied on behalf of the French visitors in an excellent speech full of friendly allusions to the organisers of the great gathering and admiration at the grand exhibits they had that day seen at the Temple Show, which had been of great educational value to them. Messrs. NEUBERT and KOENEMANN replied for Germany. They called attention to the Mannheim Exhibition, and read a telegram from the Burgomaster of that city offering a hearty welcome to all English horticulturists. M. RUVS, in excellent English, replied for Holland, repeating his speech in French for the benefit of those visitors who were unacquainted with English. Belgium was represented by Mr. F. SANDER, who, in an able speech, referred to the extensive commercial relations existing between Belgium and Great Britain. The Mayor of DUNKERQUE, Sir THOMAS BARCLAY, M. LEBEL, and several others also made speeches.

DEPARTMENTAL COMMITTEE ON AGRICULTURAL EDUCATION.—This committee, of which Lord REAY is chairman, held meetings on May 28, 29, and 30. Mr. J. MARSHALL DUGDALE (nominated by the Royal Agricultural Society of England), the Vice-Chancellor of Oxford, Sir OLIVER LODGE and Mr. WALTER E. COLLINGS, Birmingham University, Mr. RICHARD P. WARD, the Director of Education Cheshire County Council, Miss MAY CROOK, of Bredon's Norton, Tewkesbury; representatives of the University College, Reading; Hampshire Farm School, Basing; and of Studley College, Warwickshire, attended and gave evidence.

NATIONAL CHRYSANTHEMUM SOCIETY'S OUTING.—The annual outing of the members of this society will take place on Thursday, June 20, when, by kind permission of JEREMIAH COLMAN, Esq., a visit will be paid to Gatton Park, Surrey. The whole of the grounds and greenhouses at Gatton will be open for the inspection of the members. Brakes will convey the party to Gatton, and also from Gatton to Redhill for lunch, and during the afternoon there will be a drive through the surrounding country. Tea will be served at Redhill. Tickets, price 10s. 6d. each, which includes railway fare, dinner, tea and drive, can be obtained from the secretary, Mr. RICHARD A. WITTY, St. James's Villa, Swain's Lane, Highgate, London, N.

CARNATION PEST—ALTERNARIA.—Mr. WOODS, of the Department of Agriculture, U.S.A., gives some important information respecting this new Carnation pest. He says: "The disease is quite serious on the softer-leaved varieties, such as those of the Lawson type, especially the Lawson and the Enchantress. The disease behaves very much like the other *Alternaria* diseases, especially the one on the Violet, attacking not only the leaves, but the stems, cutting the plants back very seriously in many cases. In fact, I have seen whole houses of Carnations practically stripped of their leaves, and losing a large part of the top. Plants grown out of doors, exposed to rain and dew, especially in the night, are very subject to the disease and suffer seriously when the plants are moved from the house. It is, of course, then rather difficult to free the plants of the disease, without cutting them back very severely and spraying them thoroughly with soap Bordeaux (mixture). The proper treatment is to spray the plants from the time they are set in the field until the time they are moved into the house, keeping the young growth well covered with Bordeaux, and continuing the treatment after the plants are in the house until they become well established. If the plants are grown in the house all the year, and the leaves are not allowed to remain wet overnight, the disease seldom, if ever, does much injury."

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

THE PRESERVATION OF PLANTS BY STEEPING AND SAND-DRYING.—Decorative plants may be made to preserve their freshness and beauty for some considerable time by the employment of a method discovered by an Italian. The method employed consists in washing the roots thoroughly, so as to remove every particle of earth from them, and then to cover the plant with dry sand in a box. Care must be taken that the leaves do not fade or shrivel, and that those packed closely together do not ferment, otherwise the foliage, when dry,

sand thus prepared will last for a considerable time. The fatty matter is to prevent the sand from sticking to the roots or foliage, and the salicylic acid and alcohol prevent fermentation and preserve the colour. A box of sufficient size to permit of the branches being stretched out their full length without crushing them must be used. The box should have thin sides and a sliding bottom, and on the top a grating with spaces sufficient for the sand to pass through. At the bottom of the box is placed a thin layer of sand, and then the plants, leaves, or branches are placed as much as possible in their natural positions, and the sand is dropped in through a sieve or funnel so as to fill every interstice closely. When the plants are covered completely with sand, the box is placed in a stove or oven

bonate of copper for two or three hours, according to whether the plants are much faded, and whether an intense green is required or not; they should then be hung up to dry, and placed in a preparation consisting of glycerine. J. J. Dunnington-Jefferson.

SUCCULENCY DUE TO SALT.—The fleshy Primrose described on p. 322 has, of course, become succulent by the direct action of the salt, as M. Lesage long ago proved to be the case with maritime plants.* A very similar occurrence takes place at Bad Nauheim, where a salt spring rises as a natural fountain, some 10 or more feet in height, and the water is conducted to a construction for condensing the brine. An erection of faggots, some 60 feet in height in a frame-work,

FIG. 157.—MESSRS. W. BULL AND SONS' EXHIBIT OF ORCHIDS AT THE TEMPLE SHOW.
[For details see last issue.]

will turn black. In order to prevent this happening, the plants are plunged into a solution of salicylic acid in the proportion of one part of the acid to 600 parts of alcohol, heated in a water bath. It is only necessary to place the base of the leaves and of the larger branches in the solution for some hours. For plants of finer growths, such as *Asparagus plumosus*, the lower parts are immersed in a solution of 15 parts of alum and two parts of nitre to 80 parts of water, in which they must remain for four days. If only the leaves and branches are required to preserve, it will be sufficient to immerse their bases in the solution, and in this manner the natural colour of the foliage remains unimpaired. One may also use the sand of fine gravel, well screened, and cleansed from all earth, and dried thoroughly in the sun or in a stove, with an emulsion well mixed, composed of 70 parts of alcohol to three of stearine, three of paraffin, and four of salicylic acid. The

heated sufficiently to dry its contents thoroughly in six hours, after which it is taken out, and a day or two later the sliding bottom is removed so that the sand falls through below, leaving the branches and leaves sterilised but uninjured. In Germany a different method is adopted for sterilising green plants, each leaf having a hot iron passed over it to remove any moisture from the tissues and to prevent fading. To further secure absolute dryness, each leaf is placed flat between pieces of blotting paper. To give the leaves their former suppleness, and to make their colour lasting, they are steeped in a bath containing carbonate of copper and alcohol for half an hour, and then hung up separately to dry. After two or three days they are given a coating of white varnish and are again hung up to dry, after which they may be arranged to form a decorative plant. If the plants are faded and it is desired to make them green again they should be steeped in a bath containing car-

forms a long wall. The brine is pumped up to the top of this, and as it trickles through the faggots the water evaporates and the denser brine is collected below. The effect upon the plants in the neighbourhood is to make several of a more or less fleshy character than is normal to them. I collected specimens of *Plantago*, *Atriplex*, *Daucus*, *Spergularia*, &c. The influence was most characteristic in the first-named plant, and its appearance was so altered as to resemble *P. maritima*, the leaves being long and without teeth or small projections as in *P. Coronopus*. There were plants of various sizes; the largest had leaves 1 foot in length, the scape measuring 1½ feet, with the flower-bearing extremity 3½ inches long. As the nearest sea-board is some 200 miles off, I would suggest that it is a local evolution of a new species or variety of *P. Coronopus*. George Henslow.

* *Rev. Gén. de Bot.*, vol. ii., pp. 55, 106, 168. Also *Comptes Rendus*, cxii., 1891, p. 672.

TO PRUNE OR NOT TO PRUNE.—The judicious pruning of fruit trees is too well established a practice to be injured by anything that Mr. Simpson may write against it, but any unnecessary mutilation of the trees deserves condemnation. Neglect with regard to careful pruning and manuring is largely responsible for the immense quantity of inferior fruits seen in our markets. During the past 42 years, which embraces the period of my horticultural experience, probably all of our best fruit-growers have been pruners. If we pass to commercial fruit-culture, we find similar results: the men who prune, manure, and spray are the men who obtain commercial success, because they obtain the highest average quantity and quality of fruit. Since May 15, I have received six letters from as many fruit-growers living within a radius of 15 miles of Droitwich, and together they cultivate a total area of 664 acres of fruit of all kinds—partly arable and partly grass. Each gentleman states that he annually prunes his fruit-trees; and, even in the case of old orchards, they prune more or less every year, according as they can find time. There is no sentiment in their case, but strict business methods, for fruits of good quality must be obtained in abundance to afford a profit. Within a radius of six miles of Evesham there are more than 9,000 acres of land devoted to the culture of fruits and vegetables, and practically the whole of this land is dug or ploughed. Plums, Gooseberries, and Strawberries are the staple fruit crops, and in the order here given. Apples are not much grown, but their cultivation is extending, and I observe that the trees are generally trained as bushes and half standards. The varieties of Plums grown are mainly Pershore, Victoria, The Czar, River's Early Prolific, Damascene, White Magnum Bonum (so-called), and Heron. Of these, Pershore, Damascene, and Magnum Bonum—which is either Abricot or White Perdrigon—require little pruning, owing to their habit of growth; the other varieties need and receive more attention in this respect. The Pershore Plum is such a reliable fruiter in this county that it is a great favourite, and is grown in large quantities. I have said it requires and receives little pruning, hence, it is easy for a stranger taking a chance journey through the county of Worcester—especially in certain directions—to form the erroneous opinion that pruning, in a general sense, is little practised. The experimental results published by the county of Worcester are as trustworthy as daily note-taking, careful weighing, and measurement can make them. *James Udale, Droitwich.*

—The subject of the pruning of fruit trees is so important commercially that it demands a full discussion, and though I have no desire to share in the controversy between Mr. Udale and Mr. Simpson, certain facts which have come within my own experience may be placed on record. As a rule, after the first year's training of a bush or standard tree in a nursery or elsewhere, the tendency is to either prune too much or not at all, and the happy, reasonable mean has been the exception. Both these extremes are to be condemned. Within the past 18 months my journeys have covered an area extending from Yorkshire to Cornwall, and during this time some hundreds of commercial fruit and vegetable gardens have been inspected. In the majority of the young and recently-formed plantations the hard pruning formerly too conspicuous is being rapidly discarded for a more common-sense procedure, because experience has proved the increased money value of the much heavier crops of Apples and Pears thus secured. The fact is when once the foundation of a well-developed tree is formed, the sooner pruning can be reduced to the lowest point, consistent with maintaining an equal distribution of the branches, preventing either crowding or the production of long, straggling growths, the better will be the prospect of securing paying crops. This is especially the case where the trees grow very vigorously, and, in consequence, remain comparatively unfruitful. Root pruning is often a remedy in such instances, but it frequently happens in market plantations that neither the expense, labour, nor time can be found for this operation, the reduction or temporary cessation of branch pruning, in these instances, forming a cheaper and commonly efficient means of correcting the evil. Add to this a judicious thinning of the fruits, and the result, in nine cases out of ten, is highly satis-

factory to the grower. In one large plantation of comparatively young Apple trees under my observation, the trees had borne but few fruits, but growth had been extremely strong. They had been previously pruned severely, and not with much judgment, early each autumn, but it was decided to leave them unpruned last season, and all have flowered with great profusion. The remarkable point was, however, that, on a careful examination of 50 trees of different varieties in different parts of the 20 acres, I found that, taking an average, nearly 80 per cent. of the shoots bearing trusses of flowers would have been removed in any pruning of the type which had prevailed. A fortnight after the examination in question another plantation was seen, where identically the same practice had been followed, only the reduction had been commenced the year before. The soil and conditions were similar, and the trees were about the same age, but the improvement was most noticeable, as less unduly vigorous wood had been produced, and there was a greater proportion of the desired fruit-spurs forming. The owner had resolved henceforward to confine his pruning to thinning and moderate shortening where necessary. As regards the older plantations and orchards, non-pruning has, unfortunately, resulted in the grossest neglect, and I have seen scores of examples in the Western counties where trees that might have been handsome, productive specimens are nothing but thickets, which are only reduced when the owners are in want of firewood. *Lewis Castle.*

STRAWBERRY ROYAL SOVEREIGN.—As the growers of the large fruits of this Strawberry, referred to by *F. M.* and *A. D.*, we should like to say that they were the largest ripe fruits picked from a batch of about 600 pots. During their season of forcing they were given three applications only of a fertiliser, and weak manure water was applied the same number of times, which certainly does not represent gross feeding. As growers for market we do not over-thin the fruit, but always expect to have a fair crop of large fruits, which last year were even larger in size than they have been this year. None of your correspondents has mentioned "Sir Harry," one of the very finest forcing varieties of former times, but now worn out—at any rate in this district. President was good for some years, but it has deteriorated like Sir Harry. The variety James Veitch is a very large fruit but it is "woolly" and of poor colour. We have forced all these kinds in quantity, and now grow only Royal Sovereign, but like *A. D.* we are waiting for a better one. *S. Ledsham & Son, Chester.*

—The remarks recently made by *F. M.* (p. 304) regarding the quality of Royal Sovereign Strawberry are contrary to the high opinion formed of it by every cultivator of this and other varieties of the Strawberry that I am acquainted with. I have grown large quantities of plants under glass and out of doors of many varieties, including those mentioned by *F. M.*, during the past 35 years, and I have no hesitation in saying that, all points being considered, Royal Sovereign is, in my opinion, one of the best Strawberries in cultivation; and were I confined to four varieties I should choose Royal Sovereign, Sir Joseph Paxton, Auguste Nicaise, and Elton Pine, the last-mentioned variety planted on a north border for yielding late supplies of fruit. *F. M.* states that "many visitors to a recent meeting of the R.H.S. would doubtless ask themselves if there is merit in producing Strawberries of such enormous size," adding "that the variety has nothing to recommend it on the score of flavour, and that the size and weight of the fruits—2 oz. each—seemed scarcely desirable points in a Strawberry." My answer to the above is that the fruits in question bore evidence of high cultural skill on the part of the cultivator, and the fact of the individual fruits being double the weight of the normal size ones does not necessarily tend to deteriorate the flavour. On the contrary, I consider large fruits of good varieties of the Strawberry are better in flavour than smaller fruits of the same variety. And why should this not be so? The plants in pots are not over-cropped, the fruits being thinned out to a certain number, and they are generously and judiciously tended in the way of watering and feeding at the roots during the whole period of the plant's growth, especially while swelling their fruits. Small, starved-looking fruits afford evidence of faulty culture.

Royal Sovereign Strawberry has everything to recommend it—productiveness, large fruits of good shape, and fine flavour. The varieties mentioned by *F. M.* as greatly excelling Royal Sovereign—namely, Doctor Hogg, Vicomtesse Hericart de Thury, La Grosse Sucrée—are, as a matter of fact, very inferior to that variety in every respect, and, as might be expected, were discarded by cultivators generally after Royal Sovereign was introduced. One of the other varieties mentioned by *F. M.* made quite a stir among Strawberry-growers when it was first shown, on account of its large size—I refer to James Veitch; but to say that it is superior to Royal Sovereign in shape, colour, and flavour is a mistake: the reverse is the case. In conclusion I may say that were I limited to the cultivation of two varieties of the Strawberry, I should at once select Royal Sovereign and Sir Joseph Paxton, for, in addition to the plants being good bearers, the fruits of good size, handsome shape, bright colour, and fine flavour, are firm in texture, and stand the effects of travel well—a point not to be lost sight of. Your correspondent's remarks at p. 304 seem to suggest the erroneous idea that size in fruit is developed at the expense of quality. This assumption is wrong. If extra size is an admittedly good variety of fruit—whether it consists of, say, a British Queen Strawberry, Pineapple, or bunch of Muscat Grapes—be attained through proper cultural skill, why should the flavour of the fruit be thereby impaired? In short, why should a fruit of normal size in British Queen Strawberry be superior in flavour to one weighing 2 oz.? And, again, why should not the quality of a Queen Pineapple weighing 7 lb., or a bunch of Muscat of Alexandria Grapes of like weight, consisting of large, fleshy, well-ripened berries, be as good—not to say better—as that which characterises smaller specimens? *H. W. Ward, Lime House, Rayleigh.*

PROTECTION FROM SLUGS.—Slugs will not crawl over roughly-broken bricks. I had some put round the roots of my Peach trees last year, and no slugs attacked them. This is done in India to keep snakes out of houses. *G. M. Scriven, Watchfield, Shrivenham, Berks.*

WATSONIA ARDERNEI.—In the spring of 1905 I obtained bulbs of this handsome plant, and these were potted separately into 5 and 6-inch pots in a mixture of equal parts peat and loam, with a fair admixture of sand. The pots were stood in a cool greenhouse upon ashes that were kept moistened. They flowered fairly well during the early part of the succeeding summer. Most of these bulbs were unfortunately lost, the result, I believe, of having been kept too dry during their dormant stage. Early last year four dozen fine bulbs were received from South Africa, and these were at once potted into 6-inch pots, but on this occasion a porous soil of loam, leaf-mould, and sand was used. These plants were given the same position as the preceding batch, but they grew with more freedom, and developed tall, branching flower-spikes of pure white flowers. This spring after each bulb had successfully passed through the winter, they were given the same culture as before, but the resultant growth is deplorably weak and in no way compares with the robust, self-supporting growth made when the bulbs were first imported. The Watsonias are extremely handsome subjects, but their fickle nature under cultivation depreciates their value as garden plants. *F. W. G.*

RED CABBAGE AND PURPLE BEECH.—Will some reader who has had experience with these two plants in the same locality state whether the red-coloured form is in each case harder than the normal or green type, viz., Red Cabbage than ordinary Cabbage, and Purple Beech than common Beech? *Ruber.*

GARDENERS EXCEL AT CRICKET.—Considerable interest is taken in sport at Welbeck, especially in cricket, and his Grace the Duke of Portland, K.G., in order to encourage the sport amongst his employés, presents a solid silver cup to be competed for in a three-round, annual contest between the employés of the various departments on his estate. This year the gardeners, captained by Mr. J. Gibson, beat the house department in the final match, thus becoming the holders of the trophy. *A. R. Gould, Welbeck.*

WISTARIA AND BAMBOOS AT LATHOM HOUSE, ORMSKIRK.—I was surprised to see at Lathom House recently *Wistaria sinensis* in almost full flower. The plant is rambling over the upper portion of a wall above the roof of one of the houses 12 yards in length and a yard in width, and is planted in the west end of the glass house. Are there any other specimens north of Manchester? [Yes, many.—Ed.] My next surprise was a clump of Bamboos 38 yards in circumference and about 15 feet in height that was planted by Mr. Ashton 10 years ago. The late Earl of Lathom was very anxious to include these plants in his gardens, and Mr. Ashton was requested to select the most suitable place for them. He excavated the space 5 feet deep and filled it with a suitable compost containing a large quantity of manure. Mr. Ashton supplied me with the names, as follow: *Bambusa stricta*, *B. Métaké*, *B. tessellata*, *B. viridi-glaucenscens*, *B. nigra*, *B. Henonis*, *B. Quiloi*, *Arundinaria Veitchii*, and *A. Simoni*. An orchard house 150 feet long and 8 feet wide was planted with cordon Pears, Plums, and Cherries three years ago, and there are Peach trees of long standing on the back wall. All are well furnished with fruits. Between the cordon trees are culinary Peas in pots. There were also noticed fine crops of Figs and thousands of plants of both Tree and Souvenir de la Malmaison Carnations. *W. R.*

THE BERBERIS.—The species of *Berberis* are amongst the most beautiful of spring-flowering shrubs, and in their freedom of flowering and their graceful habit they never fail to impress the beholder with their worth. Few shrubs, when grouped together in large beds or in borders, afford a more pleasing and picturesque effect than these. Of the many species and varieties worthy of notice are *B. Darwinii*, a native of Chili, and one of our most charming flowering shrubs. Its rich deep green, box-like leaves, and profusion of brilliant orange-coloured flowers, render it a conspicuous object in any collection of shrubs. *B. stenophylla*, a hybrid between *B. Darwinii* and *B. empetrifolia*, is characterised by its arching and graceful shoots, that are clothed with small deep green leaves, and it bears a profusion of golden-yellow flowers. *B. dulcis*, or *buxifolia*, is of a rather upright habit, with solitary golden blossoms, suspended from unusually long stalks. *B. empetrifolia* is a most desirable subject for a rockery, and rarely attains to a greater height than 2 feet. Its slender branches are clothed with narrow leaves, and later in the season are studded with yellow blossoms. *F. G. Titcher.*

THE HARDINESS OF THE CAMELLIA.—It is a matter for surprise, after the experience of many years in various parts of the kingdom, that a suggestion should be made to test the *Camellia* as to its hardness. At St. Leonards, The Dell, Windsor, Glen Eyre, Southampton and on a north border at Chiswick, *Camellias* proved themselves quite hardy for almost generations. The late Mrs. Eyre Crabbe, of Glen Eyre, where noble *Camellias* are grown in all positions, some of which are fully exposed to the sun, and others shaded or sheltered, declared they were harder than the common Laurel. She once said to me, "We have often had the young shoots of Laurels killed by late frosts, but never those of *Camellia*, as they at least are not made till danger from frost is over and the old wood and leaves never suffer." *Camellias* came to us with the somewhat ignorant tradition that they were essentially greenhouse plants. Granted to have them in the greatest beauty they need glass covering, but none the less those who knew the great specimens I have seen at Glen Eyre in March, April and May, for the varieties were early and late, will admit they were fine healthy shrubs carrying enormous quantities of flowers. Mr. W. Stewart, the veteran gardener who planted them some 45 years ago, can yet happily tell how he has cut flowers from them by the barrow load each year. A suitable soil consisting of a compound of loam and peat seems to be an essential feature to their success, and none but sturdy young hard-grown specimens should be planted. *A. D.*

YOUNG GARDENERS AND STUDY.—*A. D.*, p. 305, calls attention to the general failure of young gardeners in their literary efforts and I agree with his conclusions. I recently received over fifty letters from journeymen gardeners, in answer to an advertisement, and only two expressed themselves

clearly and lucidly. What chance can a man have in securing a situation when his written application cannot be easily deciphered? It is true that many good gardeners are indifferent at composition, but the importance of good penmanship must be clear to all. I am of opinion that young gardeners do not read to the extent they should, for by reading one may learn spelling and also gain a knowledge of composition. The perusal of good books broadens the mind, and the well-read man stands a better chance of securing, and holding, the best position. *Head Gardener.*

POISONOUS PLANTS.—One hears much about the poisonous effects of certain species of *Primula*, but little about the inconvenience caused to many people in handling certain members of the Composite family, such as *Humea elegans*, *Doronicum*, *Chrysanthemum sinense*, &c., yet the inflammation produced by these latter plants is quite as severe as that caused by, say, *Primula obconica*. Perhaps some reader will elucidate the matter for the benefit of those who suffer, but who do not fully understand the cause of the poisoning and how it can be guarded against or cured? *J. Garner.*

CARBONIC ACID GAS.—I have been hoping that the question of carbonic acid gas supply, raised by me in your issue of May 4 (p. 277), would have evolved some explanations, but so far the only reference thereto has been the very interesting note of Mr. J. J. Willis (see p. 304). Obviously, the case he quotes of a bottle containing 200 ounces = 12½ lbs. of soil at Rothamsted, involves very different conditions to mine of a small pickle jar containing only about an ounce of well-washed silver sand merely thoroughly wetted. Mr. Willis speaks of the formation and exhalation of carbonic acid gas, that is to say, the carbon resulting from the decomposition of the organic compounds contained in the bottle, and this is feasible enough in the case cited by him, assuming always, and this is rather a crucial point in my primary question, that carbonic acid gas is so generated, but in my case there was practically no material for such generation beyond the minute piece of *Scolopendrium* frond base upon which the bud was present, which is now filling the bottle with fronds. That a Fern spore should have been present in such a mass of surface soil is no wonder, the wonder to me is that a forest of such and other plants did not, at any rate, start into existence in the closed bottle. I am not quite clear why Mr. Willis imputes the condensation of water on the sides of the bottle to transpiration and not to mere evaporation from the soil itself. The interior of my bottle is always wet, and would be so if merely the wet sand were inside it. This, however, is a minor point, and in any case I note with pleasure that even in the Rothamsted case, Mr. Willis echoes my query, "How is it done?" At a recent meeting of the Scientific Committee of the Royal Horticultural Society I exhibited the bottle and its contents, and as the bottle had not been sealed, but merely closed by means of a glass stopper surrounded by a very tightly fitting rubber ring, the suggestion naturally arose that it was not absolutely airtight, and Mr. Massee stated that glass was permeable by gases. How far that is the case I do not know, but I should imagine, seeing the duration of vacua in incandescent globes of extremely thin glass, that the possibility of sufficient carbonic acid finding its way through the thick glass of a pickle jar in anything like adequate quantity for the results shown is very remote indeed. Mr. Chittenden has suggested permeation through the rubber ring, which, however, was hardly exposed at all to the air, the glass stopper having a projection which covered the ring and rested tightly on the glass edge of the bottle itself. In any case, however, I have now sealed over the interstice and made the whole perfectly airtight; at any rate, in the ordinary sense of the word, though, of course, not gastight, if Mr. Massee's remark implies ordinarily appreciable diffusion. The great question, however, of the maintenance of the proportion of carbonic acid in the atmosphere, in view of the annual locking up of carbon solidified by plant action, is untouched. *Chas. T. Druery, V.M.H., V.L.S.*

SWIFT'S LEAD ARSENATE AS AN INSECTICIDE.—In the article on fruit pests of the season, p. 343, *A Working Grower* mentions the use of Swift's lead arsenate as an insecticide. The makers of this

preparation advise the use of from 1 to 3 lbs. in 50 gallons of water. Will your correspondent describe at what strength he is using this preparation with safety? With reference to the Apple sucker which he is hopeful of having banished from his trees, will he tell us as to what particular wash, winter or spring, he attributes his success? This pest is very greatly in evidence in my garden. Caustic wash applied at full strength in winter and spring has had no appreciable effect upon this enemy of Apples. *R. G.*

HARDY RHODODENDRONS.—I read with much interest the paper on hardy hybrid *Rhododendrons* in the *Gardeners' Chronicle* for June 1, but I think the writer does imperfect justice to the capabilities of *R. arboreum*. He pronounces it "not hardy, except in a few favoured parts in the south and west." Now, as it grows freely and survives the hardest winters, provided it is sheltered from violent winds, on all parts of the west coast of Great Britain from Cornwall to Rosshire, and in all parts of Ireland where the soil is not limestone, I think it would be more exact to say that there are districts where this beautiful tree cannot be grown. I wish more people could be convinced of the advantage of planting *R. arboreum*, *R. barbatum*, *R. cinnabarinum*, *R. niveum*, *R. campylocarpum*, *R. Thompsoni* and other species, instead of confining themselves to hybrids, which never present, to my eye, at least, that appearance of race and delicate harmony of blossom and foliage which the natural species possess. Castle Kennedy, near Stranraer, can scarcely be pronounced an exceptionally favoured spot in the matter of climate, for the grounds lie fully exposed to the sweep of west and north-west winds across a wide sheet of water; but there are hundreds of plants of *R. arboreum* there, some of them 20 feet high, which, although often seared on the windward side, were abundantly furnished with flowers this past spring, and after the most trying winter experienced since 1894-5. *Herbert Maxwell, Monreith.*

CUTTING ASPARAGUS.—Many gardeners continue cutting the finer growths of their Asparagus almost as long as there are any, leaving only the very smallest heads. This treatment must necessarily result in weak crowns. I cut all large and small shoots until about the second week in June, when I leave one or two strong shoots to any crowns that appear to have been hard cut, and after the longest day (June 21) none is cut. Three of our beds are about 40 years old, and I am cutting better heads probably than when I took charge of these gardens 15 years ago. Of course, the above date to cease cutting would not be suitable for all localities, but strong growths must be encouraged in order to induce strong crowns. *F. B.*

HYDRANGEAS IN TUBS FOR GARDEN DECORATION.—In the milder parts of the country all varieties of the *Hydrangea* form beautiful objects on the lawn when planted in small groups, or as solitary specimens and background plants in flower borders. In other parts, where the winters are often too cold, the plants have to be treated to glass protection throughout the winter, being stood in frames or pits, or, failing these, in some warm aspect to make their growth and ripen their shoots thoroughly, otherwise flowering is not satisfactory. If it is decided to form large specimens (they may be grown to 12-15 feet in circumference) to grow in tubs, vases, &c. Plants three to four years old, which have never been forced in heat, should be planted in late spring in a warm aspect, together with a considerable quantity of loam, rough peat, and leafmould mixed with the staple, and at a distance of 3 feet apart, affording them water in abundance in dry weather, and an occasional dose of manure water—preferably that from the cow-stalls. In the autumn these plants should be dug up carefully, the leaves, with the exception of the four around the buds, stripped off, and the bulbs laid in in a light frost-proof glasshouse. In the following spring these plants, when danger from hard frosts has passed, should be planted out as before, allowing a little more space between them, and the same sort of treatment afforded. Under three years of this kind of treatment the plants will have reached a size that will fit them for vases, &c. When once the flowering habit has been obtained it is an easy matter, with annual top-dressings with loam and manure, to keep them in health and floriferousness for many years, with an occasional thinning of the growths. *F. M.*

SOCIETIES.

BRITISH GARDENERS' ASSOCIATION.

MAY 29.—The third annual general meeting of this association was held on this date in the Essex Hall, Strand, W.C., under the presidency of the chairman of the association, Mr. W. H. Divers. There was present a company of about 80 members. The original intention to hold a conference at the close of the ordinary business was abandoned, the whole of the time being taken up by discussion. The annual report was presented, of which we extract the following:—

"During the past year the association has made steady progress in almost every direction. It has about 1,100 members, a capital of nearly £300, and an established *Journal* of its own.

At the same time the executive council would be glad if the gardeners of the United Kingdom could be brought to realise without delay the desirability of joining an association that has been established solely in their interests.

The executive council wishes to call the attention of members to the fact that journeymen and apprentices over 15, and under 20 years of age, may now join the association on the following conditions:—

(i.) That they have had at least one year's practical experience in some recognised branch of gardening at the time of application.

(ii.) That such application be accompanied by a testimonial as to ability and character from a horticulturist recognised by the British Gardeners' Association.

(iii.) That a registration fee of 1s. 6d. be paid, and an annual subscription of 1s., until such junior members become fully qualified members in accordance with rules 25 and 26.

(iv.) Junior members may attend all open meetings of the association, but shall not be entitled to vote.

The executive council recognise the desirability of instituting some commendable form of examination by which not only the professional experience and ability, but also the general education of the younger gardeners who wish to join the association will be tested.

The executive council has rejected several applications for membership from men who were obviously unqualified. By this means the association is being gradually built up into a body of competent gardeners.

The association has every reason to congratulate itself on the fact that at least one important public body—the Cardiff City Council—has recognised the value of having qualified gardeners in its parks and gardens, and that possession of the certificate of the association is regarded as a proof of professional training.

The executive council have considered the question of having a paid secretary, and will be prepared to recommend the appointment when the funds of the association permit.

The attention of the members is called to the first number of the *Journal*. For the present, at least, this is to be a quarterly publication. In the future, however, hopes are entertained that the resources of the association will be sufficient to warrant the regular publication of a monthly journal."

Mr. Divers, referring to the report, considered it generally encouraging, there being nearly 1,100 members. The question of a special certificate was deferred for the present, but it was occupying the attention of the executive council, and they hoped to procure a suitable design in the near future. He complimented the members on the appearance of the first number of their *Journal*, and he believed it to be a medium capable of doing much good for the cause. It was a band that would further unite the members, afford them a means of expressing their views on the policy of the association, enable them to ventilate their grievances, and he hoped it would not only voice their complaints, but also their expressions of loyalty to employers who were honest in the treatment of their employés. The report, together with the financial statement, which showed the society's assets to be £313 6s. 7d., and no liabilities, were adopted.

The action of the executive council in appointing a president without consulting the members was challenged. The secretary pointed out that under the rules power is granted the

council to carry out anything that is for the good of the association and not contrary to the rules. On a motion being presented to test the feeling of the meeting in this matter, only the proposer and seconder voted, and the matter was dropped.

Mr. E. F. Hawes, the treasurer, appealed for help to defray the expenses of the *Journal*, and he urged the present members to induce others to join the movement. The financial position was good, and next year he hoped it will be better.

Mr. W. Watson urged a more progressive policy for the association. There were plenty of gardeners' grievances needing redress, and he would like to see the sword drawn on their behalf. The society had done little for gardeners in the three years of its existence, and he was afraid it was because there were timid persons connected with the association. To such he would say, sever your connection with us. The progressive section might be compelled to start afresh if nothing was to be done to remedy grievances.

Mr. Purdham declared that the association was drifting away from the objects for which it was inaugurated, and that its present policy was not nearly strong enough on the side of the worker. Nursery employés in a district of North London are enquiring how to form an association. They would not join the British Gardeners' Association because its policy is not sufficiently progressive.

The secretary (Mr. Weathers) replied that at the instigation of those same men a meeting was inaugurated by him, and advertised to take place. It was not attended, and the presence of a deputy to record their names was a sufficient deterrent to prevent them attending.

At this stage it was decided to postpone the holding of a conference, and to utilise all the remaining time in discussion.

Mr. W. Watson next proposed the appointment of a paid secretary who would devote all his time to the affairs of the association. They were in a position to do this, as they had a balance of over £300 in hand, and his advice was spend as you go on, and money would follow as the result of the secretary's work and influence. It is impossible for the present secretary to do the work properly and thoroughly. His proposal was: This meeting instructs the executive council to proceed at once to appoint a paid secretary. Mr. Lyne seconded the motion.

Mr. Pearson thereupon advised the meeting to leave this matter for the consideration of the executive council, who were just as anxious as the members then assembled to take this step when circumstances were sufficiently favourable.

As an amendment it was proposed that the council be asked to again consider the question of a paid secretary. This amendment was carried by a majority of four votes.

Mr. Weathers was again appointed hon. secretary, and Mr. Hawes was re-elected hon. treasurer.

The gentlemen nominated for the executive council were elected, including Mr. Watson, Kew, and Mr. Lewis Castle was afterwards elected by the meeting to fill a vacancy.

BATH AND WEST AND SOUTHERN COUNTIES.

JUNE 5, 6, 7, 8, & 10.—This society's agricultural exhibition at Newport surpasses any of the previous shows held under its auspices.

Viscount TREDEGAR, Tredegar Park, Newport (gr. Mr. Bone), shows a group of well-grown stove and greenhouse plants, conspicuous subjects being Caladiums in variety, Palms, Acalypha hispida, Clerodendron fallax, C. Thomsonæ, Carnations, Lilium longiflorum, &c.

Messrs. J. CYPHER & SONS, Cheltenham, have a group of stove plants, Orchids, and Hippeastrums, the Hippeastrums being remarkably vigorous in growth.

Messrs. GEORGE PAUL & SON, Cheshunt, have a fine display of Roses, including such beautiful varieties as Lady Gay, Snowstorm (a new white polyantha variety), David Harum, and Rosalind.

Pelargoniums in their various sections, together with hybrid Oriental Poppies, Solanum Wendlandi, and cut herbaceous flowers have been sent from Exmouth by Mr. W. GODFREY.

Messrs. CRIFFS, LTD., Tunbridge Wells, Kent,

have groups of well-coloured Japanese Maples and other foliage shrubs, interspersed with climbing varieties of Roses.

Messrs. HEATH & SON, Cheltenham, send Pelargoniums, Gloxinias, Orchids, and Carnations.

Messrs. J. GARAWAY & Co., Bristol, stage Roses, Lily-of-the-Valley, Schizanthus, &c.

Messrs. R. VEITCH & SON, Exeter, are showing a collection of shrubs, Alpine, herbaceous, and greenhouse plants, including Rehmannia angulata, Primula japonica, Hydrangeas, Lupins, Kalanchoe x kewensis, Gerbera Jamesoni, Kalmia latifolia, Enkianthus campanulatus, Incarvillea Delavayi, Cytisus purpureus, &c.

A superb collection of Rhododendrons is seen from the nursery of Messrs. JOHN WATERER & SONS, Bagshot, Surrey. The collection includes such standard varieties as Pink Pearl, Baron Schröder, Lady Eleanor Cathcart, Marquis of Waterford, F. B. Hayes, and B. W. Currie.

Messrs. COOLING & SONS, Bath, have a fine mixed collection of flowers, which includes many Roses and Carnations. Among the Roses are choice examples of Philadelphia Rambler, Lady Gay, Blush Rambler, Mrs. W. J. Grant, and Austrian Copper. The group also contains hardy Azaleas, Japanese Maples, tricoloured Geraniums, and the blue double-flowered Lobelia Kathleen Mallard.

Tuberous Begonias, both single and double-flowered, are well shown by Messrs. BLACKMORE & LANGDON, Twerton Hill Nursery, Bath.

Mr. CEDARS, the Hardy Plant Nursery, Wells, has staged a group of Clematis.

Messrs. W. CUTBUSH & SONS, Highgate, have a well-arranged collection of Roses, Carnations, Ericas, Richardia Elliotiana, Palms, &c.

Messrs. R. WALLACE & Co., Colchester, show Spiræas Queen Alexandra and Peach Blossom, Eremurus, Ostrowskia magnifica, Poppies, Lilies, Pyrethrums, and numerous other hardy plants.

Mr. WALTERS, Nurseryman, Bath, exhibits Roses, Clematis, perennial plants, and a pretty rose-coloured Mesembryanthemum with flowers 2½ inches across.

Mr. W. TRESEDER, The Nurseries, Cardiff, exhibits a collection of well-grown Conifers, Roses, &c.

Mrs. WILLIAMS, Bryn Glas (gr. Mr. J. Duff), has a group of well-grown herbaceous Calceolarias.

The Forestry exhibits comprise examples of pruning, showing good and bad methods, and the results; injuries caused by insects, fungus diseases, and wind and snow; sections of timber; photographs of forest and nursery planting; large trees, &c., creosoted wood, gates, fences, posts; seedling trees in various stages of growth, cut specimens of Conifers, rough and polished sections of timber, and many other things.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

MAY 16.—Committee present: E. Ashworth, Esq. (chairman), and Messrs. Sander, Ashton, Parker, Cypher, Stevens, Thompson, Thorp, P. Smith, H. H. Smith, Ward, Warburton, Cowan, Walmsley Duckworth, Williamson Rogers, Upjohn, and Weathers (hon. sec.).

This occasion was the annual general meeting of the society, and the report of the past year's proceedings showed the society to be in a good position. The honours of the session went to W. THOMPSON, Esq., of Stone, who gained the "Sander Cup" for the greatest number of points for the year. In the coming session, 1907-1908, trophies are to be competed for, viz. —W. Thompson, Esq., offers a Cup, value £15, for the highest points gained during the session; also a Cup, value £5, for the second highest, with money prizes for the growers. Messrs. Sander and Sons (who generously contributed last year's "Cup") offer a "Sander Cup" for Cypripediums, under certain easy conditions. Messrs. H. Low & Co. also offer a "Cup" for Lælias and Cattleyas (hybrids excluded).

The society is growing rapidly, and there is a great amount of enthusiasm amongst the members.

H. WHATELEY, Esq., Kenilworth, exhibited a few good varieties of Odontoglossum crispum, one of which, Odontoglossum crispum var. "Kenilworth Beauty," received an Award of Merit.

Mr. J. ROBSON, Altrincham, exhibited a number of good plants. A First-Class Certificate was awarded to *Cattleya* × *Thayeriana* var. *alba* in this group: the plant is a hybrid between *C. × intermedia* var. *alba* × *Cattleya Schroderae* var. *alba*. *Odontoglossum crispum* var. "Queen of Spain" was given an Award of Merit.

A similar award was also given to *Odontoglossum vexillarium* var. *Robsoniae* and to *Odontoglossum* × *Rolfæ* × *O. crispum* var. *Graireanum* in Mrs. ROBSON's collection.

Mr. W. SHACKLETON, Bradford, exhibited a good form of *Cypripedium niveum*, the plant receiving an Award of Merit.

Mr. JOHN STOTT, Radcliffe, sent a good plant of *Calanthe veratrifolia*.

E. ROGERSON, Esq., Manchester, was granted an Award of Merit for *Odontoglossum crispum* var. *Rogersonæ*, and a similar distinction was given to his *Odontoglossum* × *fascinator* var.

R. L. OVERTON, Esq., Neston, exhibited two good forms of *Lælia purpurata*.

Messrs. CYPHER & SONS, Cheltenham, gained an Award of Merit for *Cattleya Skinneri* var. *Fairy Queen*, a beautiful pale form of the type.

W. BOLTON, Esq., Warrington, staged a choice group of plants, for which a Silver Medal was awarded. A very beautiful variety of *Odontoglossum* × *loochristiense*, called *Boltoni*, in this exhibit, received an Award of Merit.

Messrs. LOW & CO. were given Awards of Merit for *Lælio-Cattleya* × *Dominiana*, Low's var., and for *Cattleya* × *Parthenia* var. *Prince of Wales*. P. W.

Obituary.

SIR DIETRICH BRANDIS.—The death of this distinguished scientist is announced, at Bonn. He was a son of Dr. C. A. Brandis, Professor of Philosophy at Bonn University, and was born in 1824. He received his education at the Universities of Copenhagen, Göttingen, and Bonn. In 1856 he was appointed Superintendent of Forests in Pegu; and he was Inspector-General of Forests to the Indian Government from 1864 to 1883. From 1887 to 1896 Mr. Brandis was closely associated with the forestry course in connection with Cooper's Hill. He was knighted in 1887.

F. Q. LANE.—We learn with much regret of the death on the 2nd inst. of Mr. Frederick Quincey Lane, head of the firm of Messrs. H. Lane and Son, of the Nurseries, Berkhamstead. Mr. Lane, who was a genial and much-respected member of the trade, was a son of the late Mr. John Edward Lane, who died in July, 1839, at the advanced age of 82 years, and grandson of the Mr. Henry Lane who founded the business, retired into private life about 1853, and died in July, 1865, at the ripe age of 88 years. Mr. Lane's brothers pre-deceased him, but he leaves some sons to carry on the nursery business, which for many years was specially famed for the high cultivation of Roses, Rhododendrons, Muscat Grapes, and fruit trees.

ENQUIRIES AND REPLIES.

MICE ATTACKING LILIES.—Can any reader say what is the best course of action to pursue? We have 15 to 20 kinds of Lilies growing in a wood, and field mice are destroying them at their flowering period entirely. They climb up the stalk, eat all the leaves, and bite off the shoot. Is it a common case? B. L.

ANSWERS TO CORRESPONDENTS.

ASSOCIATE OF THE ROYAL HORTICULTURAL SOCIETY: A. E. J. Apply to the secretary, Rev. W. Wilks, Royal Horticultural Hall, Vincent Square, Westminster.

CALCEOLARIAS MALFORMED: E. P. D. & Sons. The flowers exhibit peloria; it is a common occurrence for these flowers to assume such abnormal forms.

CATERPILLARS ATTACKING LIME-TREES: J. R. The leaves are attacked by the caterpillars of the "winter moth," *Cheimatobia brumata*. Your trees are of such a size probably as to render hand-picking impracticable, in which

case the only remedy you can adopt is spraying with some poisonous wash; the best is acetate of lead, 2½ ozs.; arsenate of soda, 1 oz., thoroughly dissolved and mixed in 10 gallons of water. Spray the trees next spring with the same mixture soon after the buds have opened, but if the trees are too large for effectual spraying, place early in October grease bands around the stems of the trees as is done in the case of Apple trees.

CLIMBING ROSES: J. H. Harm does not always result from the use of galvanised wires, if the shoots are not tied too tightly to them.

CUCUMBERS FAILING: F. H. The injury has been caused by an excess of water in the soil, aided, probably, by overfeeding with artificial fertilisers. There is no disease present due to fungi or insects.

DUTCH GARDEN: M. L. We know of no special work on this subject, but you will find all the general principles regulating the construction of such a garden in *The Art and Craft of Garden Making*, by Thomas Mawson, price 38s.; a less voluminous work is *The Book of Garden Design*, by Charles Thonger, price 2s. 9d. Both works can be obtained from our publishing department.

GOOSEBERRY PLANTS FAILING: Temple Hill. There is no fungus disease present; the cuttings was formed from wood that was too old for this purpose, and few if any roots have formed in consequence.

GRAPES SPOTTED: A. E. P. The berries are affected with the spot disease. See answer to H. C. in our last issue.

GRUBS DEVOURING PLANTS: W. R. P. The insects attacking your plants are specimens of the flattened snake millipede or "Galley worm," *Polydesmus complanatus*. They are very destructive pests and very difficult to destroy. Insecticides have not much effect upon them, but you might try watering the soil freely with a strong solution of nitrate of soda, or common salt. They can be trapped by burying small slices of Turnip, Mangel-wurzel, Potato, &c., just below the surface of the soil. A more certain method of destruction is to dress the land with gas lime and then to allow it to remain fallow for a period.

INSECT: E. B. The insect you send is by no means uncommon, and is a specimen of one of the Longicorn beetles, *Clytus* species. This beautifully-marked insect is often found on flowers, particularly members of the Umbelliferae. The grub lives in the wood of posts, palings, &c.

LEAN-TO FERNERY: Hodshill. The best arrangement possible in the circumstances would be to prepare a ground plan, showing an irregular pathway through the house in conjunction with bays of an informal character on each side. The pathway could terminate at 3 feet from the end farthest removed from the door or any convenient distance that may be desired. By adopting such bays or recesses a very considerable frontal surface would be available for planting, and in the lower ledges or pockets many of the small-growing species could be accommodated, while reserving the summit and the prominences formed by the bays for plants of larger growth. This arrangement if carried out in detail would necessitate the forming of a considerable number of pockets for the plants, as the sides or front portion would not be suitable for plants of the larger growing species. By so arranging two bays or recesses at the back portion, that the pathway will penetrate towards the wall, all the plants will be well under the control of the cultivator. We do not know whether you have decided upon the species you intend to cultivate, but upon this decision must depend to a large extent the size of the necessary pockets. In any case it is important that all pockets intended for plants should be charged with soil to their very base, otherwise the water might pass away without benefit to the plants. By arranging pockets with the stones, in place of using pots, the pockets could be filled with suitable soil as in potting, but it may be necessary to fix the stones together with cement to ensure stability. You could so arrange the larger pockets that they would constitute receivers for large pots, the latter to be quite hidden from view. Such arrangement would have its advantages when potting time

came round, and in that way any plant could be attended to at any time. Success may be obtained, however, from the planting-out method if this be rightly carried out. You do not say what kind of stone you propose using, but we suggest "tufa" unless you can get some weathered limestone in your own district.

LILAC LEAVES INJURED: C. E. No fungus is present; the injury has been caused by frost.

MELON PLANT INJURED: T. M. The brown spotting has been caused by scorching. Admit more air to the structure in which the plants are growing and keep the atmosphere rather less moist.

NAMES OF FRUITS: A. E. G. *Photinia japonica*; the Loquat or Japanese Quince.

NAMES OF PLANTS: R. O. Y. 1, *Odontoglossum Wallisii*; 2, *O. blandum*; 3, *Oncidium maculatum*; 4, *Ada aurantiaca*; 5, *Coelia Beneriana*; 6, *Brassia maculata*.—E. 1, *Heuchera sanguinea*; 2, *Anchusa italica*; 3, *Allium neapolitanum*; 4, *Spiraea Anthony Waterer*; 5, probably *Metrosideros floribunda*—send when in flower; 6, *Allium neapolitanum*.—Wolf. 1, *Spiraea confusa*; 2, *Olearia Haastii*; 3, *Taxus baccata* (Yew).—F. R. 1, *Pernettya mucronata*; 2, *Saxifraga umbrosa serratifolia*; 3, *Antennaria tomentosa*; 4, *Aubrietia Campbelli*; 5, *Scilla peruviana*; 6, *Begonia semperflorens gigantea*.—H. & Co. *Alyssum (König) maritimum*.—G. S. J. *Odontoglossum triumphans* and *Odontoglossum crispum*. The "Tea tree" *Lycium chinense*. We do not undertake to name varieties of Roses.—E. C. C. D. *Saxifraga granulata*, double-flowered variety.—C. W. *Cytisus racemosus*.—C. E. F. *Aerides falcatum*.—B. P. 1, *Berberis stenophylla*; 2, *Spiraea confusa*; 3, *Spiraea arizaeifolia*.—F. E. A. 1, *Cotoneaster frigida*; 2, *Ulmus campestris* var. *viminialis*; 3, *Cydonia (Mespilus) vulgaris*; 4, *Weigela rosea*.—C. P. *Lepidium Smithii*.—A. B. 1, *Iris germanica*; 2, *Scilla peruviana*; 3, *Asphodelus ramosus*; 4, *Phlox canadensis*; 5, *Veronica spicata*; 6, *Saxifraga hypnoides*.—D. R. 1, *Scilla peruviana*; 2, *Veronica gentianoides*.—M. 1, *Eriobotrya japonica*; 2, *Anthriscum liliastrium*; 3, *Jasminum revolutum*; 4, next week; 5, *Asphodelus ramosus*; 6, *Weigela hortensis rosea*.—J. C. B. *Schinus Molle* (Pepper-tree).—Z. Y. X. 1, *Akebia quinata*; 2, *Maurandya Barclayana*; 3, *Spiraea callosa*; 4, *Euphorbia Lathyris*.—J. S. A. *Pteris longifolia*; B. *Adiantum concinnum*.—Fresco. 1 and 2, *Cystopteris bulbifera*; 3, *Polypodium vulgare cambricum*; 4, *Lastrea spinulosa*; 5, *Cystopteris montana*; 6, *C. fragilis*. It is very difficult to name dried barren fronds of Ferns. Fresh fronds, both barren and fertile, should be sent whenever possible.—C. E. A. 1, *Saxifraga pyramidalis*; 2, *S. hypnoides*.—F. G. C. *Prunus (Cerasus) pseudo-Cerasus flore pleno* (double-flowered Cherry).—L. & Son. We cannot undertake to name varieties of Spanish Iris with certainty. The one you send may be *Avalanche*.

PEACH LEAVES INJURED: J. S. The brown markings are caused by the shot-hole fungus—*Cercospora circumscissa*. Burn all the fallen leaves and spray the trees with ammoniacal solution of copper carbonate at intervals.

PEACH MILDEW: H. W. The fruits are attacked by a fungus—*Oidium leucoconium*. Syringe the trees with a rose-red solution of permanganate of potash.

PELARGONIUMS: J. Mc. The plants have received some check. They will probably grow out of this condition later.

YELLOW WALLFLOWER: A. S. All the varieties of Wallflowers are fragrant; apply to a nursery firm who makes a speciality of these flowers.

WORMS ON STRAWBERRY LEAVES: B. H. M. The thread-like worms are a species of *Gordius*, a genus of Annelida. Their common name is hair eel.

THE COUNTRY GARDEN.

THE massing of tender plants into small and formal beds is falling more and more into disfavour. As patches of colour, we are bound to say such beds were well and good; but, fortunately, mere masses of bright colour arranged in heart, crescent, lozenge, or other forms are failing to satisfy those who are sufficiently interested in their flowers to require of them more than that they should supply mere displays of colour.

The beds are there; they must be filled. The orthodox bedding plants fill them with as brilliant a display as anything would produce. There is no gainsaying the first and second of these statements—the beds exist in most gardens, and they need filling; from the last, however, I dissent.

The gist of the matter is to find a treatment that shall make a practical and effective alternative to the old one, and I never saw the puzzle better solved than in an old country garden where the parterre—which dates from a singularly uninteresting period in the history of English garden- ing—was transformed into a particularly

beautiful Rose garden. For the larger and bolder beds it became necessary, or, at any rate, advisable, to run two or even three of the small conventional beds into one. Thus, at the corners, two small circles and one square were at each corner transformed into a simple effective bed that I can best describe as of kidney shape. There is a good deal to be said for this particular shape; if large enough, it is never assertive nor aggressive. It goes without saying that an alteration such as I am suggesting reduces the grass area to a certain extent, for I am speaking of beds cut in grass; but that is not necessarily to be regretted, especially as the whole character of the position changes with the use of Roses in the place of bedding material.

I have chosen this subject for the present article for two reasons. First, because if any such change is eventually to be made, the various considerations as to the position, size, shape of beds, &c.—so far as these have to be determined in relation to background and general setting—will be made far more easily and effectually in the mind, when the background and setting are clothed in their summer foliage, and the surrounding beds have their plants at their summer heights. We cannot afford to leave out considerations such as these when contemplating alterations—the surroundings of a position count for much. Secondly, I have chosen this subject because, if the Rose bushes are desired, we have in the immediate future the most favourable time for budding, or, if we desire specimens on their own roots, then for rooting cuttings. I know many never think of putting in cuttings until October, but I often find these early specimens root very quickly, and practically six months is thus saved, because cuttings put in during the late autumn frequently do not root until spring.

Strenuous efforts should be made to prolong the flowering season of the rock garden as long as possible. There is no other decorative feature that is so telling as this. It goes far to break the monotony of beds and borders. It is distinct, and it gives character. Too often the display is practically over when the Aubrietia, the Saxifragas, Alyssums and other brilliant spring-flowering plants have ceased to flower. We ought, as a matter of fact, to pay especial attention to planting sufficient subjects to make a really decorative effect in late July and throughout August. For glowing radiant colour I know nothing that I can recommend with greater confidence than *Potentilla nepalensis*. It is a host in itself; and, if I may say so, furnishes a wider space by far than it covers. *P. alpestris*, with yellow flowers, is valuable, and so also is *P. nitida grandiflora*, with rose-pink blossoms. Indeed, many of the rock-loving *Potentillas* may be made a distinct feature late in the summer.

For this same late season *Prunella Webbiana grandiflora* is remarkably showy, and intense in colouring, and it is wonderful how effective is even a small patch of colour that is vivid and brilliant over and above the majority of flowering plants in proximity to it. The late-flowering *Gentians* have this same excellent quality, that of possessing colours that remain effective for a very considerable distance. *G. arvernensis*, *G. purpurea*, and *G. septemfida* are all choice and beautiful subjects. I may add that all the plants

I have mentioned flower simultaneously. I keep a notebook to jot down the flowering time of plants. My notes for all these are dated August 3rd, and at that time most of them are at the height of their flowering, so that they, when used in conjunction, really make the rock garden almost as showy and effective as during the spring-time. *Practical Gardener*.

BOTANICAL WORKS OF THE LATE DR. MASTERS.

DR. MASTERS was a prolific writer in many branches of botany, beginning, like most of us, with the British Flora. The earliest article of which we find a record is "On the Arrangement of the Air-cells in Aquatic Plants," in *The Ashmolean Society's Proceedings*, 1853, vol. iii., pp. 16-19. This we have not seen, but it was followed by a note on Kentish plants (*Phytologist*, 1855, vol. i., p. 189), in which the following characteristic sentence relating to plant-life, occurs:—"Those who attach so much importance to the physical state of the soil, as determining the growth of certain plants, will perhaps explain how it is that the *Statice Limonium* grows so abundantly in two soils of such opposite degrees of consistency as the chalk in the cliffs about Dover and elsewhere, and the soft mud in which it thrives at Whitstable."

On leaving King's College, Dr. Masters went to Oxford in the capacity of Sub-Curator of the Fielding Herbarium, and during his residence in that city he actively investigated the flora of the neighbourhood, and drew up an analytical sketch, which was published by the Ashmolean Society in 1857. Although only filling an octavo sheet, this little essay was well received, and three pages were devoted to a notice of it in the *Phytologist*, 1857, vol. ii., p. 112. It is an epitome of interesting facts, and a note on *Ophrys apifera* merits reproduction here, although not immediately connected with the flora of Oxfordshire. It runs:—"Writing to my father on the subject of the Bee Orchis, G. Chichester Oxenden, Esq., of Broome Park, Kent, remarks: 'For forty years of my life a certain field on this estate was under the plough; after this it was laid down for grass; and the third year after it was thus laid down, there appeared in it at least a hundred Bee Orchises, more, in fact, than existed in a circuit of five miles round.'"

This was regarded as very extraordinary in those days, and difficult of explanation, but it is now known that seedling Orchids are by no means rare some seasons, and it may be assumed that the very small seed of the Bee Orchis was sown with the grass seed.

Dr. Masters had many special studies: among the earliest was vegetable teratology, and we find a contribution of his to this subject in the same volume of the *Phytologist*. This was succeeded by numerous articles on the same subject in various publications, and culminated in the appearance of his book, entitled *Vegetable Teratology*, in 1860. The continuation of the title, "An Account of the Principal Deviations from the Usual Construction of Plants," affords an idea of the nature of its contents. As a contemporary reviewer stated, it is a collection of facts rather than a statement of theories, differing in this respect from Moquin-Tandon's *Éléments de la Tératologie Végétale*, 1841, and Kirschleger's *Essai Historique de la Tératologie Végétale*, 1845. It was the first work of its kind, and it met with universal acceptance, and it is still unsurpassed in the English language. It was soon out of print, the author's calls in other directions preventing him from preparing another edition; but a German translation, with numerous additions and corrections by the

author, appeared in 1886. In following up the teratological work of Masters, we have got in advance of the march of events, and must now go back a little. His illustrious predecessor, as chief Editor of the *Gardeners' Chronicle*, John Lindley, died November 1, 1865, and Masters was at once appointed, one of his first duties being to write an account of his departed friend. We have only to turn to the pages of the *Chronicle* immediately following the event, to learn how fully and sympathetically he executed this sorrowful task. Then take succeeding leading articles, and we cannot but be impressed with the ability, sincerity, versatility, and open-mindedness of the writer. The following year, 1866, saw the great international exhibition; a great historical event in horticulture, which has not been surpassed in this country up to the present day. The amount of work, obligatory and voluntary, Masters accomplished in connection with the Botanical Conference and the Show is perhaps better known by the writer and Dr. Ed. Goetze, who assisted him in some of the literary and linguistic details, than by any other persons now living. It was almost night and day, and Sunday, too. It was he who edited the voluminous Report of the Proceedings, though his name does not appear on the title-page.

As the visitors' book shows, Masters worked two or three days a week in the Kew Herbarium as early as 1865, when he was engaged describing the Malvaceæ, Sterculiaceæ and the Tiliaceæ for Oliver's *Flora of Tropical Africa*, the first volume of which was completed in 1868. He also worked out the Samydaceæ, Loasaceæ, Turneraceæ and the Passifloraceæ for the second volume of the same work, which was published in 1871; and he subsequently elaborated practically the same natural orders for Hooker's *Flora of British India*, with the addition of the Olacaceæ.

(To be continued.)

ORCHID NOTES AND GLEANINGS.

ARPOPHYLLUM GIGANTEUM.

A fine inflorescence of this old Orchid, which in the days when prizes were given for 12 or 20 large specimen Orchids, often supplied one of the most beautiful plants in a collection, is sent by Mr. H. Haddon (gr. to J. J. Neale, Esq., Lynwood, Penarth), whose accompanying letter is worth quoting, as it explains the reason why this species often fails to flower in gardens. Mr. Haddon says: "The plant has been here for many years, but it never flowered until now. Last year I removed it to an unshaded corner of the cool-house, and it made fine pseudo-bulbs and leaves, and this year it produced four fine spikes similar to the one I send, and they have been in flower a long time."

The plant is a very robust grower, and will keep in good condition even in an atmosphere which is too warm and "close" to admit of its blooming. A good light and well-ventilated situation, however, are necessary to the production of the flowers. It is a native of Mexico and Guatemala, and was first introduced to the Chiswick Gardens of the Horticultural Society through Hartweg, in 1839. It is recorded that from October to March the plants in their native habitat are occasionally exposed to violent storms, during which the force of the wind is so great that a man can only with difficulty keep on his feet. The flower-spikes are produced from the tops of the pseudo-bulbs, are 10 inches or so in height, and bear densely-set purple and rose-coloured flowers, arranged in erect cylindrical racemes.

NEW SPECIES IN KEW BULLETIN.

The last issue of the *Kew Bulletin* contains the following "Decade of New Orchids," described by Mr. R. A. Rolfe.

FIG. 158.—GLADIOLUS ATRO-VIOLACEUS.

(For text see page 379.)

Bulbophyllum dichromum.—Allied to *B. fusco-purpureum* Wight. Flowers in a loose raceme of about 12. Colour bright yellow, with purple lip. An introduction by Messrs. Sander and Sons. Flowered at the Royal Botanic Gardens, Glasnevin.

Bulbophyllum tridentatum.—A rather large-growing species allied to *B. mandibulare*, but with narrow, elongated sepals. Dull yellowish-green and brownish-purple. Flowered with Messrs. Sander and Sons in May, 1902.

Calogyne Mooreana.—Flowers white, with yellow crest, and approaching *C. cristata*. Introduced by Messrs. Sander and Sons, and awarded a First-Class Certificate at the Royal Horticultural Society in December, 1906.

Calanthe burmanica.—Of the *C. veratrifolia* section, allied to *C. Cecilie*. Flowers mauve-purple, with yellow crest. Native of the Shan States, Burma. Flowered at Glasnevin, 1906.

Cymbidium pumilum.—A dwarf species allied to *C. ensifolium*. Introduced by Mr. Peter Barr through a Japanese nurseryman, and known to be indigenous in Yunnan.

Stauroopsis chinensis.—A Chinese species allied to *S. gigantea*. Not yet in cultivation.

Stauroopsis luchuensis.—Allied to *S. undulata* Benth., but has yellow flowers spotted with brown. From the Malay Archipelago.

Saccolabium Woodfordii.—Allied to *S. flexum*. Flowers pale vermilion, tipped with brown on the inside of lip. Native of the Solomon Islands.

Cleisostoma secundum.—Introduced by Messrs. Hugh Low & Co. from Burma, and flowered by them in 1890. Flowers rose-pink, with rose-purple front to the lip; racemes one-sided.

Disa Bakeri.—Allied to *D. Deckenii*, Rchb. f. Flowers pink. British East Africa, alt. 2,400 to 3,000 feet.

THE ALPINE GARDEN.

SOME HARDY PRIMULAS.

Primula marginata grandiflora.—Of the very numerous forms of *Primula marginata*, *grandiflora* is decidedly the best, not only because of its larger flowers, but also on account of their soft, yet bright and pleasing colour, which is difficult to describe, but may be called a shade of lilac-purple. The blooms, which are produced in a stout truss, are larger in size than those of any other variety of this species, and the plant itself grows well, although it does not increase rapidly. Many cultivators of hardy Primulas give all the species the same treatment, but there is the greatest difference between the requirements of, say, such a species as *P. marginata*, which is a rock-lover, and which should have a rather dry position, and *P. rosea*, which requires moisture. The plant under notice does well in my garden planted on a dry terrace in a rock-garden, and with a little calcareous matter about it, for the silvery margin of the leaf seems to become clearer and whiter when lime is present in the soil.

Primula rosea grandiflora.—There are several types of this lovely Himalayan species, and these differ greatly in value and in character. The variety named *grandiflora* shows considerable difference in the size and brightness of its flowers. The best I have seen I obtained from an English nursery some years ago as *P. rosea grandiflora*, and which has done very well with me. It is conspicuous for its dwarf habit, and good, compact truss of bright rose-coloured flowers. Two years ago I brought a single plant of some four or five crowns from my old garden to my new one, and I divided it during the early part of the summer, re-dividing it late the following autumn, and again last year. I have given away a few plants and have still a good group, which yielded some 60 inflorescences. It grows in my garden in a low bed, at the base of a portion of my rock garden, and where the surface water from an adjoining path soaks into the bed. The soil is composed of light loam, a

little sand, some old decayed turf, and a very little peat. I believe that this Himalayan Primrose requires frequent division at its roots, and that this treatment results in greater vigour and strength.

Primula capitellata.—Blooming beside *P. rosea grandiflora* in my garden is a good specimen of the comparatively scarce *P. capitellata*, not to be confused, of course, with *P. capitata*, a *Primula* of no great importance. *P. capitellata* has trusses of small flowers of a purple colour and pleasing green leaves, somewhat similar to those of *P. rosea*, but considerably larger. It has proved hardy in my garden for two years. This, according to Pax, is a member of the same section as that to which *P. rosea* belongs, and appears to flourish under the same conditions. It is a native of Armenia, Eastern Persia, and Afghanistan.

Primula involucreta.—This is another Himalayan species of much beauty, and which appears also to enjoy a moist position in a rather peaty compost, but one not absolutely laden with moisture or continually in water. It is placed in the same section by Pax in his monograph as *P. farinosa* and *P. scotica*, but it is quite a different plant from a garden standpoint. Its leaves are light green, and the stem is fleshy. The creamy-white flowers with a yellow eye are produced in clusters. The plant is quite hardy with me, but if it is not top-dressed with a little soil in autumn some little care is necessary to prevent its loss in winter. Its height is about 6 inches.

Primula farinosa.—The exquisite Bird's Eye Primrose, although a native of this country, presents many difficulties in its culture. Last year I saw it in its native habitat on the steep, moist, grassy banks sloping to a mountain lake, and I noticed there were few large clumps, but many scattered plants, probably seedlings, which points to the fact that its period of existence is short even in a wild state. In a garden it is almost impossible to afford the plant the conditions it enjoys in nature, but it can be so grown that a plant of some other kind will shelter its roots from the summer's sun, which on the mountains is done by the grass. Chickweed has been found excellent for this purpose, and I am also trying *Saxifraga cymbalaria*, a purely surface-rooting plant, with the same object. S. Arnott.

GLADIOLUS ATRO-VIOLEACEUS

(Boissier).

This little *Gladiolus* from the plains of Syria has been cultivated in botanic gardens for a considerable time. The earliest reference to it I can trace is in the first Hand-list of Herbaceous Plants published at Kew in 1895, wherein *G. aleppicus*, also of Boissier, is cited as synonymous.

It is a pretty plant of comparatively easy culture that one can recommend for the bulb-border, the rock-garden, or for pot culture in the cool house. It has the slender growth of *G. Colvillei*, producing arching spikes 18 inches in height that carry on an average six flowers each, and these measure 2 inches across the expanded flower.

The upper petals are the broadest, and they are somewhat hooded; in colour they are rich violet. The lower or lip petals are faintly pencilled with white or yellow on a violet ground colour. I have had the plant under cultivation for two years, but have not tested its degree of hardiness, but that it grows wild intermingled with the Turkish Corn Flag (*G. byzantinus*) is sufficient to prove that it will be hardy in this climate provided it is afforded a light, warm soil in which to grow. It flowers in May, but one can force it into flower as early as March by gradually raising the temperature of the house in which it is grown.

The species received the R.H.S. Award of Merit when shown by Messrs. R. Wallace & Co., on May 14 last. J. B. M.

TWO NEGLECTED FRUIT PESTS

In my last article (see p. 309) I referred to the fruit pests of the season as noticed in my own plantations; but it seems desirable to refer more in detail to two which are commonly neglected, especially as the damage caused by them is in evidence at the time of writing. One is an insect, and the other a fungus pest. These are the larvæ of the pith moth (*Laverna atra*) and "brown rot" of fruit (*Monilia*, or, as it is now more often styled, *Sclerotinia*) fructigena. The most noticeable symptom of both attacks at this period of the season is the same on off-hand inspection, consisting of the drooping and ultimate withering of fruit spurs and ends of shoots. But if these are dissected, in those attacked by the pith moth a small reddish-brown caterpillar will be found, while the shoots and spurs destroyed by "brown rot" are simply rotten. The withering is generally attributed to frost, though the real causes are more easily identified than they were a few years ago.

In 1898, the late Miss Ormerod said that the attack of the pith moth caterpillar appeared to be very seldom noticed in this country, two reports on it in 1898 being the first she had received. Even in his report on "Orchard and Bush Fruit Pests in 1906," Professor Theobald stated that he had received only one reference to the pith moth, and he added that "Messrs. Newstead, Warburton, and Collinge do not seem to record it in any of their reports." I venture to believe that the reason of this freedom from notice is, not that the pest is not widely prevalent, but that its damage is generally attributed to frost. Certainly it is more the rule than the exception to find many withered trusses of fruit blossom and ends of shoots, including laterals, at the end of May or early in June in any plantation of Apples; and, if this damage is not the result of brown rot or canker, I am persuaded that proper inspection would prove it to be usually attributable to the pith moth.

Let any grower not familiar with the injuries caused by this pest cut off a few withered ends of shoots or fruit spurs, and break or cut them in halves near the tips. If he finds them hollow inside he will only have to pursue the borings made by the caterpillars to find them inside. I have recently cut some thousands of withered ends of shoots and trusses of blossom off trees in a plantation of 5½ acres, and in nearly all that were examined and that were not affected with brown rot, I found the pith moth caterpillar. I cannot suppose that what is so extensive in my orchard is uncommon elsewhere. Besides, I have found the pest only too prevalent in other people's plantations. To some extent, it is to be found in dying buds on other parts of branches than the ends or fruit spurs, if they are cut or scraped off. It is of the utmost importance to cut off and burn the affected parts without delay. The caterpillar will shortly develop into a chrysalis, from which in July the moth will emerge to deposit its eggs on the trees.

As an example of a pest escaping observation for years, or possibly generations after it has become common, the case of the bud moth (*Hedya ocellana*) may be mentioned. In Miss Ormerod's *Handbook of Insects Injurious to Orchard and Bush Fruits*, it is not even named, and when shortly after or before the publication of that work I sent her specimens, she had had some from only one other correspondent. At the present time this pest is known to be widely prevalent. But so it was at the earlier period, as I found it in every fruit plantation which I visited at the time, although not one of the occupiers knew anything about it.

As to "brown rot," it is only the symptoms of the disease in its present stage that are not commonly recognised, as all growers must be familiar with its attack upon the fruit, on which it appears in brown patches, or at least with the mummified Apples which often hang on the trees till those of another season are partly grown. The attack on the leaves resembles that of scab.

Mr. George Misse, in his *Text-book of Plant Diseases*, says but little about the attack of "brown rot" on shoots and fruit spurs, but gives a good illustration of an affected Apple, enabling any reader to distinguish it from scab. He states that the mycelium of the fungus is not permanent in any part of the host, so that every

spring the trees are perfectly free from the disease, and would remain so if not inoculated by spores derived from the affected fruit of the previous season—meaning, it is to be supposed, the mummified fruit. In that case my care in cutting off affected fruit spurs and ends of shoots and burning them may have been superfluous, but, without examination, it cannot be determined whether the withering is due to "brown rot" or to the pith moth caterpillar. Besides, the trusses of withered blossom, and in

As a rule, the trees badly affected with "brown rot" are nearly or quite free from pith moth attack, or the evidence of it. Possibly this is because the rotting result of "brown rot" attack has starved any caterpillars in the diseased shoots or fruit spurs. But I do not find the boring of a caterpillar in any spur withered by "brown rot."

Both pests are extremely and permanently damaging to the trees which they attack, especially in the destruction of fruit spurs. The

described as heroic. Fruit growers have some other work than spraying, though this fact does not seem to be recognised by their scientific advisers. *A Working Grower.*

ROSE "PARADISE."

LIKE many other recent varieties of rambler Roses, the one under notice has been introduced here from America. It was raised by Mr. M. H.

FIG. 159.—ROSE "PARADISE," A NEW RAMBLING VARIETY RAISED IN AMERICA: COLOUR OF FLOWERS PINK AND WHITE.

some cases the fruit spurs, quite down to their bases are rotten, while the rottenness of many of these has penetrated into the branches. It must be important, then, to cut off the affected spurs before their rottenness has gone so low down.

As the result of this disastrously wet season, "brown rot" has developed to an extent never known before in my plantations. It was recently showing very extensively among Apple trees, and to a less extent among Plum and Cherry trees, now cleared of withered parts.

only remedy for the pith moth known to be effective is that of cutting off and burning the parts of a tree attacked by it. As to "brown rot," Mr. Massee recommends, besides the burning of all affected fruit, the drenching of trees early in the spring (before the buds expand) with a solution of sulphate of iron, and, after the buds have expanded, spraying at intervals of ten days with dilute Bordeaux mixture. If he means up to the time when the fruit is mature, or nearly so, the remedy must be

Walsh, Wood's Hole, Massachusetts, and the illustration at fig. 159 has been reproduced from a photograph obtained from the original plant. It is described as a hybrid from *Rosa Wichuraiana*, having single flowers which measure 4 inches in diameter, the petals recurving somewhat when fully expanded. The petals are pink at the margin, the larger portion of the base being creamy-white, whilst the centre of the flower is ornamented by the bright yellow anthers. The variety is already in cultivation in some English nurseries.

TREES AND SHRUBS.

VIBURNUM UTILE.*

THIS new species was recently in flower in the nursery of Messrs. James Veitch & Sons at Coombe Road, Kingston Hill. It was raised from seed collected by E. H. Wilson in Central China, where it is abundant on exposed cliffs in the neighbourhood of Ichang and on northern mountains.

Specimens had previously been collected by Thomas Walters, of the British Consular Service, by General Mesny, Dr. Augustine Henry and others, but prior to their introduction by Wilson, seeds had not been available in this country.

The plant at Coombe Wood is a neat shrub about 4 feet high, with spreading branches clothed with glossy green leaves and numerous cymes of pure white flowers, which latter suggest those of the familiar *Viburnum Tinus*, but they are pure white and the individual florets are larger. The stems are covered with a stellate tomentum when young, but become glabrous when mature, and are said to be used by the Chinese as pipe stems. The leaves are shortly petiolate, thick, lanceolate-oblong or ovate lanceolate, 1 to 1½ inch long by ½ to 1 inch broad, obtuse with an entire margin; the upper surface is glabrous and shining, the lower is covered with a whitish tomentum. The flowers are produced in dense, almost hemispherical corymbose cymes about 3 inches across at the apices of the numerous small branches; the florets are about ½ inch in diameter, campanulate, with rounded and spreading lobes; the short stamens are exerted.

It is an extremely floriferous species, the small plant under notice bearing no fewer than 90 trusses of bloom. No protection has been afforded the plants at Coombe Wood; they are growing in open, exposed positions, so one may conclude it is quite hardy. The glossy leaves, pure white flowers, floriferousness and neat appearance of this shrub will undoubtedly gain for it many admirers. It is a desirable addition to hardy spring-flowering shrubs. *H. Spooner.*

THE DOUGLAS FIR AND ITS VARIETIES.

THERE is no doubt that, if given the proper conditions, the Douglas Fir (*Pseudotsuga Douglasii*) can be more quickly and profitably grown as a timber tree than some of the other forest trees so commonly planted. That it is beginning to find favour in the eyes of the planter is proved by the fact that there is an ever-increasing demand for young Douglas Firs for planting. Some idea of its value is shown by the following extract, referring to a visit to the Durris estate, Lower Deeside, from the *Transactions of the English Arboricultural Society*, Vol. VI., part I., p. 16: "The Douglas Fir of Oregon takes precedence of all other exotic deciduous and evergreen trees and shrubs, and, owing to its free growth, freedom from disease, and wonderful adaptability to a wide range of soils, sub-soils, and elevations, has proved to be a valuable asset to our limited number of commercial timber-trees." Again, on p. 18: "A sawmill was seen at work, where a trunk of Douglas Fir was split up, revealing the remarkable growth of 14 inches of red or hard wood [the serviceable part] in an 18-inch deal."

The value of any timber depends to a great extent upon the quickness with which it can be produced; the proportion it contains of heart-wood to sap-wood; the uses to which the wood can be applied; and the ease with which it can be worked. The Douglas Fir is valuable from all these standpoints: it is a fast grower, eclipsing the Silver Fir (*Abies pectinata*) in this

respect, and this is admirably shown by a photograph of a section of each which may be seen in the No. 3 Museum at Kew. The two trees from which the sections were taken were grown in Ireland on the same kind of soil and under the same conditions of climate. Their age when cut down was about 22 years, and the Douglas Fir was 19½ inches in diameter to the 10½ inches of the Silver Fir. The latter is a quick-growing tree, but the former produced nearly twice as much timber in the same time. The proportion of heart-wood in the Douglas Fir is unusually large, as far as can be ascertained from trees that have been cut in this country, and in addition it is said to be "fine-grained, elastic, strong, heavy, free from knots, very durable, and not liable to warp or split." It is easy to work, takes a high polish, and has a very handsome appearance. Freedom from knots is a great desideratum in timber, as they render wood harder to work, and detract from its appearance and strength.

SOIL AND CLIMATE.

As stated, the Douglas Fir can be grown on almost any soil, and at various elevations, so that it may be said to be suited to practically any part of the British Isles. In growing trees for timber, the character of the sub-soil is of more importance than that of the top-soil, but the Douglas Fir has been grown well on gravel, clay, and practically every sub-soil to be found in the kingdom, with the exception of chalk, and even with regard to calcareous soils it is an open question whether it will succeed or not. In places where the chalk forms the bulk of the sub-soil, and with only a thin layer of humus on the top, the Douglas Fir would probably be unable to succeed, but where it could get through a comparatively narrow calcareous layer into the gravel or clay beneath, it would probably thrive. This question is, however, one which needs experimental planting to decide.

It has occasionally been found that this Fir will make good growth for a few years, and then become stunted and thin for a while, but finally grow freely again. This is due to the presence of an unbroken sub-soil or pan of a hard nature, and one that the roots cannot quickly penetrate, but once they have bored through it they commence to make strong and healthy growth again. If the top-soil is thin and poor, some of the trees may die during a dry summer through lack of moisture at the roots. Where this is the case a little labour expended in breaking the sub-soil when planting will be of benefit. The fact of ground being poor and stony need not deter foresters from planting the Douglas Fir, as this tree will thrive provided it can obtain a sufficiency of moisture. A damp, stagnant soil, however, is fatal to success, a well-drained ground being absolutely essential to the plant's well-being.

The above remarks apply to the so-called Douglas Fir of Oregon, but which is found from Oregon northwards on the western side of North America, both on the hills and in the valleys, where it is stated to attain upwards of 250 feet in height with a diameter of 12 feet at the base. (The largest specimens in this country are somewhat less than half this size.) Being spread over a large extent of country and at different elevations, it is naturally variable in its habit of growth, though not to the extent that might be imagined. If my memory serves me rightly, Professor Sargent found plants only about 3 feet in height on the hill-tops, but whose concentric rings showed them to be about a hundred years old.

THE TYPICAL DOUGLAS FIR

is a tall tree pyramidal in shape in a young state, but becoming more conical with age, with loose, open branches, borne horizontally or

slightly pointing upwards, and very small-wooded in proportion to the trunk that bears them. The leaves are about one inch or so in length, arranged all round the stems, soft to the touch, of a bright green shade above, and marked beneath with two silvery lines. The cones are 3 inches to 4 inches in length, pendent, and they ripen in the first year. The scales are persistent, and each one has a three-lobed bract attached.

VARIETIES.

There are some ten or a dozen varieties that have been named; the following vary but little from the type:—Var. *elegans*, var. *macrocarpa*, var. *Pattoniana*, var. *revoluta*, var. *Stairii*, and var. *taxifolia*. These kinds differ but slightly in habit and foliage, and considerably more variation can be found in a batch of young seedlings, if one studied every slight difference, than there is between these named varieties and the type. The differences amongst young plants consist chiefly in their rate and mode of growth, the typical plant being loose-branched and fast-growing; others are denser and sturdier, while others again are slow-growing and have varying foliage. Forms are also to be noted in which the branches assume a fastigate habit, but practically all these differences disappear with age, with the possible exception of a few dwarf-growing plants.

THE COLORADO DOUGLAS FIR

(P. D. var. *glauca*).

This variety is fairly well known, and has attained some popularity of late years on account of it being recommended as a timber-tree, and also as being hardier than the type. There is, however, no justification for this latter assumption; it is of comparatively slow growth when compared with the Douglas Fir, and it is certainly no hardier. It succeeds in certain parts of the country and yields serviceable timber, but the type grows better in the same time, and is preferable for timber purposes. As a specimen tree for the park or garden, P. D. var. *glauca* is to be recommended, the habit being pyramidal without excessive formality, and the foliage being of a glaucous-blue tint, which becomes deeper and better as the tree gets older. The leaves are 1 inch to 1½ inches in length, rather stiffer and harsher to the touch than those of the type; sometimes curved, but more often pointing forward towards the growing point.

There is a weeping form called var. *glauca pendula*, but it is not of much value, being an irregular-growing tree, with semi-pendulous branches. The weeping Douglas Fir (P. D. var. *pendula*) is a quaint tree with the branches hanging straight down the stem; a well-grown specimen has a picturesque effect in the garden. P. D. var. *nana* is a dense-growing little plant, attaining about 3 feet to 4 feet in height and with foliage like that of the type. P. D. var. *brevifolia* has leaves less than half-an-inch long that are clustered all over the stems, giving the plant a strong resemblance at the first glance to *Tsuga Sieboldi*.

DISEASES AND INSECT PESTS, &c.

The Douglas Fir is not affected by any fungus disease, whilst it is rarely attacked by insect pests, such as scale, &c. It is also free from the attacks of squirrels, so far as I have been able to see and hear.

In conclusion, the common Douglas Fir can be recommended for timber or as a large ornamental tree; the Colorado Douglas Fir is of ornamental value only; while the other varieties have a certain interest as showing the extent of variation from the type. *J. Clark, Bagshot, Surrey.*

**Viburnum* (*Tinus*) *utile*, Hemsley. *Index Flora Sinensis*, vol. i., p. 866.

THE PROPAGATOR.

LEAVES EMPLOYED AS CUTTINGS.

IN regard to this method of plant propagation, no certain period of the year can be named in which it can be best carried out. The right condition of the leaves of the various species differ in accordance with the treatment of the parent plants. The propagator who is unacquainted with the peculiarities of the plant he desires to increase must find out the most suitable time by experiment; but usually it will be found that a leaf-cutting will make roots more readily and be less liable to decay if used when fully developed and approaching maturity. Leaf-cuttings should be handled with care so as not to bruise them. Some plants possess leaves which will form roots wherever the midrib is cut across, each bit making a plant. Such are Gloxinias, many Begonias, *Rochea falcata*, *Cotyledon*, *Bryophyllum*, *Peperomia*,

are the first to show these close to the base of the midrib.

For the proper directions for the propagation of Carnations, Pinks, Azaleas, Kalmias, Rhododendrons, *Tabernaemontanas* and *Allamandas*, the reader may refer to the article on propagation in the *Gardeners' Chronicle*, June 23, 1906, p. 397.

PROPAGATION BY MEANS OF EYES (BUDS).

This method is practised with such plants as possess large leaves, hard wood, and large, strong buds. The buds must be chosen from one or two-years-old wood, and each should have a healthy leaf attached. The shoot with a good bud must be cut through six or eight lines above and below the bud, and the wood cut away, so that the pith is got rid of, and the wood beneath the bud reduced in thickness to two lines. The buds so prepared must be placed in the usual manner

being furnished with a few rootlets. The method employed may be cleft or side grafting, and after tying in the scion the point of union should be coated with grafting-wax applied in a lukewarm state. After the grafting process, pot them up and place them in a moist atmosphere over a bottom heat of 80° to 85° Fahr.

BUDDING.

The present is a good time for budding Hollies, Roses, Jasmines, Aucubas, &c. It is said that the Banksian Rose forms the best stock for the Marechal Niel Rose. F. M.

CHOISYA TERNATA.

Our illustration represents this fragrant white-flowered, Rutaceous shrub from Mexico, as it is at present in bloom at the front of the dwelling-house in the charming garden of W. A. Bilney, Esq., Fir Grange, Weybridge Heath, and which annually produces its show of fragrant blooms there, and in many other gardens in Great Britain. Although known in this country for many years past, it will be within the memory of many gardeners that the species was first cultivated as a stove shrub. The flowers were recommended as a good substitute for Orange blossom, for which purpose they have often been used. The species never appeared at its best until the plants were grown as hardy shrubs, and in such conditions its bright green leaves render it effective even when the plant is not in bloom.

THE ROSARY.

RAMBLER ROSES.

RAMBLER, *Wichuraiana*, and *Penzance* Roses will all submit to gentle forcing, and with care can be had in flower very early in the year, but they must not be subjected to excessive heat, for this will cause their petals to lose much of their colour, and the blooms will be pale in consequence. The plants should be induced to form a good root-system, which should quite fill the pots, and when they are introduced to heat it should be applied gradually, and not until they are accustomed to their new conditions should the temperature be greatly raised. They should be plunged in an old hot-bed where just sufficient heat is provided to start root action. As soon as the new growths develop they should be carefully tied and trained so that the stake or other support will be completely hidden, but when this is accomplished the growths may be allowed to hang loosely and thus show off their blossoms to advantage. Keep the foliage clean by frequent syringings and fumigations, for good foliage enhances the beauty of the flowers. The plants should receive some stimulant as soon as the flower-buds show, but if they possess a weakly root-system and cannot assimilate manures, feeding should be left alone.

Roses on their own roots will force well and will continually increase in size if the requisite attention be given at the time of potting. Roses may be propagated from cuttings of young wood or from ripened shoots in the late summer, but by rooting cuttings of the young wood a season is gained. The following list of varieties of climbing Roses will all submit to forcing:—Dorothy Perkins, Meg Merrilies, Hiawatha, Lady Gay, Crimson Rambler, Mrs. F. W. Flight, and Queen Alexandra. All these are good growers, and can be had almost any size in three years from the time of inserting the cutting.

Rambling Roses trained on arches, tripods, old trees, &c., in the open, have a delightful effect in summer time. Amongst some of the

[Photo by John Gregory.]

FIG. 160.—CHOISYA TERNATA IN MR. BILNEY'S GARDEN AT FIR GRANGE, WEYBRIDGE.

and *Achimenes*. The medium in which the leaf-cutting should be set may be sandy soil, finely powdered brick, or pure sand, the more readily decaying subjects being placed in the brick or sand. The propagator should take care to bring the base of the midrib of a leaf-cutting under the surface of the material, and in the case of a leaf cut in several places to lay it on the material, securing it with small hooks at the several incisions in order to bring the midrib at these points close to the sand, &c.

When roots have been made, the plants should be gradually inured to the air of the glasshouse in which they will have to live, and receive the same treatment as that afforded shoot cuttings.

Theophrastas may likewise be increased by means of leaf-cuttings, cutting these in half, sticking both pieces in the soil, and preferably under a bell glass or in a close case with a bottom heat of 80° Fahr. The first shoot arises from the callus-joint just above the roots, which

in small pans of sandy soil covered with a layer of sand, so that the "eyes" rest on the soil, and are then covered about one-tenth of an inch with sand, pressing them firmly and securing the leaves to little stakes, so that the "eyes" cannot shift. They are treated in the manner usual with ordinary cuttings, and must be kept in a moderately moist condition. The following plants may be thus treated: *Pyrus*, *Wistaria*, *Hydrangea*, *Camellia*, *Clethra*, *Magnolia fuscata*, *Pittosporum*, *Vitis*, *Citrus*, *Rosa*, *Chimonanthus*, *Dracæna*, and others.

The corms of *Caladiums* may be cut into as many pieces as there are buds on the corm, and similarly treated.

GRAFTING.

There are various greenhouse and stove subjects which may be grafted at this season—*Aralias*, *Ficus*, *Begonias*—on thick pieces of the roots of the same or allied species, the roots

best varieties for this purpose, with their colours, are *Rosa sinica* anemone (pink), *Aglaia* (yellow), *Dorothy Perkins* (soft pink, a very robust grower), *Annie de Geierstein* (a fine shade of red, one of the best climbing Roses), *Carmine Pillar* (rosy-carmine), *Crimson Rambler*, *Helene* (a seedling from *Crimson Rambler*, with petals a sulphur-yellow colour tinted with rose-violet). The flowers of "*Helene*" are large and double, and as many as 30 to 50 are developed on a single stem; *Alister Stella Gray* (straw-yellow), *Euphrosyne* (pink), *Lord Penzance* (fawn), *Lady Penzance* (copper), *Meg Merrilies* (crimson), *Hiawatha* (scarlet with yellow centre), *Leuchtstern* (bright rose with an attractive white "eye"), *Lady Gay* (deep rose-pink), *Stella*, *May Queen*, *multiflora*, *Reine Olga de Wurtemberg* (vivid red, with lovely foliage), *Thalia* (white), *Una* (one of the finest of all the white varieties), *Rosa sericea* (white), *Queen Alexandra* (rose-pink), *Manda's Triumph* (white and very sweet scented), and *Electra* (yellow buds, changing to a paler shade in the older flowers).

The roots of pillar Roses should be covered

does service in this way. Two other *Polypodiums*, which are somewhat of the same habit, and which also might be put to the same use, are *P. piloselloides*, a native of high elevations, and *P. loriceum*, which inhabits an intermediate position—neither so low down as *P. vacciniifolium* nor as high up as *P. piloselloides*. The three species are found here.

CEDRELA ODORATA L.
(The West Indian Cedar.)

THERE is at the present time a brisk local demand for the limited number of these trees found growing here.

I am informed the few that do exist on the island—where doubtless they were introduced and planted a long time ago, as it is questionable whether the species really belongs to the native flora of Grenada—have been bought up by a local merchant, some having already been felled and carted into town for shipment to England. During the tree's flowering period, which occurs about the middle of the year, a peculiar and strong-smelling odour pervades the air, and

THE FIG (*FICUS CARICA*) IN GRENADA.

It is unusual to hear of a Fig tree producing fruits in abundance on this island, but at Mount St. Ervans, the Rev R. J. C. Wolseley, the Roman Catholic priest of St. Andrew's parish, has succeeded in establishing a tree after a great deal of trouble, and in fruiting it; the fruits being of large size and of first-class quality. The name Fig, or Figue, is given, generally, in the island to the different kinds of Bananas, which, of course, belong to a very different class of plants.

PANICUM FLAVESCENS.

I HAVE noticed that when basic superphosphate has been applied in Cocoa fields in Grenada this grass springs up spontaneously, and to such an extent, that it suggests at once the question as to what has caused so much of one kind of grass to grow to the exclusion of nearly all other weeds. Going through an estate not long ago, one saw at a glance, by the presence of this *Panicum*, where this manure had been put down a few months previously.

POLYTRIAS PREMORSA IN GRENADA.

IN the parish of St. George this grass has become established in some of the pastures and along the waysides. Swards appear red at the time of flowering, and then the contrast to the surrounding greenery is very marked.

It forms a soft bottom, as well as being a fodder grass of considerable value, for I notice that animals feed upon it with much apparent relish.

Professor Urban informs me that it is only indigenous in Java, near the sea, and is naturalised in the Botanic Gardens at Singapore. How then did it find its way to this island? From enquiries made on the spot, I am unable to say, but it has been noticed for at least 25 years, which would be before the Botanic Station was started here. Large patches of it occur in the Richmond Hill district.

Considering that it makes a thick turf, I should be inclined to recommend it for use on lawns and pastures in the tropics. *W. E. Broadway, The Plant and Seed Nurseries, Grenada.*

PHLOX SUBULATA LILACINA.

Phlox subulata, the Moss Pink, is a valuable subject for the rock-garden or for places it is desired to cover completely with greenery. It forms a mat-like growth, which, at this season of the year, is almost hidden with numerous star-shaped flowers. It succeeds well on a dry bank, over which it will ramble and flower profusely. The species is a native of Virginia, and since its introduction many varieties have originated, some having white flowers and others flowers of various shades of pink and mauve, &c. *P. s. lilacina* is shown in flower in the illustration at fig. 161.

[Photo by F. Mason Coad.]

FIG. 161.—PHLOX SUBULATA LILACINA GROWING ON A ROCKERY.

with a good mulching of manure several times during the season, and the foliage should be kept clean and healthy. *W. A. Cook, Leonardslee Gardens.*

COLONIAL NOTES.

GRENADA, W.I.

POLYPODIUM VACCINIIFOLIUM L. & F.

WHERE a bare surface exists which requires screening, such as a wall, or where a tree trunk might be beautified by a covering of some plant growth, this *Polypody* can be recommended.

The thick, reddish-brown rhizomes grow in masses or in clumps together, which renders easy the accomplishment of such a covering. The leaves are not conspicuous for their size as both fertile and barren ones are very small when compared with those of many of the other species of the same genus. In Grenada it thrives at low elevations in the open, as well as in partial shade. It is a pleasing change from the stereotyped *Ficus stipulata* (*F. repens*), that usually

this is especially noticeable at night-time. The timber furnishes a fine cabinet wood, and it is, in addition, very fragrant.

Advertisements appear in the newspapers of the neighbouring island of Trinidad for "Cedar logs at the highest market rates."

A DOUBLE WHITE-FLOWERING HIBISCUS.

THIS is a very uncommon plant in Grenada. About two years ago I accidentally came across a solitary weakly-looking plant in a private garden. When I returned a little later on, I was disappointed to hear that it had died, but I was not surprised, owing to its sickly condition. Quite recently I saw a fine healthy plant some 10 feet high of this *Hibiscus* in a poor man's garden, and the owner informed me it was known as the "*Halifax*." From it I obtained cuttings, several of which are now flowering, although the plants are not more than from 8 inches to a foot in height. Its sturdy habit, and the purity of its large white flowers, which are produced in profusion, render it a most useful garden subject.

RHODODENDRON SHOW IN THE ROYAL BOTANIC GARDENS.

—Messrs. JOHN WATERER & SONS, LTD., Bagshot, opened their annual exhibition of *Rhododendrons* in the Royal Botanic Society's Gardens, Regent Park, on Monday last. The area enclosed within the tent is one-third of an acre, and the effect is brilliant. About 2,000 *Rhododendrons* of various sizes from 2 feet to 10 feet or more in height are used in making up the various beds, which are laid out in much the same way as they would be planted in private gardens. From 200 to 300 different varieties are shown, amongst them being the best of the older kinds and also most of the novelties of merit, such as *Pink Pearl*, *Mrs. Stirling*, *Gomer Waterer*, and others.

NOTES FROM ISLEWORTH. FRUIT PROSPECTS.

GROWERS in W. Middlesex will again experience a somewhat disappointing season in the orchard, the more disappointing as the promise at the end of April was so exceptionally good. The great fluctuations of temperature during May caused the trees to shed half their crop, and it now seems as though the only crop above the average will be that of cooking Plums. Apples generally will yield about half a crop, Pears about one-third of a crop, and Plums three-quarters.

On the contrary, all small fruits promise well, and Black Currants will be exceptionally plentiful. There is a record set of Apricots on wall trees, and a very fine show of Peaches, Nectarines, and Morello Cherries on similar trees. The season will be a good one for those few who grow Apricots, Peaches and Nectarines as bush trees, for this year remunerative crops should be secured, and this does not occur more than once in about eight years.

There will be a great shortage of the best class of dessert Pears, Apples, and Plums.

Wall fruit is not included in the following estimate, nor trees that have been protected. The figure 100 represents the maximum crop that should be left on the trees after thinning, so that the figure 70 may be taken as about the average crop over a series of years.

Apples.—Cooking varieties, 75; (Prince Albert, 75); dessert varieties, 25; (Cox's Orange Pippin, 15; Ribston Pippin, 50); various dessert sorts, 50.

Pears.—Dessert varieties, 12; (Marie Louise, 10; Doyenne du Comice, 15); various dessert sorts, 55; cooking varieties, 40.

Plums.—Cooking varieties, 160; Damsons (results still doubtful), 20; (Coe's Golden Drop, 15); various dessert sorts, 15 to 70; Greengages, 100; Jefferson's, doubtful.

Cherries.—Sweet sorts, 55.

Apricots.—Moor Park, 55.

Peaches and Nectarines.—80.

A. Worsley, Isleworth.

FRUIT REGISTER.

APFEL AUS LUNOW.

LONG-KEEPING Apples are not too numerous, and one that is edible from the month of January till August is an acquisition of the first order. The variety is given in the German name as above (Apple from Lunow), and is highly spoken of by Hrn. BRETT-SCHNEIDER in the *Gartenflora* for May 1 as a pleasant fruit for the dessert. The blossom is large, 5 cm. in diameter, with shell-like petals, which do not touch each other; strong fruit buds with long, fleshy envelopes; petals pale pink with darker veins. The diameter of the Calville-like fruit is about 10 cm., the height 9.5 cm.; the shape conical, the greatest circumference being about one-third distant from the stalk, which is set in a deep, smooth cavity. Towards the eye the diameter decreases sharply. The fruit is ribbed smoothly and possesses a regular form. The eye pointed and closed sits in a deep basin, which is ribbed. Stalk is short, woody, sunk in a wide and deep depression, above which it does not rise. The rind is fine, slightly shining, ground colour light straw-yellow; on the sunny side of a light carmine tint, with darker patches and broad stripes running over it. Small, dark points are visible over the entire sunny side. On the other side it is yellow with white specks. The flesh is white with a yellowish tinge, fine in the grain, juicy, with a pleasantly refreshing flavour. The core is broad, with a few large seeds. The flavour is the most pronounced in March and April, and does not decrease much as the fruit ages. It is valuable as a table fruit, and for orchard culture. It has a remarkably high weight when well developed. The tree is described as a vigorous grower, compact in

habit, with erect young growths, and is an early fruiter. The fruit was figured in the *Gartenflora* in 1896 from specimens taken from the nursery of H. Lorberg, of Berlin and Biesenthal, in which year it was put into commerce. Owing to its lateness in flowering and hardiness, the variety is recommended for cultivation in cold districts, and the poor classes of soil. F. M.

The Week's Work.

FRUITS UNDER GLASS.

By ALEXANDER KIRK, Gardener to J. THOMSON PATON, Esq., Norwood, Allos, Clackmannanshire.

The vinery.—Careful attention must be given to vines that have had their bunches finally thinned, and whose berries are now swelling freely. See that both the outside and the inside borders are in a suitable condition of moisture, and this can be best ascertained by means of the border tester, which should be driven into the soil as far as the drainage material, and then be twisted two or three times so as to bring up a sample of soil. Our borders are tested in this manner near their centres at either end. If a state of dryness at the roots is permitted it will be followed by an attack of red spider on the foliage. When watering use tepid water and if a stimulant is required liquid manure: this application of water will suffice until the berries show signs of colouring. Apply a fresh mulching with manure from a spent Mushroom-bed, or moss litter to both the outside and the inside borders. If it becomes necessary to use the front ventilators during very hot weather, see that they are not opened sufficiently to admit a draught of cold air; allow the top ventilators to remain open a little way at night time. Maintain a moist atmosphere in the vinery by damping the paths and the borders twice daily, which is best done in the morning and again in the evening. Do not unduly force the vines just now, for the berries are at their stoning stage. The minimum atmospheric temperature at night time should be 65° Fahr., and 80° by day. Increase the amount of ventilation up to noon each day, at which time the maximum temperature is reached if the house has a south aspect.

Late vines, including Lady Downe's Seedling, Lady Hutt, and Black Alicante, should now have their bunches thinned for the first time. Lower the temperature to 65° at night time and 85° by day, and close the structure early in the afternoon when the thermometer registers 90°. Maintain a moist atmosphere by damping the paths freely both morning and afternoon. Continue the thinning of the bunches, removing first the small and stoneless berries. Open the ventilators in the mornings as soon as the thermometer registers 70°, and gradually increase the amount of ventilation as the day advances. Should red spider make its appearance, sponge the foliage with soft soap and hot water and apply the syringe freely.

Young vines rooted from "eyes" this spring, and that are intended for early fruiting in pots next year, should be shifted into their final pots, using a good rich compost, consisting of chopped turfy loam, some wood ashes, and sifted lime rubbish. To each barrow-load of this compost add a 6-inch potful of coarse-grade vine and plant food. Provide plenty of drainage material in the bottom of the pots, and after the soil has been well consolidated about the roots place stakes or trellises to the plants for securing them, and then apply a good soaking of tepid water. Keep the structure in which they are housed close and warm, and the young roots will soon ramify in the soil.

THE HARDY FRUIT GARDEN.

By J. MAYNE, Gardener to LORD CLINTON, Bilton, East Devon.

Apricots.—Trees that have set large crops of fruits will be benefited by an application of liquid manure water at their roots fortnightly, and this should be continued until the fruits begin to change colour. A good substitute for liquid manure is Peruvian guano sprinkled about their roots and soaked in with clear water. Although Apricots are seldom attacked by red spider and thrips, an occasional washing of the foliage with the garden engine will prove beneficial to the trees after a hot day. Young trees showing robust growths should have their leading shoots pinched to divert the flow of sap to weaker

shoots. All sub-lateral growths should be pinched at the first leaf, and each fruit should be allowed sufficient space to develop.

Figs.—These trees are usually afforded a position facing south, and although they do not require the same amount of water at their roots as stone fruits in similar places, an occasional dose of manure water during the next two months will be of benefit. Reduce the number of fruits where they are thickly placed, doing this before they have absorbed much of the plant's energy. Remove superfluous shoots weekly, and give the roots a good mulching of manure. Similar to the Apricot, the foliage of the Fig is seldom infested by insect pests unless the roots are allowed to suffer from drought. Scale insects are sometimes present, but these may be quickly dislodged with an ordinary pot label. Old trees are prone to develop much sucker-growth; any suckers should be cut away as soon as they are noticed.

General work.—Owing to the continued rains it is most difficult to keep down weeds; the only thing that can be done to combat them is to ply the hoe frequently. Shorten the more robust shoots of red and white Currants; this will allow the breadths of bushes to be netted more expeditiously a little later on. The north-west winds of June 2 and 3 respectively were rather severe, and did damage to the Apple crop, especially on standard trees. Perpetual fruiting Strawberries that are required to furnish a supply of fruits after the ordinary Strawberries are over should have all their flower spikes and runners persistently cut off till within six or seven weeks before the fruits are wanted. Recently planted Strawberries from the forcing houses should have all runners removed and the soil around their crowns stirred with the flat hoe. The varieties Royal Sovereign and Vicomtesse Hericart de Thury are both suitable kinds for autumn-fruiting after having first been forced. Plant the remainder of the pot plants immediately the fruits are cleared, as the ground is now moist and in a good condition for the roots to obtain hold.

THE KITCHEN GARDEN.

By WILLIAM H. HONESS, Gardener to C. COMBE, Esq., Cobham Park, Surrey.

Cauliflowers that were wintered in pots in a cold house, or in cold frames, and planted out as directed, on warm borders, &c., should now be about turning-in, but they may be greatly benefited if copious supplies of liquid manure, such as drainings from the stables, be afforded them. The damp and dull weather appears to have suited this vegetable, for the plants are in far better condition with us this season than they have been for several years past.

Asparagus.—In established beds that have provided the main supply, the plants should henceforward be cut less severely, and cutting should cease altogether before the end of the present month, or, at the latest, early in July, after which time the stronger shoots should be allowed to grow, the cultivator thinning out all the weakly ones to admit of plenty of light and air circulating about the plants. Cleanse the beds and alleys from all weeds, and apply a further dressing of artificial manure, eventually cutting out all seed-bearing growths before the seeds fall, for were these allowed to ripen and fall to the ground, many of them would germinate in the spring and the bed would become over-crowded with weakly seedlings, causing the crop to be very unsatisfactory. Similar attention must be afforded the younger plants in the matter of cleansing and dressing, taking great care the plants are not allowed to become over-crowded.

Potatoes.—The showery weather being so favourable to the quick growth of weeds, frequent hoeing is more necessary, even than usual, and should be continued until the Potatoes are ready for earthing-up, which should be done as soon as the plants are about 6 inches high. Continue to make periodical plantings during the next three weeks.

Endive.—A sowing should now be made for the main supply. The moss-curbed and broad-leaved Batavian are the two varieties generally found to be satisfactory. Sow the seeds in shallow drills, drawn at distances of about 6 inches apart. When the seedlings are large enough to be handled, prick them off into some rich ground, putting them at distances of 12 and

16 inches apart. Blanching is usually brought about by tying the ends of the leaves together, but should the weather in autumn be wet, the plants so treated are very liable to "damp." If the plants can be so arranged at the time of planting, that when the time comes for blanching a certain proportion can be entirely covered with some old lights, over which garden mats, or similar covering, can be thrown to exclude light, but at the same time admit a proper amount of air, very few plants will be lost in this way. Continue to make small sowings at fortnightly intervals throughout July and August.

Scarlet Runners.—The plants will now be getting hold of their sticks and making good headway. Those raised from seeds that were sown in the open will require to be thinned, and to have their sticks or poles placed in position. A later sowing should now be made for raising plants that will yield a supply later in the season.

THE FLOWER GARDEN.

By A. C. BARTLETT, Gardener to Mrs. FORD, Pencarrow, Cornwall.

Flowering shrubs.—As they pass out of flower, such hardy shrubs as *Forsythia suspensa*, *Prunus triloba*, *Staphylea pinnata*, *Philadelphus coronarius*, &c., which flower on the previous year's growths, should receive any pruning that may be necessary. In many gardens the cutting of sprays for furnishing the vases is done with care and judgment, and it suffices to keep the shrubs in a good condition without further pruning. But the same rule which requires fruit trees to be kept "open" in habit, for the sun and air to ripen the growths, and so induce them to produce flowers, applies with equal force to flowering trees and shrubs, and those which consist of a dense mass of soft, weakly shoots cannot be expected to produce an abundance of blossom. Shrubs in such condition as this should have some of the branches entirely removed, and the weaker side-shoots on the remaining branches should be pruned back to a basal bud. After they attain a height of about 10 to 12 feet, specimens of *Magnolia conspicua* and the *M. Lenné* hybrids have a naturally free and graceful habit, which does not require any treatment by the pruner's knife; but the beautiful little species *M. stellata* has a much more congested habit, and, if treated as advised above, handsomer and more floriferous specimens may be obtained. Old and exhausted bushes of *Diervilla* (*Weigela*) *rosea*, when sawn back to within a few inches of the forks of the main branches, and the roots top-dressed with farmyard manure, soon break into growth, and throw out long graceful branches, which in two years bear a profusion of fine flowers.

Flower beds.—If the plants which have a trailing habit, such as the Ivy-leaved *Pelargoniums*, are kept pegged down, they will more quickly cover their allotted space. Standard *Fuchsias* and *Heliotropes* will now only require an occasional shoot stopped to maintain the symmetry of the specimen. These plants and all quick-growing sub-tropical plants (*Eucalyptus*, *Ricinus*, &c.) must be kept securely tied to strong sticks. Keep the flowers removed from those plants which are grown only for their foliage. While there is yet room between the plants to do so, ply the small Dutch hoe frequently; this will materially lessen the work of hand-weeding.

Winter Aconites.—A few clumps dotted here and there in the front of a border give a very poor idea of the possibilities of this lovely early flower which is seen at its best when grown in large masses. It will thrive well under any large tree where the shade in spring is not too dense. The present is a good time to plant the tubers shallowly and in clumps at about 6 inches apart.

PUBLIC PARKS AND GARDENS.

By W. W. PERTIGREW, Superintendent of the Parks and Open Spaces in the City of Cardiff.

Surplus bedding plants.—In public parks the methods of dealing with surplus plants of all kinds vary in different towns. Some authorities make it a hard and fast rule to destroy all plants that are not required for the work of their immediate department, and absolutely forbid the disposal of surplus plants in any other way. From a public standpoint there is much to be said in favour of this procedure, and when once enforced it saves the officials from much unnecessary worry, trouble, and unpleasantness.

When this drastic method of dealing with this question is not followed, it is only fair that the plants should not be distributed in such a manner as to bring the parks department unduly into competition with local nurserymen and market growers. When from unforeseen circumstances a large surplus of bedding plants has to be disposed of, it is not a bad policy to sell them to nurserymen at trade prices. No one should then have any cause for complaint. Under ordinary circumstances it is generally found that after such public institutions as sanatoria, council schools, police stations, &c., which all more or less look to the parks department for some help, are supplied, there are very few surplus bedding plants left on hand.

Distribution amongst the poor.—Some public bodies in their endeavour to brighten slum property make a practice of distributing bedding plants among the poorer classes of the community. One or two corporations have even gone a step farther, and lend the people window boxes in which to grow these plants. Unfortunately this commendable action has not met with the success it deserved, for although there are always plenty of applicants for boxes and plants, many of the recipients soon tire of attending to the plants, which therefore die. Many of these borrowers also forget when the time comes to return the boxes, and they ultimately convert them into firewood!

Sale to working-class people.—A parks committee in one of the large towns in the Midlands has devised a rather novel method of dealing with surplus bedding plants—a method which, under favourable circumstances, is well worth copying. Each season more plants are propagated than are actually required for bedding purposes, and the surplus is sold at reasonable prices to working-class people. In the early part of August each year a flower show is held (under the auspices of the corporation) for two days in one of the parks, where every person who has purchased plants as above stated is entitled to exhibit them for competition. Although the public is only charged 1d. and 2d. for admission to the show, the revenue derived from this source alone is sufficient to provide excellent prizes for the successful competitors, and pay all necessary expenses.

PLANTS UNDER GLASS.

By J. G. WESTON, Gardener to H. J. KING, Esq., Eastwell Park, Kent.

Centropogon Lucyanus.—Spring-rooted cuttings of this pretty winter-flowering plant will now be ready for re-potting. See that the pots are well provided with material for drainage, and use a light, rich soil, to which has been added some sand and charcoal. Return the plants to an intermediate house after potting, and allow them to remain in this structure until they are re-established, after which they will thrive well in frames. Care should be taken that ventilation is given without causing draughts. Syringe the plants and close the frame early in the afternoon to take full advantage of the sun-heat. By the latter part of September the plants should be taken into a warm house or stove, where they will quickly advance to the flowering stage and afterwards bloom through the whole of the winter.

Decorative foliage plants.—The lightest places in a small stove should be reserved for plants that are required for table decoration in the residence, and they should receive special attention, in order to have the foliage and receptacles in the cleanest condition. Small *Codæums* (*Crotons*) and *Dracenas* that were rooted early this spring may now require a shift into larger pots, but the plants should be kept in as small pots as are consistent with their well-being, for, as a rule, these small plants are very useful for purposes of house embellishment. Among the more useful of plants for this form of house decoration may be mentioned the finer varieties of *Aralias*, including *A. elegantissima*, *A. Veitchii* and *A. V. gracillima*; small plants of *Pandanus Veitchii*; *Reidia glaucescens* (especially pleasing when in flower); *Rivina humilis*, with its long racemes of scarlet berries; small plants of *Cocos Weddelliana*; *Geonoma gracilis*, *Phoenix rupicola* and *P. Roebelenii*, *Thrinax elegans*, and Ferns in variety.

Solanum capsicastrum.—Last season's plants that were cut back this spring and plants of

this season's propagation should now be placed outside, and they may be either plunged in their pots or be turned out and planted in a border, for either system is to be recommended. Syringe the foliage each evening to ward off red-spider, for if this insect is allowed to appear, the leaves will turn yellow and eventually fall off. This *Solanum*, if planted out, should be lifted and re-potted in September, and after the necessary shading for a few days after potting, they should be exposed to full sunshine. The berries will quickly become coloured in a moderately warm house, and after they are red a slightly cooler temperature should be afforded the plants.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower to Sir TREVOR LAWRENCE, Bart., Burford, Surrey.

Epiphronitis Veitchii, a garden hybrid between *Epidendrum radicans* and *Sophranitis grandiflora*, has become so popular and plentiful that it is represented in almost every garden where Orchids are cultivated. It is very useful for decorative and exhibition purposes, the flowers having much value for use in a cut state. In some collections where many plants of this hybrid are grown, the lovely, cinnabar-red coloured flowers may be seen almost the whole year round. Being of dwarf habit the plants do not occupy a great deal of space, and they yield an abundance of bloom. At this season, after the flower spikes have been cut, young shoots appear on the old growths, and these small pieces, as soon as they begin to push forth roots, may be removed with a portion of the stem attached to them, and potted singly in pots of the smallest size that can be conveniently used. If a large specimen plant is desired, a sufficient number of these growths may be planted out in a teak-wood basket or shallow pan, using a compost consisting of sphagnum-moss and small crocks. This pretty hybrid thrives best when suspended in a light, and well-ventilated position in the Cattleya-house, and if the plants and sides of the basket are kept well damped with the fine sprayer, the usual root-waterings will not be necessary. Should the "spot" disease attack the leaves at any time, keep the plants a trifle drier and place them in another position where more ventilation is afforded.

Thunias.—As these plants pass out of bloom they should be placed in a sunny position in the cool greenhouse. Any plants that have failed to flower, and are growing to an undesirable length, should have the young points of the growths carefully pulled out, otherwise they will continue to grow for a long time. The plants will require an occasional watering at the roots so long as the leaves keep green. When the weather becomes warmer they may be stood out of doors by day in full sunshine, and each night replaced inside the greenhouse.

Miltonia vexillaria.—Plants that have passed the flowering stage will not need so much water during the next month or two, and if it is given them too liberally the old roots will certainly decay. Through the summer months plants of this *Miltonia* should be kept in as cool and well-ventilated conditions as are generally afforded *Odontoglossum crispum*.

Odontoglossum citrosum.—Plants that require fresh material about their roots should be given attention at once. They will succeed either in teak-wood baskets or in shallow pans, and should be suspended close to a roof ventilator in the Cattleya or Mexican house. These plants appreciate much fresh air at night as well as by day. Keep them well supplied with moisture throughout the growing period.

Anguloas.—The present is a good time to re-pot plants of *Anguloa Clowessii*, *A. eburnea*, *A. Ruckeri*, and *A. uniflora*. Being free-rooting subjects, they require a good depth of compost, therefore only about one-fourth drainage is necessary. The rooting material should consist of two parts of peat to one of turfy loam, the remainder consisting of chopped sphagnum-moss and small crocks. Grow the plants in the Cattleya or intermediate house, and after re-potting, and throughout the growing season, water should be afforded as advised in a former Calendar for the deciduous *Calanthes*. Carefully guard against water from any source lodging in the young growths, as this is very liable to decay from this cause.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Special Notice to Correspondents.—The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.

Illustrations.—The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but he cannot be responsible for loss or injury.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY, JUNE 15—German Gard. Soc. meet.

WEDNESDAY, JUNE 19—York Gala (8 days).

THURSDAY, JUNE 20—Linnean Soc. meet.

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich—59° 6'.

ACTUAL TEMPERATURES:—

LONDON.—Wednesday, June 12 (6 P.M.): Max. 65°; Min. 56°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—Thursday, June 13 (10 A.M.): Bar. 29.8; Temp., 64°; Weather—Bright.

PROVINCES.—Wednesday, June 12 (6 P.M.): Max. 59°; England N.E.; Min. 49°; Scotland N.

SALES FOR THE ENSUING WEEK.

WEDNESDAY—

Bedding Plants, dwarf Trees, Palms, Bays, Ferns, &c., at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 1.

FRIDAY—

Importation of *Cattleya Mendelii*, choice *Odontoglossums*, *Cypripediums*, *Cattleyas*, &c., at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.45.

Even at the present day, the manner in which soils support the life of plants and animals is mysterious in the sense that we are yet in the dark as to the nature of many of the substances contained in the soil, of the changes which they undergo, and of the part which they take in plant nutrition.

The soil is not a dead, inert mass, but is full of living organisms, which are constantly at work; it is, in fact, teeming with life. It has been well described as a laboratory or workshop, in which a number of the most wonderful chemical actions are taking place, whereby plant-food is always being prepared, little by little, for reception and assimilation by growing crops.

In this way the agencies of nature assist the cultivator of the soil in converting insoluble organic matter and mineral, rocky substances, into an assimilable form for plant-food.

It is scarcely two decades since it became known to philosophical chemists and botanists that the micro-organisms or bacteria of the soil played such an important part in aiding the growth of plants, and at the present day this new soil doctrine has already been the means of creating a distinct branch of research, termed agricultural and horticultural bacteriology. Scarcely ever before has a new discovery excited more engrossing enquiry

than this branch of science, as is abundantly proved by the extensive and constantly increasing literature and researches on the subject.

This can scarcely be a matter of surprise, when we consider the immense probabilities which may be concealed, and possibly may be realised by the correct conception of the factors that govern the vitality of the minute vegetable and animal organisms upon which, it has been conceived, so largely depends the perfect development of the higher plants, and more especially those cultivated for human food.

Hitherto, cultivators of the soil have, with few exceptions, given no thought to the invisible bacterial life that plays such an important part below the surface of the ground, through whose agency crops and individual plants are enabled to respond to the manurial ingredients added to a well-tilled soil. Yet this rational conception of the fundamental cause of soil productiveness will in future have to be taken into account by farmers, gardeners, and fruit-growers who wish to progress with the times, and who aim at deriving the greatest possible results from the capital and labour invested in their establishments.

It is not meant that every cultivator of the soil should become a bacteriologist, but he should make himself sufficiently acquainted with the nature of soil germs, and understand the conditions favourable to their life and well-being, to be able to appreciate and utilise the results achieved by the study of those who have special opportunities for searching out the intricacies of their behaviour in the soil he cultivates.

To enable us to appreciate the work which the mysterious bacteria perform in the soil, it will be necessary to consider shortly the place they occupy in the economy of nature. The three-fold functions of plant-life are—nutrition, assimilation, and reproduction. These functions are concerned with the food of plants, the digestive and storage power of plants, and the various means they adopt for multiplying and increasing their species.

Respecting the nutrition of plants, it is obvious that, like animals, they must feed and breathe, to maintain life. Plant food is of three kinds, viz., water, chemical substances, and gas. Water is an actual necessity to all plants, not only as a direct food and food solvent, but as the carrier of many essential inorganic materials into the tissues of the plant.

The chief chemical substances of which vegetable protoplasm is constituted are potash, magnesium, soda, lime and phosphates. The gases necessary to plant-growth are four—carbon dioxide (carbonic acid), hydrogen, oxygen and nitrogen. The last-named, viz., nitrogen, which constitutes more than two-thirds of the air we breathe, is, perhaps, the most important food required by plants. Yet, although this is so, the plant cannot absorb or obtain its nitrogen in the same manner in which it acquires its carbon, namely, by absorption through its leaves, nor can the plant take nitrogen into its own structure by any means as free nitrogen. Hence, although this gas is present in the atmosphere surrounding the plant, the plant will perish if nitrogen does not exist in some available form in the soil. It is in this respect that the great value

of the micro-organisms of the soil is apparent. The work is accomplished by two species of bacteria, the first, which converts ammonia gas to nitrites, and the second which converts the nitrites into nitrates, in which form it is taken up and used by plants as food.

OUR SUPPLEMENTARY ILLUSTRATION represents a view in the Rhododendron dell at Kew in early summer. Of all the many distinct and ornamental features of these famed gardens, this dell is one of the most attractive, especially at this season of the year, for, although it is possible to find some plant of Rhododendron in flower out of doors at almost any time between Christmas and the middle of July, late May and early June is the time when the most brilliant effects are produced by these plants. Plants of hardy Rhododendrons are to be found at Kew in several other parts of the gardens, but the general collection of the larger-growing, evergreen species and varieties is to be found in the spot depicted in our illustration. The dwarf evergreen species and varieties, and a few of the rarer deciduous kinds are planted near to King William's Temple, whilst the deciduous or Azalea section is grouped together in a number of large beds on the north side of the Syon House Vista. On either side of the path known as the Broad Walk, and which leads from the main entrance on Kew Green to the Palm House, are planted, in large beds at intervals, a number of the best garden varieties of Rhododendrons. By this means it is possible to see at a glance what effect a particular sort produces when planted in a large mass. In these beds are accommodated such handsome varieties as Lord Palmerston, Madam Carvalho, Michael Waterer, Lady Grey Edgerton, James Nasmyth, John Waterer, Mrs. A. Waterer, Mrs. W. Agnew, Doncaster, and Minnie. In addition to these beds there are others containing groups of species and special varieties, including *R. yunnanense*, *R. rubiginosum*, *R. racemosum*, *R. indicum amœnum*, *R. ledifolium*, &c. Near to King William's Temple are found *R. punctatum*, a free-flowering, evergreen species, a native of the United States; the exceedingly beautiful *R. yunnanense*, which bears numerous white flowers that are heavily blotched with reddish-brown; the lovely little *R. racemosum* from Western China; the tiny-leaved *R. parvifolium*, and *R. serpyllifolium*, with still smaller foliage. An interesting deciduous species is *R. rhodora*, from N. America. The collection also includes the two Japanese rosy-purple-flowered species, *R. rhombicum* and *R. dilatatum*; the curiously flat-flowered *R. lepidotum*; *R. Smithii aureum* and *R. Broughtonii aureum*, both hybrids between evergreen and deciduous species; *R. Przewalskii*, *R. myrtifolium*, *R. hirsutum*, *R. glaucum*, *R. arbutifolium*, *R. dauricum*, *R. campylocarpum*, *R. Metternichii*, *R. Smirnowii*, *R. rubiginosum*, *R. indicum* varieties, and many another. As stated above, the Rhododendron dell contains a very fine collection of the hardier, strong-growing species, together with a selection of the more ornamental garden varieties, both old and new. Some are small plants, but the majority are of large dimensions, some specimens being from 12 to 15 feet in height and as much across. Among the larger specimens are examples of *R. macranthum*, *R. purpureum splendens*, *R. fastuosum fl. pl.*, the varieties Lord Wolseley, Lord Palmerston, Blanch Superb, Madam Carvalho, Lady Eleanor Cathcart, Kewense, Fortunei, Broughtonii, Manglesii, catawbiense, and Luscombei. There are also a number of hybrids of the fragrant-flowered *R.*

Supplement to the "Gardeners' Chronicle."

THE RHODODENDRON DELL AT KEW.

Temple Press Ltd., Printers, 7-15, Rosebery Avenue, London, E.C.

Fortunei. The Azaleas or deciduous Rhododendrons are represented by many hundreds of plants, beautifully situated between stumps of old trees in an open glade. In this quarter of the garden is to be seen just now some of the most exquisite shades of colouring imaginable, including yellow (pale and bright), orange, reds of many shades, delicate pink, white, rose, and all intermediate shades. These Azaleas represent both species and hybrids, the former including *R. calendulaceum*, *R. nudiflorum*, *R. sinense*, *R. occidentale*, and *R. flavum*. For

Anchusa and some of the other members of the *Boraginaceæ* is only equalled in depth and beauty by that of the *Gentians*, and in "Opal" is seen the beautiful shade of blue suggested by the name.

LINNEAN SOCIETY.—The next meeting will be held on Thursday, June 20, at 8 p.m., when the following papers will be read: 1, by the late Dr. MAXWELL T. MASTERS, F.R.S., "Distribution of Conifers of China"; 2, Mr. CLEMENT REID, F.R.S., and Mrs. REID, "Pre-glacial Flora of

Canadian Horticulturist for the month of May, the prospects are favourable for all kinds of fruits. The trees have come through the winter uninjured except in Kent county, where the Peach buds are badly cut and many young trees killed; as also four-years-old Pear trees. Fruit buds on Apple trees are plentiful everywhere, and the trees are healthy.

ROYAL METEOROLOGICAL SOCIETY.—A meeting will be held in the rooms of the Society, 70, Victoria Street, Westminster, S.W., on Wednes-

FIG. 162.—SPRAY OF *CHOISYA TERNATA*: FLOWERS WHITE AND FRAGRANT (see page 382).

delicacy of colouring and for richness of perfume deciduous Rhododendrons are unrivalled amongst plants, and no garden should be considered complete without a selection of them.

FLOWERS IN SEASON.—From Messrs. B. LADHAMS, Ltd., Shirley Nurseries, Southampton, we have received flowering sprays of *Anchusa italica* "Opal." The blue of the flowers of

Great Britain"; 3, Dr. J. STANLEY GARDINER "Cruise of H.M.S. 'Sealark' " Part II.; 4, Mr. A. W. WATERS, "On Tubucellaria"; 5, Dr. N. WOLFENDEN, "Cruise of the 'Silver Belle'"; 6, Mr. E. A. N. ARBER, "Triassic Species of Zamites and Pterophyllum."

FRUIT PROSPECTS IN CANADA.—According to advices received from correspondents of the

day, June 19, at 4.30 p.m., when the following papers will be read: "Weather and Crops, 1891-1906," by FRANCIS CAMPBELL BAYARD, LL.M.; "The Relation of the Rainfall to the Depth of Water in a Well at Cirencester, 1908-1906," by CHARLES P. HOOKER, L.R.C.P. Mr. WALTER CHILD will exhibit the "Step" Anemometer, an instrument which he has designed to obviate the "sheltering" error.

NATIONAL ROSE SOCIETY'S EXHIBITIONS IN 1907.—The Metropolitan Exhibition will be held in the Royal Botanic Gardens, London, on Thursday, July 4; the Provincial Exhibition at Saltaire, in Yorkshire, on Tuesday, July 16; and the Autumn Rose Show, in the Royal Horticultural Hall, Vincent Square, Westminster, on Tuesday, September 24.

POTATO "MIDLOTHIAN EARLY."—The *Scotsman* last week stated that: "Market gardeners along the coast report very rapid growth in Potatoes during the past week, especially in plants of Midlothian Early, which in many gardens are just meeting in the drill." This variety secured both first and second prizes at the recent show of the Royal Caledonian Horticultural Society in Edinburgh.

THE FRENCH TOURING CLUB.—This body has divided the sum of 5,000 francs among several forestry societies for the purpose of improving the woods and meadows. The club seeks to influence the schoolmasters and the children in this scheme of beautifying the landscape by offering prizes. Arbour Days, which in previous years have had good results in the same direction, will likewise be instituted, seeing that these serve the aims of the club in an excellent manner.

THE TERMINAL BUDS OF RUBUS.—An example of the manner in which plants may suffer injury from hard frosts is given by a correspondent in the *Gartenflora* for May 1, 1907, p. 238. He observes that when nature's warning is disregarded the plant may suffer, stating as an example some one-year-old shoots of the large-fruited Blackberry, some of which had been taken down from a fence and laid on the surface of the soil, but others had been left on the fence. The points or end buds of the long growths of the Blackberry consist in late autumn of a globular thickening—a winter bud capable of developing roots. This point is intended to form a new plant by sinking into the soil and taking root. The union with the earth affords protection to these terminal buds, for all shoots that were in a position to do this escaped injury from frost; whilst those of the same age that were fastened to the fence were more or less damaged.

THE VEGETABLE PRODUCTIONS OF BULGARIA.—The visitor to the exhibition now open at Earl's Court who has observed the large collections of pulses, grains, and other seeds of plants, as well as the fine specimens of timber in the rough state, and also worked up into articles of domestic use; the wines, tobacco, and hemp, and the attar of Roses made at Kasanlik, may have been astonished at their intrinsic good quality and great abundance. Whilst the so-called Balkan States were under Turkish rule, every kind of art and culture remained in a backward condition, but under the more enlightened rule of the present Sovereigns there are many signs of improvement and progress on every hand, and internal trade and exports have largely increased. It is interesting to learn from *Thalacker's Offerte Journal*, of recent date, the amount and value of the imports and exports in plants, shrubs, flowers, flowering bulbs, and garden and forest tree seeds. The imports in these articles in 1905 amounted to 41,562 kg. (52,516 frs.), of which Germany contributed 15,946 kg. (18,766 frs.) The imports of fresh fruits amounted to 1,357,985 kg. in value, 237,161 frs., of which quantity only 19 kg. of the value of 7 frs. came from Germany. Bulgaria's exports came to about 1,817,814 kg. (61,528 frs.), of which total 24 kg. (7 frs.) only came to Germany. The above statistics show that Bulgaria is a country in which horticulturists may find a market and do good business if ordinary prudence is exercised.

THE ONION SEED CROP IN CALIFORNIA.—The latest estimate of damage to the prospective Onion seed crop in California places the number of acres totally destroyed at something over 1,000, and a crop of from 80 to 50 per cent. on the remaining area. One grower states that, in his opinion, Onion seed will be worth from 2 dollars to 8 dollars per pound next autumn. In Germany Onion seed was among the short items this season, except Giant Zittau, which was in abundance, owing to the unusually large plantations made in 1906; and the price of this variety went down lower than ever.

ELECTRICITY AND THE VINE.—Mr. GEORGE MASSEE, writing in *Knowledge and Scientific News* respecting the use of electricity in promoting the growth of the Vine and in destroying its parasitic enemies, states that the "discovery was first made by a cultivator of Vines. The method consisted in the arrangement of two series of metallic conductors traversing the roots at a depth of about 60 centimetres, so as not to injure the above-ground portion of the Vines. Each series of conductors forms with the plants it traverses an electrode, and electric currents are liberated by neighbouring electrodes of contrary signs. One of the collectors is bound to a lightning rod, about 20 metres in height, furnished at its extremity with a quantity of small copper points. The other is attached to a metal plate buried in the ground. The experiment was tried on Vines badly infested with Phylloxera, and at the end of the first season it was found that most of the insects were killed, and at the end of the second season not a single living insect could be discovered. In addition to destroying the Phylloxera, it was observed that the treated Vines grew more vigorously than a check batch of untreated ones, the quantity and quality of the fruit was also much better in the treated batch. This primitive method of applying electricity has been modified by Professor BARDE, who finds that in place of a current of about 120 volts as first used, currents varying between 1,000 and 2,000, or even 3,000 volts can be applied without producing the slightest injury to the plants treated."

LEGACIES FOR SERVANTS.—The Hon. MARK ROLLE, who died in April last, left his butler and housekeeper £60 each, his gardener, forester and keeper, £50 each, all of Stevenstone, North Devon; while at Bicton, his East Devon Estate, the gardener, forester, clerk of works, and keeper, all benefit by £50 each.

THE CHEROKEE ROSE (R. LÆVIGATA).—A correspondent in *Horticulture*, U.S.A., writing in regard to the statement that is made in *Cyclopedia of American Horticulture* that the Cherokee Rose "can be grown satisfactorily away from its native regions only in a greenhouse," states that if the author of that sentence is still alive, and will cross the Continent, he may see a hedge of this Rose 50 feet high, as many feet in width, and eight times as long, growing in the private grounds of Mr. TEVIS, at Bakersfield. When in bloom it is one of the most beautiful sights in California.

PICEA MORINDOIDES, REHDER.—We have received a cone-bearing shoot of this interesting Spruce from Sir EDMUND G. LODER, Bart. The tree from which it was taken is growing in his garden at Leonardslee, Horsham. This is the first recorded instance of this Spruce bearing cones in Great Britain. We only know of one other tree of goodly size, and that is in Lord ANNESLEY's garden at Castlewellan. *Picea morindoides* (see *Gardeners' Chronicle*, April 7, 1906, Fig. 84) is of Himalayan origin, and is one of the "Flat-leaved Spruces." In habit it resembles *P. morinda*, but in leaf-character is scarcely distinguishable from *P. sitchensis*. Its status as a species was first recognised by Mr. REHDER, who found the tree in the garden of M. ALLARD, near Angers.

This tree produces cones every year, but M. ALLARD says it has never borne fertile seed. We hope Sir EDMUND LODER may have better fortune. It is not unlikely, as was pointed out by Dr. HENRY in these columns, March 8, 1906, that other specimens are in existence in Britain. An illustration of the Castlewellan tree was given in our issue for May 5, 1906, p. 294. The cones are 1½ to 2 inches long, cylindrical, and in colour reddish purple.

AGRICULTURAL EDUCATION.—The Departmental Committee, of which Lord REAY is chairman, held meetings on the 4th, 5th, and 6th inst. Professor LLOYD MORGAN, University College, Bristol; Dr. H. R. MILL, Royal Meteorological Society; Mr. S. KIDNER, Milverton, Somerset; Mr. E. V. V. WHEELER, Worcester County Council; Mr. EDWARD BROWN, lecturer in poultry keeping, &c.; and representatives of the Harper Adams Agricultural College, Newport, Salop, of the University College of North Wales, Bangor, and of Bigod's Hall, Dunmow, Essex, attended and gave evidence.

WANSTEAD PARK.—Last winter the West Ham Distress Committee, with the consent of the Epping Forest Committee, undertook the task of excavating and concreting the bed of the Heronry Pond in Wanstead Park, and enlarging the islands; the Distress Committee were thus able to find work for a large number of unemployed men for many weeks during the winter. The amount originally voted has been found insufficient to complete the undertaking, and the Epping Forest Committee has therefore agreed to provide £500 out of the capital account of the Epping Forest Fund, subject to certain conditions, to finish the work.

IRISH INTERNATIONAL EXHIBITION.—We are informed that an exhibition of Sweet Peas will probably be held within the precincts of the Irish International Exhibition, Dublin, towards the end of July. Due notice will be given of the arrangements as soon as completed.

THE LAW OF TRESPASS.—At a general meeting of the Leek and District Agricultural Society, held on May 15, it was decided to send to the President of the Board of Agriculture and the President of the Royal Agricultural Society, the following resolution:—"That owing to the unsatisfactory state of the law relating to trespass, and the great amount of damage frequently caused thereby to farmers, Parliament be petitioned to amend the law with respect to the penalties, &c., or possibly, a clause might be inserted in the English Land Bill which the present Government have introduced."

GLADIOLUS "PEACE."—Referring to the description of this variety on p. 205, Mr. H. H. Goff, Simcoe, Ontario, Canada, writes us as follows:—"The variety is not pure white, but has a delicate lilac feathering on the inferior petals. It is, however, a grand flower of rare quality, and the plants are extremely vigorous. It was named before Messrs. Kelway's flower of the same name came under my notice."

Publications Received.—*Flower Decoration in the House.* By Miss Gertrude Jekyll. Country Life Library, George Newnes, Ltd., Covent Garden, W.C. —*The Art and Craft of Garden Making.* By Thomas Mawson; 3rd Edition. B. T. Batsford, 94, High Holborn, London.—*From Collins' Clear Type Press.* London, and Glasgow, *The Great Refusal, The Secret Woman, The Brown Eyes of Mary, and The Golden Butterfly.* These are the first four books in the issue of Collins' "Handy" Modern Fiction, published at 7d. each net. These little books are neither so ephemeral as the 6d. novels in paper covers, nor expensive like the 6s. volumes. Each book is clearly printed in bold type, with coloured frontispiece and title page specially drawn for the series.

A DISEASE OF AGAVES.—These plants have, under cultivation, hitherto escaped the attack of fungoid disease, but now Dr. COOKE writes that a species of anthracnose, which developed on young Agaves in Italy, has made its appearance in the United States, and may ultimately reach these islands. All the species of *glœosporium* and *colletotrichum* are most persistent pests of plants under cultivation. He says: "In the present instance a number of small Agave plants were placed in one of the greenhouses of the Missouri Botanical Gardens, and in a short time many of them were found to be dying from a disease which at first attacked the older leaves. The conidia of the fungus apparently germinate on the surface of the host plant, and gain entrance through the stomata or through wounds. The tissue of the leaf is penetrated by the mycelium in all directions, and forms either a circular or an elliptical spot, which is at first darker in colour than the surrounding tissue, but changes finally to either a brown or a grey colour. The adjacent tissues under moist conditions turn brown and rot rapidly, the mycelium penetrating to all parts of the leaf. Under less humid conditions the affected tissues of the host slowly darken in colour, often assuming a purple tinge. The pustules are usually formed in concentric rings, and differ from those in species of *glœosporium* in being furnished with setæ, which is a characteristic of *colletotrichum*. The following is a more explicit description of the fungus causing the disease. 'Spots circular or elliptical, often becoming confluent, olive, changing to grey or brown; pustules spherical to oblong, usually breaking through the epidermis in concentric rings, and ejecting orange-coloured masses of conidia; setæ acute to blunt, light brown, 2 to 5 septate, 150 to 170 × 5 to 6 mm. Conidia oblong or cylindrical, hyaline, with one or two guttules 16 to 31 × 5 to 6 mm. Conidiophores erect, hyaline, usually simple, but variable in length. No ascigerous stage has been found.' This pest has been recognised upon leaves of six or seven species of Agave under cultivation, and often causes the death of young plants. The species thus characterised is named *Colletotrichum Agaves* (Cav.), and was first detected on leaves of Agave *Utahensis*, and has presumably developed on the leaves of a species from Mexico. The superintendent of the garden has been successful in checking the spread of the disease, which is favoured by moist conditions. All the diseased plants are placed in a separate locality, and the lower leaves are removed as soon as they show signs of the disease. Bordeaux Mixture, made according to the ordinary formulæ, is beneficial in preventing the spread of the fungus to adjacent plants."

REMEDY FOR SLUGS.—A correspondent in a morning paper writes: "A capital means of combating slugs is malt-dust, which can be obtained from any brewery. It should be sprinkled around the seedling plant in an unbroken circle. As soon as the slug gets into this dust its attention is centred on ridding itself of the clinging material."

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

A YELLOW RHODODENDRON.—I read with much interest the article on hardy *Rhododendron* hybrids in the issue for June 1, but I cannot agree with the writer when he says that "up to the present no hardy, yellow-flowered *Rhododendron* has been raised." We have had in the garden here for many years a pure yellow variety precisely similar to *R. Thompsoni* except in colour. It is about 8 feet in height and the same through, and it is quite hardy. We have also *R. Smithii aureum*, sent to Lord Annesley from Kew, which is a good yellow colour and has been some years out-of-doors; this also appears to be perfectly hardy here. J. Ryan, *The Gardens, Castlewellan, co. Down, Ireland.*

THE CULTIVATION OF WATSONIA ARDERNEI.—The account (on p. 273) of failure to grow *Watsonias*, by F. W. G., may just as well have been written of many thousands of bulbs or corms that find their way to English gardens, and in practically every instance the trouble arises during the resting period and immediately before it. It is here, certainly, that cultivation is faulty, and more generous treatment is necessary for the plants whilst in growth and at rest also. In the first instance F. W. G.'s pots were too small. A *Watsonia* could not perfect a flower spike and form a new bulb of flowering strength in such confinement, and particularly would failure be likely to ensue if every endeavour was not made to maintain the leaves in a green state as long as possible. Their root system is exceedingly strong and the roots are often as much as one yard in length. A good way of treating *Watsonias* is to grow three bulbs in a 12-inch pot, using a compost of fibrous loam mixed with one-fourth its bulk of dried cow-manure, and taking care to provide the pots with good drainage. The bulbs may touch the sides of the pots with advantage to their roots. Forcing will destroy their vigour; they should be allowed to grow slowly in the temperature of a cool vinery, giving cow-manure water when the pots have become filled with roots. Here they may remain till the spikes develop, when exposure to more sunshine will prepare them for the conservatory or display-house. Cultivation does not end here, however, for as long as a green leaf remains to do the work of building up new corms, water will be required, and if plenty of leafage in an active state survives the inflorescence, manure water may be freely given. All the ripening the bulbs will need is readily provided by half plunging the pots in the open sunshine; here they will rest quietly till winter, such rainfall as they may get sufficing to maintain their freshness and vigour. They will start into growth at their accustomed time, but often remain quiescent for many weeks with the growths just appearing through the soil, and one can extend the flowering season by selecting such as are precocious, introducing these to more heat, allowing the others to follow. A *Watsonia* that flowers exceptionally well generally makes two or three corms, and these need every chance of development after the flowers have passed. If such development is continued at the expense of a dry resting period it does not matter. One can flower a fully developed corm without previously resting it for a long time, but one cannot flower an undeveloped corm under any conditions. The more one studies Cape bulbs, or those from other warm climates, the more is one inclined to regard the prolonged resting period as of secondary importance. The plants cannot do the work in a handful of soil they have been accustomed to do in a bushel; pot culture is still an artificial way of growing plants, and successful only so long as it is aided by good culture. One can follow guardedly in the footsteps of the man who grows *Chrysanthemums* and vegetables well; build up flowering bulbs by extending the growing season to the uttermost limits; rest can follow this if the bulbs have gained strength enough to flower. Any reference to *Watsonias* would be incomplete without a warning. These plants are wholly incapable of withstanding fumigation without injury, a character shared by many Iridaceous plants from the Cape. G. B. Mallett.

CRUSHED SHELLS AS A FERTILISER.—The value of shells in a crushed state is not generally recognised when the compost for various plants is being prepared, or top-dressings for Vines and other fruit-tree borders. It is the custom to mulch such freely each year with farmyard manure, and it may be sometimes carried to excess causing the borders to become soddened and soured. A beneficial change may be made occasionally by the use of crushed shells, even if a slight mulch of some kind has to be given later for conserving moisture in the soil. It is with pot plants, however, that I have noticed the most satisfactory results from the free addition of crushed shells in the compost, and also as part drainage. The roots of fruiting Pines revel in it, proving it to be a good "root producer" as well as fertiliser. In turning out the old stools of these as well as those of *Chrysanthemums* that had been grown for producing exhibition blooms, I have found a solid mass of roots where an inch of crushed shells has been placed over the corks. I would not advise the use of oyster shells in a whole state for drainage, as they decompose only very slowly and the soil is apt to collect in the inside of the shells and prevent

the water getting away freely even when the concave side is placed downwards. Such shells should be well broken and then passed through a sieve with a half-inch mesh, using the rougher for placing over the corks and the finer for mixing with the soil. We prefer this to sand, as porosity is the better secured and the staple improved. The shells need not be those of oysters, as I have used, with equally good results, shell gravel which forms suitable paths in ferneries. Richard Parker.

HARDINESS OF THE CAMELLIA.—Referring to *Practical Gardener's* note, p. 846, I do not think the *Camellia* can be considered hardy in this county, for on three occasions stout, carefully-hardened bushes have been planted at Grimston, but in the course of two or three years they have all died. They were afforded sheltered positions and had their stems and main branches wrapped with the common bracken for protection in the autumn. In one case the trees survived through two mild winters practically unharmed, but the third season, when upwards of 15° of frost were registered they succumbed. The plants included half a dozen varieties, *Marchioness of Exeter* being the hardiest. It may be stated that Grimston is situated in mid-Yorkshire, at the end of lower Wharfedale, and at an altitude of about 60 feet above the sea-level. The sub-soil consists of magnesian limestone. H. J. C., *Grimston Gardens.*

STRAWBERRY "KENTISH FAVOURITE."—I wish to direct the attention of gardeners and market growers who have not yet grown this variety to its valuable qualities as an early forcing kind. I forced a few plants this year in the same house, and concurrently with a batch of *Royal Sovereign*. The fruits set well, swelled evenly and rapidly, and ripened eight days before those of *Royal Sovereign*. Each plant perfected from eight or ten fruits, which averaged from 2½ to 3 ounces each. They were solid and firm in texture, somewhat sweeter and deeper in colour than *Royal Sovereign*, and possessed a distinct "pine" flavour. The firm texture of the fruit should ensure their travelling well in transit. The habit of the plant is dwarf, sturdy, and compact. I should not like to prophesy that it will supersede *Royal Sovereign* as an early forcing variety, but I predict that it will speedily attain a prominent position, as a variety for early forcing. T. Challis, *Wilton House.*

YORKSHIRE GALA.—This annual horticultural exhibition will be held on June 19, 20, and 21. The Yorkshire Gala is the only northern prototype of the Temple Show in the south. Next year (1908) is its jubilee, and already the enterprising committee has issued a preliminary schedule of extra prizes to be awarded on that occasion. These prizes are certainly of an original character, and may reasonably be expected to produce good competitions. I should like to suggest that medals of varying value be given for the best plans of how to lay out gardens varying in size from half an acre upwards, and for the best exhibit of implements useful in horticulture generally. The cost of doing this would not be great, and it would have some educational value. *Yorkshire Gardener.*

MICE ATTACKING LILIES.—The best course for B. L. to take in regard to field mice destroying his Lilies is to dust the flower heads and young leaves with red lead. He will find that the mice will not eat many buds, as they dislike the taste, and it will poison them if they venture to do so. I have known mice to eat Lilies before, and have found poisoning the only remedy. E. H. Hallett.

SCHIZANTHUS AT COTE HOUSE.—Of late years the greenhouse *Schizanthus* has become exceedingly popular as a pot plant, and great improvement has taken place in the quality and colour of its flowers; especially is this seen in the type known as *S. Wisetonensis*. Amongst the improvers of this flower must be included Mr. W. H. Bannister, of Cote House Gardens, Westbury-on-Trym, Bristol. Mr. Bannister's strain is a very fine one, the plants being of medium size and neither very dwarf nor of the great height to which plants of the older stocks will rise, but averaging about 4 feet. Many of the lateral sprays of his flowers are fully 18 inches in length, the habit of the plants being much branched, and the colours very varied. The flowers are in demand at Cote House for cutting, and successional batches are raised

FIG. 163.—PRIMULA X UNIQUE, A HYBRID FROM P. COCKBURNIANA AND P. PULVERULENTA WITH DETAILS.

to furnish a supply throughout the year. In a large roomy greenhouse in these gardens these plants make a beautiful display. The colours of their flowers have been specially selected; among them are some very distinct shades, and from a stock of plants yet unflowered more "breaks" are anticipated. Any plant that falls below the required standard is at once removed, so that no opportunity is afforded for retrograde influence in the stock. An observable point in Mr. Bannister's plants is their extreme floriferousness, with an accompaniment of neat foliage, the habit generally being devoid of coarseness that is common to many stocks. This is due to cultivation, for instead of using a rich compound, or even new turfy loam, Mr. Bannister employs soil that has been turned out of *Chrysanthemum* pots in spring, and to this is added leaf-mould. This is found to provide ample leaf growth without coarseness, and a plentiful supply of blossoms. The plants are grown in pots of various sizes, but the main batches are accommodated in 5-inch and 6-inch receptacles. A few selected plants required for special purposes are given still larger-sized pots. W. S.

SEQUIA (TAXODIUM) SEMPERVIRENS.—Is there any gardener now surviving who can tell me by whom and in what year this tree was introduced to cultivation? Kent, in Veitch's *Manual of Conifera*, and others who have copied him, assign it to Hartweg, in the year 1846. Now, I have searched Hartweg's journals, and the volumes of the *Journal of the Royal Horticultural Society* for several years, and can find no mention of his having sent seeds to the Horticultural Society, for whom he was working. Neither is the tree mentioned as among the introductions of the society by Gordon. The first mention I can find of this tree in the *Gardeners' Chronicle* is on March 17, 1849, when James Duncan, writing from Basing Park, says that in the latter part of July, 1847, a plant 9 inches high was transferred from a pot and planted out. In the same vol., p. 280, the Editor, in notices to correspondents, says: "In general it may be considered hardy, but it is sometimes injured in severe winters." This looks as though it had been some years in cultivation at that time. But Hartweg's first journal from California only arrived in London on November 4, 1846, in which he speaks of having seen *Taxodium sempervirens* near Santa Cruz, where he did not arrive till June 22, 1846. Even if seed was collected then, which seems extremely doubtful, it could hardly have produced a plant 9 inches high by the following July. H.

PRIMULA X UNIQUE.

WHEN *Primula Cockburniana* was first exhibited by Messrs. James Veitch & Sons, Ltd., at the meeting of the Royal Horticultural Society on May 23, 1905, it was at once recognised as a very valuable addition to the genus, for although the plant itself did not possess the habit and characteristics of a good garden species, the orange-scarlet colour of its flowers was distinct from anything of the kind previously seen in *Primulas*. Therefore it was said, when the plant was illustrated in these columns, that if used as a parent it might produce a new race having orange-scarlet flowers and a good garden habit. The beginning has been made, and in *Primula x Unique* (fig. 163) a hybrid is illustrated in which *P. Cockburniana* has been blended with the strong-growing and free-flowering *P. pulverulenta*. Several plants from this cross were exhibited recently by Messrs. Veitch at the Temple Show, and from these Mr. Worthington G. Smith has prepared the illustration. One plant bore six stout inflorescences, with flowers in verticillate whorls, the calyces and pedicels being covered with a white mealy wax, or farina. The foliage of the hybrid greatly resembles that of the common Primrose, the lamina being decurrent along the petiole, as in *P. pulverulenta*, but in *P. Cockburniana* the lamina is developed very little on the petiole. The colour of the petals is described by our artist as "Turkey red"; it appears

to be a mixture of the colours seen in the parents. By further crossings and sports, aided by careful selection, we have no doubt but the clear-orange colour of *P. Cockburniana* will be restored, and it will be allied with the vigour of *P. pulverulenta*. *P. pulverulenta* is a perennial, and *P. Cockburniana* is not; it will therefore be interesting to see if *P. x Unique* has a perennial character. It will be seen from the illustration that the pollen-grains of *P. pulverulenta* and *P. Cockburniana* are alike, but those of the hybrid are of two sizes.

SOCIETIES.

ROYAL HORTICULTURAL.

JUNE 11.—The Hall in Vincent Square, Westminster, was filled with exhibits on the occasion of the ordinary fortnightly meeting on Tuesday last.

Cuthbertson, Geo. Gordon, W. Bain, Jno. Green, M. J. James, A. Turner, Geo. Paul, C. T. Drury, Jas. Douglas, C. E. Pearson, J. T. Bennett-Poe, Walter T. Ware, W. Howe, Jas. Walker, J. F. McLeod, C. R. Fielder, H. J. Cutbush, H. J. Jones, Ed. Mawley, R. Hooper Pearson, R. C. Reginald Neville, and J. Jennings.

Messrs. H. B. MAY & SONS, Edmonton, displayed 46 varieties and species of *Nephrolepis*. This rich collection was of much merit, many of the plants being exceedingly large, and all were well developed. The most showy were varieties of *Nephrolepis exaltata*, *N. e. Pieroni*, and its handsome derivatives, *N. e. Todæoides*, *N. e. canaliculata* (some of the leaves had tassell-like growths), *N. e. Whitmani*, &c. We noticed a magnificent plant of *N. elegantissima*, and another of *N. exaltata superba*. There were also seen the rare *N. acuta*, with very dark foliage, and the climbing species, *N. oblitterata*. (Silver-Gilt Flora Medal.)

Mr. L. R. RUSSELL, Richmond Nurseries, Richmond, Surrey, displayed handsome foliage

species introduced by their collector, Mr. E. H. Wilson. *Aconitum Hemsleyanum* is a climbing species; *Vitis flexuosa Wilsoni* is another climbing plant, and an addition to the numerous ornamental vines already in cultivation; *Lonicera Maackii* was figured in our issue for April 27 last. *Enkianthus campanulatus*, *Magnolia parviflora*, *Olearia ilicifolia*, and *Vitis Henryana* are other interesting plants noticed in this exhibit. As a separate group Messrs. VEITCH exhibited 110 plants of *Gloxinias*, and a desirable strain of long-spurred *Aquilegias*. (Silver-Gilt Banksian Medal.)

Messrs. HUGH LOW & CO., Bush Hill Park, Enfield, showed a remarkable collection of Carnations, principally vases of American or winter-flowering kinds, but many were pot plants, including some fine specimens of *Souvenir de la Malmaison* varieties, amongst which were *Duchess of Westminster*, *H. J. Jones*, *Baldwin*, *Lady Rose*, and *Princess of Wales*. Large plants of this latter variety were presented, one of which was carrying 56 blooms. Messrs. HUGH LOW & CO. also exhibited plants of

FIG. 164.—PRIMULA PULVERULENTA (ONE OF THE PARENTS OF *P. x UNIQUE*) AS IT FLOWERED IN MESSRS. JAMES VEITCH AND SONS' NURSERY AT COOMBE WOOD.

The following awards were made by the ORCHID COMMITTEE to novelties submitted for certificate, namely, one First-class Certificate and one Award of Merit.

The FLORAL COMMITTEE recommended an Award of Merit to a blue-flowered species of *Meconopsis* (*M. racemosa*), and similar awards to six other plants.

No award to a novelty was made by the FRUIT AND VEGETABLE COMMITTEE on this occasion.

In the afternoon 135 new Fellows and four Associates were admitted to the privileges of the Society, and Mr. Walter P. Wright delivered a lecture on "Arches, Pillars, and Pergolas."

Floral Committee.

Present: W. Marshall, Esq., and Messrs. H. B. May, T. W. Turner, G. Reuthe, Chas. Dixon, J. W. Barr, W. P. Thomson, E. H. Jenkins, W.

plants of stove and greenhouse species. Well-grown and highly-coloured *Dracænas*, *Pandanus Veitchii*, *Bertolonias* in variety, *Codiaeums* (*Crotons*), *Maranta hieroglyphica*, *Heliconia illustris rubicaulis*, *Ficus radicans variegata*, *Aralias*, *Alpinias*, *Phyllanthus*, and other equally beautiful subjects made a pleasing display, the inclusion of *Nertera depressa*, in fruit, along the front of the display giving a pleasing finish to the exhibit.

Messrs. WM. BULL & SONS, King's Road, Chelsea also displayed ornamental-leaved plants of exotic species. The back row was formed of *Aralia Veitchii*, and in the main group were *Bertolonias*, *Aglaonema pictum*, *Dioscorea chrysophylla*, *Hoffmannia Ghiesbreghtii*, *Cryptanthus Beuckeri*, *Dorstenia argentea*, *Eugenia myriophylla*, &c.

Messrs. JAMES VEITCH & SONS, LTD., King's Road, Chelsea, S.W., again showed an assortment of new plants principally of Chinese

Metrosideros floribunda. (Silver-Gilt Banksian Medal.)

Mr. C. F. WATERS, Deanland Nursery, Balcombe, Sussex, also showed remarkably well-grown Carnations in the best varieties, including *Nelson Fisher*, *Floriana*, *Pride of Exmouth*, *Lady Bountiful*, *Enchantress*, *Lady Carlisle* (rose), *J. Street* (scarlet), &c. (Silver-Gilt Banksian Medal.)

Messrs. G. BOYES & CO., Aylestone Nurseries, Leicester, displayed vases of Carnations of the winter-flowering type.

Mr. GEORGE MOUNT, Canterbury, contributed a magnificent display of Roses that occupied the whole side of one of the long tables. Arches of rambling varieties formed a pleasing background, and at intervals large banks of such handsome varieties as *Captain Hayward*, *Ulrich Brunner*, *Mrs. J. Laing*, *Mrs. Sharman Crawford*, and *Frau Karl Druschki*, with small *epergnes* and vases filled with specimen bloc

of exquisite kinds, and with here and there a pillar plant of Hiawatha, Dorothy Perkins, or Blush Rambler formed one of the prettiest and most meritorious displays in the Hall. (Silver-Gilt Flora Medal.)

Messrs. B. R. CANT & SONS, Colchester, exhibited varieties of garden Roses, especially noteworthy being single Briar varieties such as Austrian Briar (copper and yellow forms), Bardou Job, &c. (Silver Flora Medal.)

Messrs. FRANK CANT & Co., Colchester, also showed garden varieties of Roses, and some excellent plants of the popular Dorothy Perkins variety. (Silver Banksian Medal.)

Messrs. PAUL & SON, Old Nurseries, Cheshunt, displayed Roses of climbing varieties all very freely flowered. Especially beautiful were the white Trier and the large single white Rosa sinica. Some grand blooms of the variety Dean Hole were noticed, and in the group were specimens of the long tubular-shaped flowers of *Lonicera Hildebrandtii*. (Silver Flora Medal.)

Mr. GEO. PRINCE, Longworth, Berks, showed bunches of Roses from the open, and some choice specimen blooms of such notable kinds as Mrs. Ed. Mawley (excellent examples), Medea, E. V. Hermanos, Maman Cochet, Rainbow, Carmine Pillar, Mme. Abel Carrière, &c.

HOBBIES, LTD., Dereham, Norfolk, showed pillar Roses, *Vitis Henryana*, and large-flowering Clematis.

Messrs. W. CUTBUSH & SON, Highgate, London, N., showed a group of hardy flowers, a number of greenhouse flowering plants, and vases of well-grown Carnations. Among the hardy flowers were a large batch of *Viola Munbyana*, *Hieracium villosum*, *Eremuri*, &c. *Ericas*, *Hydrangeas*, *Calla Elliottiana*, *Verbenas*, *Roses*, &c., were also well shown. (Silver-Gilt Banksian Medal.)

Messrs. R. WALLACE & Co., Kilnfield Gardens, Colchester, exhibited an array of seasonable hardy flowers, amongst which we noticed *Aquilegias*, *Liliums* in variety, gorgeous-coloured Poppies, *Heucheras*, *Pentstemons*, *Eremurus*, *Dodecatheon media*, and its white form; *Cypripedium californicum*, *Dictamnus fraxinella*, &c. (Silver Flora Medal.)

Messrs. BARR & SONS, King Street, Covent Garden, London, W.C., showed rare and choice hardy flowers. Many beautiful "bearded" Irises were noticed, also *Pyrethrums* in variety, the dwarf *Gypsophila cerastioides* (with pale pink flowers that are marked with red lines), *Isirolirion tataricum*, *Anemone Pink Pearl*, the beautiful yellow-flowered *Lilium monadelphum Szovitzianum*, *Brodiaea coccinea*, &c. (Bronze Flora Medal.)

Messrs. GEO. JACKMAN & SON, Woking, Surrey, displayed an array of hardy flowers and Alpine plants. A good batch of the red *Lilium davuricum erectum* was noticed. In the centre of the exhibit were plants of the large-flowered Clematis Lady Northcliffe, with lavender-blue-coloured petals; there were also Irises, *Pyrethrums*, Oriental Poppies, some choice blooms of the yellow *Hemerocallis*, and a host of other pleasing subjects.

Messrs. THOS. S. WARE, LTD., Feltham, Middlesex, filled much table space with garden flowers, all of which were shown in good condition. They had examples of *Melittis melissophyllum*, a large labiate flower with violet lip set in a white perianth; *Linum arboreum*, a very handsome yellow-flowered species; *Ostrowskia magnifica alba*, *Campanula glomerata*, *Pyrethrums*, *Pæonies*, *Irises*, &c. (Bronze Flora Medal.)

Mr. AMOS PERRY, Enfield Chase, Middlesex, showed hardy flowers and plants in great variety. Irises were remarkably fine, and especially good were *I. Susiana*, *I. Lorteti*, *I. sibirica maxima*, and *I. graminea*. Very many Oriental Poppies were included in the exhibit, the colours ranging from very pale pink to the richest scarlet; one of the best is the variety Prince of Orange. Other fine things noticed were *Lindelia spectabilis*, *Nymphaea alba rosea*, *Phlox canadensis*, Perry's variety; *Anthericum liliastrium giganteum*, and *Lilium monadelphum Szovitzianum*. (Silver-Gilt Banksian Medal.)

Messrs. G. BUNYARD & Co., Maidstone, Kent, showed seasonable hardy flowers, amongst which were seen choice Irises, *Pyrethrums*, Poppies, Lupines, *Pæonies*, *Heucheras*, &c. *Papaver pilosum* has petals a fine coppery-red colour: *Baptisia australis* is a leguminous plant

with blue flowers not unlike those of a Lupin. (Bronze Flora Medal.)

Messrs. GUNN & SONS, Olton, Birmingham, showed a number of herbaceous Phloxes. The inflorescences were not so compact as when grown in the open. The selection included Lady Napier, La Soleil, Eclairer, Indian Chief, &c.

Mr. J. FITT, Frythe, Welwyn, showed vases of a double-flowered form of the common Rocket, named *Hesperis matronalis alba plena*. Messrs. GILBERT & SON, Dyke, Bourne, Lincolnshire, had showy Anemones, interspersed with *Aquilegias* and Iceland Poppies. (Silver Banksian Medal.)

J. A. YOUNG, Esq., Stone House, West Hill, Putney (gr. Mr. G. H. Street), exhibited a batch of herbaceous Calceolarias, and another of *Gloxinias*. (Silver Flora Medal.)

Exhibits of Alpine and hardy flowers were also displayed by the Misses HOPKINS, Hillside Nurseries, Barming; Lady NORTHCLIFFE, Sutton Place, Guildford (gr. Mr. Goatley) (Bronze Flora Medal); Mr. MAURICE PRICHARD, Christchurch, Hants (Silver Flora Medal); Mr. G. REUTHE, Keston, Kent (Silver Banksian Medal); Messrs G. & A. CLARK, Dover (Bronze Banksian Medal); The GUILDFORD HARDY PLANT NURSERY Co., Guildford, Surrey; and Messrs. JOHN PEED & SON, West Norwood, London.

Messrs. G. VAN WAVERIN & KRUIJFF, Sasenheim, Holland, displayed two varieties of *Astilbe* (*Spiraea*) with rose-coloured flowers, named Queen Alexandra and Peach Blossom, the former being the deeper coloured.

Mr. CHAS. TURNER, Royal Nurseries, Slough, staged a small group of plants of a new white Carnation named Lady White.

Messrs. J. CHEAL & SONS, Crawley, Sussex, showed their rose-coloured form of the common garden Lupin that now comes true from seeds.

Sir TREVOR LAWRENCE, Burford, Dorking (gr. Mr. Bain), showed a white-spathed *Anthurium* named A. X Lawrenceæ.

Hon. Mrs. EVELYN CECIL, 10, Eaton Place, London, S.W., exhibited a yellow *Gloriosa* from Rhodesia, and other South African plants, including a species of *Arum* from Zululand, and a *Hæmanthus* from the same country.

Messrs. BAKERS, 67, 69, 71, Lichfield Street, Wolverhampton, showed some fine flowers of *Aquilegias* with extra long spurs, and in charming shades of colours.

A very fine strain of these flowers was also exhibited by Messrs. DOBBIE & Co., Rothesay, N.B., and Mark's Tey, Essex.

Messrs. WM. PAUL & SON, Waltham Cross, Herts., exhibited a new dark-red flowered *Rhododendron* named Glory of Waltham. The variety is very floriferous, and the flower trusses are large.

Messrs. CARTER PAGE & Co., 52 and 53, London Wall, London, E.C., showed an assortment of *Fuchsias*, *Zonal Pelargoniums*, and *Cactus Dahlias*, with a few vases of the clear, yellow-flowered *Coreopsis grandiflora*.

Messrs. CANNELL & SONS, Swanley, Kent, showed a group of Cannas, in their usual high standard of quality. Some of the best varieties were Franz von Vecsey, Frau E. Kracht, E. Steinkoff, J. B. van der Schoot, Black Prince, and West Grove. Messrs. CANNELL also displayed *Gloxinias* in very large plants that were carrying numbers of well-developed flowers in the rich colours seen in this showy flower. (Silver Flora Medal.)

Messrs. KELWAY & SON, Langport, Somerset, staged garden *Pyrethrums* in great variety, *Pæonies*, and *Delphiniums*. (Silver Banksian Medal.)

Mr. CHAS. W. BREADMORE, Winchester, showed vases of Sweet Peas of such standard varieties as Helen Lewis, Miss M. A. Linzee (rosy pink), Henry Eckford (orange), Countess Spencer (pink), Nora Unwin (white), and Miss Audrey Crier. (Silver Banksian Medal.)

Mr. H. J. JONES, Hither Green, Lewisham, displayed Sweet Peas, amongst which were many seedling varieties.

Messrs. LIBERTY & Co., Regent Street, London, showed garden pottery in sundials, vases, pedestals, flower-pots, &c., in terra-cotta ware and ornamented with artistic designs in relief.

AWARDS OF MERIT

were recommended to the plants named below:

Davallia brasiliensis, Hort.—Messrs. H. B. MAY & SONS exhibited a plant under this name,

having smooth fronds, with attenuated pinnules. This and other plants have been raised from spores from a specimen introduced from Brazil, where it is found in mountain nooks. In this country the plant succeeds well in the greenhouse, and it should make a good subject for the decoration of the dinner-table. The original specimen, we were told, has fronds 4 feet in length. It is distinct in appearance from other *Davallias*.

Hippeastrum "Mrs. Carl Jay."—If for no other quality, this variety was deserving of the Award for the extraordinary floriferousness the plants exhibited. We noticed in one pot, about 5 inches in diameter, three bulbs, two of which had produced one flower scape each, and the other bulb two flower scapes. Some of these bore six flowers, others seven; therefore, from this small pot there were about 26 flowers and buds. In another respect this *Hippeastrum* is interesting, for the white band along the centre of each leaf clearly indicates that it has been derived partly from *H. reticulatum*, a species whose influence can also be seen to a lesser extent in the flowers. These are veined and netted with rose-pink colour on a white ground, much as in the smaller flowers of *H. reticulatum*, the colouring in places almost suffusing over the intervening spaces of white. The leaves are 2½ inches wide, and the flower scapes grow to a height of about 2 feet. A group of plants were shown in a basket by Mrs. CARL JAY, Blendon Hall, Bexley.

Iris X *Caterina* is a hybrid from *I. cypriana* X *I. pallida*, and is capable of growing to 4 feet in height. The flowers are pale mauve-coloured, except the base of each "fall," which is white marked with brown. The yellow anthers are very effective. The hybrid is one that would be suitably planted in the wilder portion of the pleasure grounds, on banks near to water. Shown by Messrs. BARR & SONS.

Iris "paracina."—This is a pretty little *Iris* obtained from a cross between *I. paradoxa* and an unknown variety. It grows about 18 inches high, and produces flowers of moderate size. The three standards are wholly purple, and the falls are of purple, which is prettily veined with white. It is said to have been raised by Mr. Van Tubergen, Junr., of Haarlem, Holland. Shown by Messrs. BARR & SONS.

Lonicera Maackii.—This hardy Honeysuckle from Eastern Asia was described and figured in our issue for April 27 last (p. 285). Shown by Messrs. JAMES VEITCH & SONS, LTD.

Meconopsis racemosa.—Plants of this Chinese species were shown by Lady NORTHCLIFFE, Sutton Place, Guildford (gr. Mr. Goatley). The plant was mentioned in *Gardeners' Chronicle*, September 17, 1904, p. 198, as growing in Messrs. Bee's nursery at Neston. It is somewhat like *M. aculeata*, but has entire leaves about 4½ inches long, whereas those in *M. aculeata* are lobed. The plants shown were 1½ feet high, and growing in 5-inch pots. The flowers were 2½ to 3 inches in diameter, of deep purplish-blue—almost gentian blue. The stems and leaves were thickly covered with rigid, white or greyish, hair-like prickles.

Syringa Josikaea eximia.—This is a very fine variety of the type, having larger panicles of flowers. Sir TREVOR LAWRENCE, Bart. (gr. Mr. W. Bain), who showed flowering sprays, received the plant from M. Lemoine, of Nancy. This fragrant variety is reddish-rose in colour, and is particularly valuable because it flowers after most of the Lilacs have passed out of bloom.

Orchid Committee.

Present: J. Gurney Fowler, Esq. (in the chair), and Messrs. Jas. O'Brien (hon. sec.), Harry J. Veitch, De B. Crawshaw, H. Little, W. Boxall, R. G. Thwaites, Francis Wellesley, F. M. Ogilvie, J. Wilson Potter, A. A. McBean, H. T. Pitt, A. Dye, W. P. Bound, J. Charlesworth, W. H. Young, H. G. Alexander, W. H. White, H. A. Tracy, F. J. Hanbury, and W. A. Bilney.

Messrs. JAS. & A. A. McBEAN, Cooksbridge, arranged a very beautiful group, in which their speciality of fine forms of *Odontoglossum crispum* was the principal feature. At the back were a number of profusely-bloomed plants of *Oncidium macranthum*, covered with their large bright-yellow flowers, and showing the species probably in better condition than it has ever been seen before. Amongst the forms of white

Odontoglossum crispum were some magnificent varieties, the largest being named Goliath. Of the blotched forms were seen *O. c. Empress of India*, and several others as yet unnamed. Between the specimens of *Oncidium macranthum* were well-flowered examples of *Cymbidium Lowianum* and good *Lælia purpurata*, and others noted included a very fine form of *Vanda Sanderiana*, some fine *Cypripedium bellatulum*, the bright scarlet-coloured *Cochlidia Noezliana*, *Odontoglossum cirrhosum*, and other species. (Silver-Gilt Flora Medal.)

DE B. CRAWSHAY, Esq., Rosefield, Sevenoaks (gr. Mr. Stables), showed a group of rare and well-grown *Odontoglossums*, among which were two plants of the new *Odontoglossum Leo* (Hallii $\times$ triumphans Lionel Crawshay), described in the *Gardeners' Chronicle*, May 25, p. 326; also *O. Souvenir de Victor Hye de Crom*, differing from the original plant of this name in having a clear white labellum; *O. Crawshayanum*, *O. Urania*, *O. bellatulum*, *O. Othello*, two finely-coloured *O. Queen Alexandra*, and other hybrids; good scarlet *Cochlidia Noezliana*, and a magnificent and very dark-coloured form of *O. Harryanum*. (Silver Flora Medal.)

MESSRS. CHARLESWORTH & CO., Heaton, Bradford, had an effective and interesting group, the centre of which was occupied by good specimens of *Thunia Veitchiana*, *T. Marshalliana*, and *Phalenopsis amabilis Rimestadtiana*. The hybrid *Odontoglossums* included the original *O. Phoebe*, and the variety *magnificum*, illustrated in the *Gardeners' Chronicle*, June 1, p. 355. There were also a selection of *Miltonia vexillaria*, *Cochlidia Noezliana*, *Zygopetalum crinitum*, and the beautiful *Z. Roeblingianum*; *Selenipedium caudatum*, *Promenaea xanthina*, with a profusion of pretty yellow flowers; *Dendrobium atro-violaceum*, *Trichopilia crispa marginata*, *Lælio-Cattleya Canhamiana alba*, *Oncidium phymatochilum* and other *Oncidiums*; *Aerides Fieldingii* (seldom seen in such fine flower), various pretty and curious species, including a trailing *Platyclinis* from Java, *Acanthophippium javanicum*, and the rare Indian *Cryptochilus sanguinea*, bearing an inflorescence of bright red flowers, which somewhat resemble those of the lesser *Tillandsias*. (Silver Flora Medal.)

MESSRS. SANDER & SONS, St. Albans, staged an attractive group, in which the beauty and variety of their "Rex" forms of *Lælio-Cattleya Canhamiana* was well displayed, the colours varying from white with crimson labellum, to rosy-lilac with reddish-purple lip. With them were a pretty selection of hybrid *Phaius*, including *P. Phoebe* and *P. Cooksoniae*, both showing the pleasing form of *P. Humboldtii* in the lip; a very fine blue *Vanda cœrulea*, *Lælio-Cattleya Bertha*, the large cream-white and claret-coloured *Maxillaria Sanderiana*, *Brassia verrucosa*, *Odontoglossum cordatum*, and other *Odontoglossums*; a fine specimen of *Dendrobium Falconeri*, another of the handsome *Odontoglossum crispum-Harryanum* of the Brugense class, various *Cypripediums*, &c. (Silver Flora Medal.)

MESSRS. HUGH LOW & CO., Enfield, arranged a showy group composed principally of *Cattleya Mossiae* and *C. Mendelii*. Among the former was a fine specimen of *C. Mossiae* "Queen of Denmark" of the *C. M. aurantiaca* class, and similar to the old-time favourite *C. M. McMorlandii*, the lip being, save the whitish-crimped margin, of a bright chrome yellow colour. There were also several white forms of *Cattleya Mossiae*. *C. Mendelii* was shown in great variety, but chiefly of the mauve-purple-lipped class. Others noted were *C. intermedia alba*, *Calanthe veratrifolia*, *Dendrobium Bensoniae*; a batch of *Vanda teres*, two distinct forms of *Cœlogyne Massangeana*, with shorter and denser racemes of flowers than the original; the pretty light-coloured *Lælia purpurata Lowiae*, &c. (Silver Flora Medal.)

MESSRS. STANLEY & CO., Southgate, displayed a group of *Cattleya Mossiae* of excellent quality, some of the plants having exceptionally large and richly-coloured flowers. The white *C. Mossiae Fieldiae* has chrome-yellow markings on the lip, in front of which are a few pale-purple lines. (Silver Flora Medal.)

R. I. MEASURES, Esq., Cambridge Lodge, Camberwell (gr. Mr. Smith), had a small group of exceptional interest, and including more than forty species and varieties. The *Masdevallias* included *M. tridactylites*, *M. xanthocorys*, *M.*

muscosa, varieties of *M. ignea*; *M. Lindenii*, forms of *M. Chimæra*, and others. The groups also contained two plants of the rose-purple *Saccolabium ampullaceum*, the orange-coloured *S. curvifolium*, *Restrepia elegans*, *Pleurothallis ornata*, *Cypripedium callosum Sanderæ*, *C. seligerianum majus*, *C. Curtisii*, *Lælia purpurata*, &c. (Silver Banksian Medal.)

H. S. GOODSON, Esq., Fairlawn, Putney (gr. G. E. Day), sent *Cattleya Mossiae* King Edward VII., a fine dark variety, having a close resemblance to a good form of *C. labiata*; the sepals and petals were of a purplish-rose colour, and the front of the lip was deep crimson. Mr. GOODSON also showed *Lælia purpurata* "Fairlawn," a light variety; and *Cymbidium Huttonii* "H. S. Goodson," a variety with a raceme of yellowish flowers that are densely spotted with blackish-purple.

FRANCIS WELLESLEY, Esq., Westfield, Woking, showed *Cypripedium Lawrenceanum* "Purple Emperor," a very richly-coloured form approaching the variety *Hackbridgense*, and with a decided purple shade over the labellum and the rose crimson-tinted dorsal sepal which bears dark chocolate-purple lines from the emerald green base to the margin; also the beautiful *Cattleya Mendelii* "Francis Wellesley." (See Awards.)

Major G. L. HOLFORD, C.I.E., C.V.O., Westonbirt, Tetbury (gr. Mr. H. G. Alexander), displayed *Cattleya Mendelii* *delicata*, a large and finely-formed blush-white flower, with a chrome-yellow disc to the lip, which also has a distinct light-purplish blotch in the front.

MESSRS. JAS. VEITCH & SONS, Royal Exotic Nursery, King's Road, Chelsea, sent two specimens of *Brassia-Lælia Digbyano-purpurata*, and one of the yellow, rose-tinted *Sobralia Veitchii*.

G. D. BAILEY, Esq., Roseleigh, Burgess Hill, sent a good specimen of *Bifrenaria Harrisoniae alba*, with several flowers.

AWARDS.

FIRST-CLASS CERTIFICATES.

Miltonia vexillaria chelisiensis superba, from Major G. L. HOLFORD, C.I.E., C.V.O., Westonbirt (gr. Mr. H. C. Alexander). A very distinct and large-flowered form, and the best of the *M. v. radiata* class. The flowers are broadly-ovate in outline, and are of a delicate Peach-blossom tint, the bases of the petals being rose colour. The broad, triangular mask at the base of the lip is composed of several confluent lines of a claret-crimson colour, the central one being the longest. There are also three similarly coloured lines on the lower half of the petals. The plant shown was a finely-grown specimen with four flower-spikes—three bearing five flowers each, and one four flowers.

AWARD OF MERIT.

Cattleya Mendelii "Francis Wellesley," from FRANCIS WELLESLEY, Esq., Westfield, Woking (gr. Mr. Hopkins). A charming and delicately-tinted flower of large size and of perfect form. The flowers are white, with a slight suffusion of blush-pink. The base and disc of the lip has chrome-yellow lines, and the front has a slight freckling of rosy-lilac. The plant is a robust grower and carried several finely-developed flowers.

Fruit and Vegetable Committee.

Present.—Geo. Bunyard, Esq. (chairman), and Messrs. W. Bates, Geo. Woodward, A. Dean, H. Parr, A. R. Allan, Ed. Beckett, R. Lye, Jas. Vert, H. Markham, Jno. Lyne, Geo. Kelf, P. D. Tuckett, Owen Thomas, W. Poupart, Geo. Reynolds, and J. Davis.

The principal exhibit before this committee was a collection of about three dozen Melons in seven varieties and one seedling, shown by Lady NORTHCLIFFE, Sutton Place, Guildford (gr. Mr. Goatley). The fruits were a fine sample, and included Ringleader, Hero of Lockinge, Superlative, The Peer, &c., and they were interspersed with small foliage plants. (Silver-Gilt Knightian Medal.)

Miss C. M. DIXON, Elmcroft Nursery, Westergate, Chichester, showed several fruits of a yellow-skinned, netted Melon named Swanley Horticultural College Seedling. (Silver Banksian Medal.)

Mr. S. MORTIMER, Rowledge, Farnham, Surrey, showed boxes of a dark-skinned Cucumber named Market Rival. The fruits were an excellent sample, about 18 inches in length, somewhat thick, and with a tapering "handle."

ROYAL BOTANIC.

JUNE 12, 13, 14.—An interesting exhibition of plants and cut flowers was held on the above dates in the gardens of the society, Regent's Park.

MESSRS. PAUL & SON, Waltham Cross, made a fine display of Roses growing in pots and as cut bloom; climbing varieties and forms of *Rosa polyantha* formed the more entrancing objects in the group, and we noted fine flowered examples of Wedding Bells, Crimson Rambler, Lady Gay, Debutanté, Rubra, Waltham Rambler, Waltham Bride, Kathleen, and Sweetheart, and the single-flowered white Rose Nymph. Hybrid Perpetuals, such as Spenser, Merveille de Lyon, A. Colomb, Etoile de France, Ella Gordon, Baroness Rothschild, Crimson Queen, and Teas and Hybrid Teas Mme. de Watteville, Beatrice, Souvenir du President Carnot, Earl of Warwick, Celina, Maman Cochet, and Tennyson, made up the major portion of the exhibit. The plants showed their beauties well enough individually, but there was something wanting to make the group effective as such; perhaps there was too much bloom and no foliage other than that of the Roses to serve as a foil. (Large Gold Medal.)

Mr. GEO. MOUNT, Exotic and Rose Nurseries, Canterbury, exhibited extensively climbing Roses, such as Hiawatha, Leuchtstern, Lady Gay, Crimson Rambler, &c. The finest features of the exhibit were the cut blooms, especially fine being those of Ulrich Brunner, Frau Karl Druschki, Mrs. John Laing, Caroline Testout, Richmond, Captain Haywood, and Mrs. Sharmar Crawford. Many other varieties were shown of fine quality, and in great numbers. (Large Gold Medal.)

Mr. S. MORTIMER, The Nurseries, Rowledge, Farnham, exhibited American Carnations in fine form. We noted Lady Bountiful, a large frimbriated white flower; Nelson Fisher, similar in form, and of deep rose-pink colour; America, a regularly formed bloom, bright scarlet in tint; Thos. W. Lawson, Fair Maid, Norway, and other beautiful varieties.

Mr. MORTIMER also showed a new Cucumber Market Rival, a handsome, dark-green, spineless fruit, 18 inches long. (Large Silver Medal.)

MESSRS. G. JACKMAN & SONS, Woking Nursery, Surrey, showed a large collection of Iris in variety, a few well-bloomed plants of Clematis Lady Northcliffe, a large single-flowered novelty; many varieties of Pyrethrum roseum, Papavers, including Princess Victoria Louise, a cherry-red, semi-double flower, &c. (Large Silver Medal.)

MESSRS. HUGH LOW & CO., Bush Hill Nurseries, London, N., showed Carnations, English, American, and Souvenir de la Malmaison varieties. The English-raised Carnation Britannia, of a scarlet colour, was shown in fine form; also Leander, Fiancée, Princess of Wales, a "Malmaison" of light rose tint; and Mrs. Burnett, of a soft rose colour, and with slightly dentate edges. The collection was rich in "Malmaison" varieties, and the striped Sir Evelyn Wood was extremely well shown, also the pure white Nell Gwynne, and pink-coloured Baldwin. A specimen plant of "Malmaison" Princess of Wales possessed 56 flowers and buds. Some well-flowered plants of *Callistemon floribunda* were noted in this collection. (Gold Medal.)

MESSRS. JOHN PEED & SON, West Norwood Nurseries, showed miscellaneous border plants in large numbers, including Iris and Pyrethrums, in great variety. Gloxinias in innumerable variety of colour, and all of the erect type, were also shown by Messrs. PEED. (Silver-Gilt Medal.)

MESSRS. THOS. WARE & CO., LTD., Feltham, showed a comprehensive collection of hardy perennials as cut blooms, and small plants, Iris, Papaver, Pyrethrum, and Pæonia being the more conspicuous species. (Silver-Gilt Medal.)

Mr. H. CRANE, Highgate, a well-known grower of Violas and fancy Pansies, showed 36 bowls full of blooms of these plants. (Silver Medal.)

Mr. M. PRICHARD, Christchurch, Hants, showed hardy perennials as cut bloom, Eremuri, Irises, and Pyrethrums being the chief subjects. (Large Silver Medal.)

A fine and varied collection of Sweet Peas came from Mr. C. W. BREADMORE, Winchester, the flowers being large and of good substance. There were many varieties having charming colours and tints among them. (Gold Medal.)

HOBBIES, LTD., Dereham and London, showed a number of Rambler and Polyantha Roses arranged as a group for effect. (Silver Medal.)

Mr. C. F. WATERS, Deanland Nursery, Balcombe, Sussex, exhibited Carnations of all types in a rich collection containing the latest novelties amongst these flowers. (Large Gold Medal.)

Mr. AMOS PERRY, Hardy Plant Farm, Enfield, showed large-flowered Papavers and Pyrethrum roseum in variety; a good variety of Papaver orientale is Mrs. Perry, a single-flowered variety, with satiny-pink petals that have a black blotch at the base. The new single-flowered variety Princess Ena was likewise shown. It has small cup-shaped flowers of a salmon-pink tint. Iris pallida, a new cross between I. iberica and I. pallida, was observed here. (Silver-Gilt Medal.)

Mr. G. REUTHE, Keston, Kent, showed a large miscellaneous collection of hardy perennials as cut bloom. Flowering shoots of Embotrium coccineum and Rhododendron cinnabarinum were included in the exhibit. (Silver-Gilt Medal.)

Mr. R. RASMUSSEN, Eastville Nurseries, Waltham Cross, showed Petunias in wonderful variety. (Large Silver-Gilt Medal.)

Mr. G. & A. CLARK, of Dover, showed Pyrethrum roseum, both single and double-flowered varieties; Iris in variety, and miscellaneous hardy perennials as cut bloom; the exhibit was a collection rich in good plants. (Silver Medal.)

Messrs. BARR & SONS, King Street, Covent Garden, showed Japanese pygmy trees, Conifers and Acers; also hardy flowers, including Irises Pyrethrums, and miscellaneous hardy perennial plants as cut bloom. (Gold Medal.)

ED. WAGG, Esq., The Islet, Maidenhead (gr. Mr. D. Phillips) showed a number of Souvenir de la Malmaison Carnation Princess of Wales, almost as many of C. Cecilia, a lemon-yellow coloured flower and tall grower, and Calypso, a pale flesh-tinted variety. (Gold Medal.)

Messrs. T. S. RIVERS & SON, Sawbridgeworth, Herts, showed some well-fruited trees of Nectarines, Peaches, Plums, Cherries, including the new Peaches Duke of York and Peregrine. (Gold Medal.)

S. HEILBUT, Esq. (gr. Mr. G. Camp), The Lodge, Holyport, Maidenhead, showed a splendid collection of fruit trees in pots. (Gold Medal and Special Prize.)

COLONIAL EXHIBITS.

South Australian produce.—Exhibited by the AGENT-GENERAL FOR SOUTH AUSTRALIA, Threadneedle House, London, E.C. This exhibit consisted of red and white wines in bottle, honey in the run state, Apples and Pears of large size, fine colour, and clear in the skin. The fruits were exclusively dessert varieties. We tasted a fruit of Winter Nelis, and found it to be excellent. There were specimens of Mme. Cole, Broom Park, and one other Pear without a name. Among Apples we noted Strawberry Pippin, Shortland's Eclipse, Prince Alfred, Scarlet Nonpareil, Schröder, Hoover, Esopus Spitzbergen, Northern Spy, Dunn's Seedling, Stone Pippin, and Garibaldi, also a dish of large Quinces.

An exhibit of wines from South African vineyards was made by Messrs. J. SEDGEWICK & Co., colonial wine and spirit merchants and distillers, of Cape Town, whose London agents are Messrs. JEREMIAH LYON & Co., 4, Lombard Court, E.C.

Messrs. R. JACKSON & Co., direct importers, 172, Piccadilly, London, W., had an interesting exhibit of South African products. There were preserved fruit as whole fruits and as jams and jellies, jams from the Cape Gooseberry; from Plums, Green Figs, Grape, Pineapple, Peach, and other fruits. Natal tea is another product of South Africa sold by this firm that is making its way in this country, selling at 1s. 10d. per lb. It is intermediate between the Chinese and Indian teas.

THE HORTICULTURAL CLUB.

"OUR WONDERFUL WORLD."

JUNE 11.—The final meeting of the season was held at the Hotel Windsor on the above date, and, after the usual dinner, at which Mr. Harry J. Veitch presided, Mr. Chas. T. Drury, V.M.H., F.L.S., read a paper entitled "Our Wonderful World." In this paper Mr. Drury condensed a description of the earth's origin, taking the nebular hypothesis for granted, and divided his discourse into four headings—the

Earth, the Aerial Ocean, the Aqueous Ocean, and the Life which exists in and upon all three. Handling so inexhaustible a theme in this way, he was enabled to give, in treating each section, a glimpse of the wonders involved in geological records, which demonstrate beyond doubt the most incredible changes of scene within the same area, citing as an instance the chalk hills of Kent and the coal formations below them as testifying to the existence at different periods at the same place of immense forests, an ocean, and now of a broad prospect of hill and dale, which was once that ocean's bed. The aerial ocean, at the bottom of which we live, has its points of similarity with the watery ocean in its currents and whirlpools represented by winds and cyclones. The gaseous composition of both air and water was described, and the wonderful differences brought about by different conditions of gaseous admixtures alluded to, the very air we breathe being a mixture of precisely the same gases oxygen and nitrogen as constitute that most corrosive acid (nitric acid), while the innocuous nitrogen of the air, a mere diluent of the too active oxygen, is the basis of the most powerful explosives.

It was, however, the life in our wonderful world which appealed most to one's sense of the marvellous, and the lecturer demonstrated how the history of the cell, the basis of life, tended to support the doctrine of evolution, the chain of progress being repeated in every individual. Nor were we only indebted to cell action for our own existence and that of all other organic life, but the by-products, as it were, formed the bulk of our surroundings, providing the materials by which we are fed, clothed, and, to a large extent, housed. Even our thoughts, he pointed out, and all that thought leads to in the way of invention, etc., are due to subtle cell activity in our brains, the culmination, as it were, of the wonders involved in creation generally. The lecturer concluded with some lines written by him nearly 40 years ago.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

JUNE 10.—The monthly committee meeting of this society was held at the Royal Horticultural Hall, Vincent Square, Westminster, on the above date. Mr. Charles H. Curtis presided, and five new members were elected, making a total of 49 this year. The stocks of the society have been duly transferred from the old to the new trustees. Sympathy and condolence were expressed with the widow and family of the late Mr. George Wheeler, who was one of the original members of the society, and had held the office of trustee for 31 years, and from which he had just retired.

ELAÏS GUINEENSIS VAR. LISOMBE.—This variety of the oil Palm, as we learn from the *Gartenflora* for May 15 last, in a report of the Prussian States Horticultural Society's meeting on April 21, was discovered several years ago by the celebrated African traveller and collector, Professor Dr. PREUSS, in the Lisombe forest in the Cameroon territory, and was introduced to the Botanic Garden at Victoria, of which he was earlier the director. It was stated at the meeting by HEN. KLAR that the seeds are ground, and the oil thus obtained smells very strongly of Violets, and is consumed as food and also made into soap (Elaine). This new introduction is in every particular better, and in oil production more abundant, than the common oil Palm. The demand for the seeds is considerable, but the supply is at the present time small; moreover, the variety is not in commerce. The British Colonies are almost exclusively supplied by the ordinary oil Palm tree, and that most abundantly. In appearance the seeds of the new variety do not differ from those of the type.

CATALOGUES RECEIVED.

JAMES DYSON & Co., Atlas Works, Elland—Dyseleine Insecticide.

FOREIGN.

JULIUS ROEHRS Co., Exotic Nurseries, Rutherford, New Jersey—Orchids, Stove and Greenhouse Plants, and Nursery Stock.

THE WEATHER.

THE FOLLOWING SUMMARY RECORD of the weather throughout the British Islands, for the week ending June 8, is furnished from the Meteorological Office:—

GENERAL OBSERVATIONS.

The weather was generally cloudy or overcast, with frequent and sometimes heavy rain in the northern and western districts, and with occasional slight falls in the south and south-east. Thunderstorms occurred over a large part of England on Wednesday, and in some places on Thursday, while at Swaraton thunder was heard both on Tuesday and Friday, and at Chester a thunderstorm was experienced at the commencement of the week.

The temperature was again below the average, the defect ranging from rather more than 1° in England E. to about 8° in several other English districts and in Ireland N., and to more than 4° in Scotland N. and E. The highest of the maxima were mostly recorded on Saturday, and ranged from 70° in the Midland Counties to 64° in Ireland N. and Scotland E., and to 68° in Scotland W. During the early days of the period some of the maxima were again below 60° in the north. The lowest of the minima, which occurred during the earlier half of the week, varied from 38° in the north and east of Scotland to 44° in Ireland S., and 48° in the Channel Islands. At some of the Scottish stations and at Cockle Park, Morpeth, the thermometer on the grass fell to 30° or 31°.

The mean temperature of the sea.—The water was rather colder than during the preceding week on nearly all parts of the coast, the loss of heat being more than 1° at some Scottish stations and 0·8° at Margate. The mean temperature ranged from 55° at Newquay and 54·6° at Eastbourne to about 48° off the east of England, and to less than 45° on the coasts of Scotland and north-eastern England. The lowest reading was 45·8° at Burnmouth.

The rainfall was less than the average over eastern, central, and southern England, and also in the English Channel; elsewhere it was above it, the excess being very large in the western and northern districts. On the 2nd and 5th a fall of 1 inch was measured at Stonyhurst, and on the 4th a similarly large fall occurred at Aspatia.

The bright sunshine was less than the average in all parts of the kingdom. The percentage of the possible duration was only 8 in England N.W. and Scotland W. and 13 in Scotland N.; elsewhere it ranged from 15 in Scotland E. to 27 in England S., and to 30 in the English Channel.

THE WEATHER IN WEST HERTS.

Week ending June 12.

Frequent showers. The days have been, as a rule, somewhat cool for the time of year, while the night readings have been, on the contrary, mostly rather above the average. On the warmest day of the week the temperature in the thermometer screen rose to 73°, and on the coldest night the exposed thermometer fell to within 5° of the freezing point. The ground is not now so cold as it has lately been, being both at 1 and 2 feet deep only 1° colder than is seasonable. Rain fell on all but one day, and to the total depth of three quarters of an inch. On the 5th inst., during a brief but very heavy shower, the rain was falling for a minute at the very exceptional rate of 8 inches an hour. Percolation through both soil gauges still continues. Since the beginning of the month about two gallons of rain-water has come through both gauges. The sun shone on an average for 6½ hours a day, which is about a seasonable duration for the middle of June. The wind has been moderately high throughout the week, and has come almost exclusively from some point between south and west. The mean amount of moisture in the air at 8 p.m. was 1 per cent. less than a seasonable quantity for that hour. A large bush of the wild Dog Rose came into flower in my garden on the 7th inst., which is two days later than the average for the previous 21 years, and the same date as last year. E. M., Berkhamsted, June 12, 1907.

DEBATING SOCIETIES.

WARGRAVE AND DISTRICT GARDENERS'.—The last meeting of this association of the season was held on Wednesday, May 29, when Mr. H. Stoten, of Bearwood Gardens, read a short paper on "The Culture of the Persian Cyclamen." Cultural directions, including advice on seed sowing, suitable soils, potting, manuring, and pests were carefully dealt with in the paper.

BRISTOL AND DISTRICT GARDENERS'.—The first meeting of the summer session of this association was held on Thursday, May 30, when W. E. Budgett, Esq., presided over a good attendance. The subject of the lecture was "Alpine Plants," the lecturer being Mr. J. C. House, Westbury-on-Trym, who staged many Alpine plants to illustrate his remarks. To those persons about to build a rockery, he suggested a visit to Clifton Downs, for the purpose of obtaining a lesson from nature in the manner of constructing a rock-garden. Mr. House gave advice on the management of Alpine plants and gave a list of those that should be frequently moved and others that should not be disturbed; he also mentioned subjects suitable for sunny, shady, and moist positions, and gave the names of suitable shrubs for planting between them. Mention was made of the pretty little *Scilla autumnale*, some plants of which were given by a lady to Mr. Brunel, the noted engineer, who, when building Clifton Suspension Bridge, planted them in an almost inaccessible part of St. Vincent's Rocks, where they are still growing. H. W.

SCHEDULES RECEIVED.

LYDNEY HORTICULTURAL AND COTTAGE GARDEN SOCIETY'S 2nd annual exhibition to be held in the Lydney Town Hall, on Saturday, July 27, 1907.

CAMBRIDGESHIRE HORTICULTURAL SOCIETY'S summer show to be held on Tuesday, July 9, in the Fellows' Gardens, Trinity College, Cambridge, and autumn show to be held in the Corn Exchange, Cambridge, on Wednesday and Thursday, November 6, 7.

MARKETS.

COVENT GARDEN, June 12.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—Ed.]

			Watercress, per doz. bunches	0 4-0 6	

REMARKS.—The largest shipment of Australian Apples received this season arrived during the past week, and in consequence prices for most varieties are considerably lower. French Cherries are now very plentiful and much cheaper. English Tomatoes are seen in increased quantities, and prices realised are lower than those of most previous

years at a corresponding season. A good demand exists for best home-grown Strawberries; a large quantity of inferior fruits of Strawberries are seen, but they have practically no demand. P. L., Covent Garden, Wednesday, June 12, 1907.

POTATOS.

Blacklands, 85s. to 95s.; Lincolns, 100s. to 110s.; Yorks, 100s. to 115s.; Scotch, 100s. to 110s.; Dunbars, 110s. to 120s.; Dutch (bag), 4s. to 4s. 6d.; German (bag), 4s. 6d. to 5s.; Jerseys, 7s. to 7s. 6d. per cwt.; St. Malo, 7s.; Tenerife, 7s. to 8s. The trade is normal for the season. W. J. C. & S., Covent Garden, June 12, 1907.

COVENT GARDEN FLOWER MARKET.

Large supplies of most plants are still seen, but stocks of a few things are short, and care is needed in accepting orders for some plants. Large quantities of Hydrangeas are seen, and this morning many were left unsold, especially plants of H. Hortensia. The variety Thos. Hogg is not quite so plentiful, but H. paniculata grandiflora is taking its place. Rambler Roses are of good quality, but they do not clear well. Some very good plants of hybrid perpetual Roses are to be had, and dwarf Polyantha varieties are well flowered. Lilium longiflorum may be procured in pots from 8 inches up to those containing three or four bulbs and measuring 8 inches. Marguerites may be had in all sizes; those grown for decorative purposes are now very good, and young plants for window boxes and bedding purposes are of the best quality. Standard Fuchsias are plentiful this season. Zonal Pelargoniums may be had in all the leading sorts, in well-flowered plants; the Ivy-leaved and the show varieties are also well supplied. The new double-flowered Lobelia is more suited for edging flower-beds than for window-box decoration, but well-flowered pot plants would command a sale. Growers often spoil the trade for a new plant through being in too great a hurry in marketing it. Yellow Calceolarias are good. Intermediate Stocks are now practically over for the season. Both single and double varieties of Chrysanthemum segetum are seen in well-flowered plants. A few good Yellow Marguerites are procurable. There is but little variation in supplies of foliage plants. Trade generally is uncertain for all pot plants.

CUT FLOWERS.

Supplies are still over abundant. Best Roses clear out fairly well and Carnations have a rather better demand, the Malmaisons are now very good, but prices for these flowers are much lower when compared with those of a few years ago. The very finest are certainly dear, but flowers of second quality are difficult to dispose of for satisfactory prices. The double white Narcissus may be finished at any time now. Spanish Irises are good and plentiful. Herbaceous Pyrethrum are coming from some growers in wagon loads, and they include some of the finest varieties of both single and double forms. Gladiolus Colvillei alba, and also the hybrid varieties are good. Sweet Peas are abundant, and only those of best quality and with long stems are valuable. Tulips are nearly over for the season, which has lasted for fully seven months. One grower exhibited a bunch of Chrysanthemums for sale a morning or two since. A. H., Covent Garden Market, June 12, 1907.

Obituary.

ERNEST A. CANNELL.—We regret to record the death on Tuesday, 4th inst., of Mr. ERNEST A. CANNELL, youngest son of Mr. HENRY CANNELL, Swanley. The deceased gentleman was an active member of the firm of Messrs. CANNELL & Sons, and he devoted much time to the development of the Cockmanning Nurseries of the firm at St. Mary Cray. The late Mr. CANNELL, who was 40 years of age, was engaged in the business until within a few hours of his death. He leaves a widow and two children.

ANSWERS TO CORRESPONDENTS.

* * * The Editor will be glad to receive, for consideration, large photographs of horticultural subjects, suitable for forming Supplementary Illustrations to this Journal.

APPLE SHOOTS CURLED: J. T. S. The effect of injury by frost followed by bright sun killed one side of the imperfectly ripened shoots; the opposite side continued to grow and thus caused the twisting.

ASTERS DISEASED: F. E. S. & Co. The seedlings arrived in a dead and shrivelled condition, and were not sufficiently fresh to enable the cause of their failure to be determined.

BOOKS: A. B. The Glossary of Botanic Terms is not an illustrated work. It is a list of botanical terms and not of plant names. The Botanical Dictionary, by Sir Joseph Paxton, is out of print, and can only be obtained from the second-hand booksellers. The best garden dictionary is Nicholson's Dictionary of Gardening: a cheaper but good work is Johnson's Gardeners' Dictionary. Both of these books may be obtained from our publishing department.—Weekly Reader. Begonia Culture, by B. R. Ravenscroft, will suit your purpose. This work can be obtained from our publishing department, price 1s. 2d., free by post.

BULBS FOR FORCING: A. R. B. If you have the use of the houses from November to March only, we doubt if it is wise for you to force Irises at all. Had you the use of frames in addition to the continuous use of the houses the Iris crop would come in useful enough as a succession to the earliest forced Daffodils. Irises cannot be successfully forced in the ordinary way because they require a long season of preparation. The boxes will do quite well and are more satisfactory for the purpose than any other receptacle. Bulbs planted below ground in the greenhouse are of little value for purposes of early forcing, and remain far too long uninfluenced by the internal conditions of the house. A frame, or frames, beside the greenhouses on the south side, would be best for the Iris crop till early in February, at which time the greenhouse and the temperature you name (50°) would prove suitable. It is impossible to say whether these would be more remunerative than last year's crop, for no two seasons are alike in this respect. There should be more profit on the large number of bulbs you forced, but, although we know the dates on which they flowered were moderately early, you do not state whether or not the bulbs flowered satisfactorily. We think that either many bulbs failed to flower or the quality was not first class. Had you given us some idea of the manner in which the houses are heated and the average temperature that can be maintained in winter we might have suggested other plants, Tulips for example. Tulips, however, when used for early forcing succeed best when bottom heat is afforded. In no case would Irises prove good substitutes for early Narcissus. We would suggest Hyacinths as a catch crop rather than as a primary one.

DANDELIONS: G. S. You did wrong to allow the plants to seed: they should have been mown down before they reached the seeding stage. Perhaps you have no power to mow over the adjoining fields, in which case we are afraid you can do nothing but exterminate the seedlings as they appear in your garden.

FOLIAGE PLANTS AT AN EXHIBITION: F. L. The Cycads and the Palms are quite distinct, and you need have no fear of entering a Cycas in your exhibit along with a Palm.

HOLLY: T. B. D. & Co. The variety of Holly appears to be similar to that known as *negrescens*. We are unable to explain why birds avoid the berries.

LABURNUM ADAMI: J. J. F. There is nothing very unusual in your specimen of this tree bearing three kinds of flowers, although it is true, as you say, that the production of only two kinds is more common. Besides the ordinary flowers of the hybrid *L. Adami* your tree is also bearing the flowers of the two parents, viz., the common Laburnum (yellow) and *Cytisus purpureus* (purple). We have noticed a tree in the Royal Botanic Gardens at Kew which for some years past has regularly borne the three sorts of flowers (see note and illustration in *Gardeners' Chronicle*, September 24, 1904, p. 217.) The double-flowered form of *Prunus triloba* does occasionally form young fruits like those you send, but we think you will find that they will soon drop off. We, at any rate, have never known such fruits to attain maturity.

LAWN: F. J. H. A good turf is not to be had in a season or two from the sowing of the seed. It will need careful mowing and rolling, and then in time the fine matting of roots and stem will give the springy sward desired. The application of a mulching of manure in the autumn, and small doses of artificial manures now the grass is growing freely will all tend to stimulate and strengthen the grass.

MANURE FOR CARNATIONS: Dunsland Carnations will succeed in any ordinary soil, from light, sandy loam to a firm clay, but they prefer a moderately rich loamy soil. A compost consisting of well-rotted turf with one-fourth its bulk of decomposed manure, adding $\frac{1}{2}$ bushel of air-slacked lime and $\frac{1}{2}$ bushel of wood ashes to every load of soil, would be very suitable. If the turf used is from a clayey soil, horse droppings are recommended; if from a light, sandy soil, use cow manure. For a medium class of soil use a mixture of horse and cow manure. It is certain that Carnations thrive better in every way in fresh or virgin soil. No potting material can beat fresh loam obtained from the top

spit of a pasture. Out-of-door beds should be prepared in September by trenching the soil to a depth of 18 inches. The soil of the first trench is thrown out, and the bottom or subsoil broken up, then a good layer of cow manure and a sprinkling of superphosphate is put in, the top spit of the next trench being turned on the manure. At the same time keep a sharp look out for wire worm, which is one of the worst enemies of the Carnation. Add another layer of cow manure and superphosphate, and so on as the work progresses. With the fine soil incorporate some lime rubbish and soot. The soil recommended for pot culture is two parts fibrous loam and one part well decomposed leafmould, with a good sprinkling of sand. Apply a good watering after the potting is done and plunge the pots into cocoa fibre or coal ashes in a cold frame, keeping the plants as near to the glass as is practicable. Carnations should not be over-fed with manures, nor grown in an excessively heated atmosphere, for if this is done the constitution of the plants becomes impaired, and disease quickly sets in. All varieties of these plants require a lasting, rather than a forcing manure; that is, one which becomes available slowly but regularly. For pot culture use a little bone meal or horse hoof parings from a shoeing shop if you can get them. If the plants look weakly add $1\frac{1}{2}$ oz. of nitrate of potash (saltpetre), to each gallon of water and apply this once a week.

MELON ROOT: T. M. G. The roots you send were badly infested with eel-worm. All the old soil in which they have been grown should be turned out of the house and sterilised by burning. The surroundings in the Melon pit should be thoroughly drenched with a solution composed of carbolic acid in the proportion of one part to twenty of water.

NAMES OF FLOWERS, FRUITS AND PLANTS.—We are anxious to oblige correspondents as far as we consistently can, but they must bear in mind that it is no part of our duty to our subscribers to name either flowers or fruits. Such work entails considerable outlay, both of time and money, and cannot be allowed to disorganise the preparations for the weekly issue, or to encroach upon time required for the conduct of the paper. Correspondents should never send more than six plants or fruits at one time: they should be very careful to pack and label them properly, to give every information as to the county the fruits are grown in, and to send ripe, or nearly ripe, specimens which show the character of the variety. By neglecting these precautions correspondents add greatly to our labour, and run the risk of delay and incorrect determinations. *Correspondents not answered in one issue are requested to be so good as to consult the following numbers.*

PLANTS: *Primula*, *Primula cortusoides* ("Sieboldi").—*E. R. F.* 1, *Saxifraga tricuspidata*; 2, *S. species*; 3, *S. hirta*; 4, *S. muscoides*.—*Hugh Aldersey*. 1, *Erodium hymenodes*; 2, *Saxifraga lingulata*; 3, *S. cotyledon var.*; 4, *S. Aizoon*; 5, *S. Hostii*; 6, *S. elatior*.—*E.* 4, *Baptisia australis*.—*J. W. H.* 1, *Lonicera*, sp. near *L. xylostemon*; 2, *L. tatarica var. punicea*; 3, *Spiraea cantoniensis*; 4, *Lonicera involucrata*; 5, *Viburnum Opulus*; 6, *Magnolia acuminata*.—*E. D. L.* 1, *Fritillaria pyrenaica*; 2, *Clematis montana*; 3, *Cryptomeria japonica*; 4, *Sequoia sempervirens*; 5, *Abies cephalonica*; 6, *Picea excelsa pygmaea*.—*A. B.* 1, *Rosa spinosissima var. altaica*; 2, *Acer japonicum var. filicifolium*; 3, *Leucothoe Catesbaei*; 4, *Cornus alba*; 5, *Berberis Aquifolium var. macrophylla*; 6, *Caragana arborescens*.—*F. J., Hants.* 1, *Fraxinus Ornus*; 2, *Spiraea Van Houttei*; 3, *Kerria japonica fl. pl.*; 4, *Spiraea arguta*; 5, *Picea orientalis*; 6, *Juniperus chinensis*; 7, *Spiraea prunifolia fl. pl.*.—*S. P.* 1, *Distylium racemosum variegatum*; 2, *Cotoneaster buxifolia*.—*T. The flowers were quite over when received, and as the class is so numerous it is difficult to name them correctly, even from good blooms.—*N. G., Wales.* 1, *Oncidium prætextum*; 2, *Oncidium crispum*.—*L. E. W.* *Dendrobium fimbriatum*.—*V. I. M.* 1, *Selaginella levigata*; 2, *Pteris longifolia*; 3, *Adiantum assimile*.—*H. L. M.* 1, *Pyrus Aria*; 2, *Geranium pratense*; 3, *Geum coccineum*; 4, *Mespilus germanica (Medlar)*; 5, *Arbutus Unedo*; 6, Not recognised, send when in flower. —*F. W. J.* 1, *Geum grandiflorum* (very fine form);

2, *Veronica*, send when in flower; 3, *Begonia Arthur Malet*; 4, *Cyperus longis*; 5, *Begonia incarnata*; 6, *Pteris cretica var. Wimsettii*.—*T. P.* 1, *Odontoglossum citrosomum*; 2, *Brassia verrucosa*.—*W. C. P.* The sorrel is *Rumex Acetosa*; 2, *Lepidium Smithii*.—*H. C.* *Fraxinus Ornus*.—*F. W.* 1, *Agathæa celestis*; 2, *Cedronella triphylla* (Balm of Gilead); 3, probably *Diplacus glutinosus* (no flowers); 4, send in flower; 5, *Eupatorium Weinmannianum*; 6, *Cassia corymbosa*; 7, *Anthericum lineare variegatum*.—*Defiance.* 1, *Potentilla variabilis*; 2, *Asperula stylosa*; 3, *Anchusa italica*; 4, *Eschscholtzia californica*; 5, *Geranium sanguineum*; 6, *Muscari comosum*.—*Fresco.* 1, *Veronica spicata*; 2, *Saxifraga species*; 3, *Helianthemum vulgare*; 4, *Sedum species*; 5, *Thalictrum adiantifolium*; 6, *Saxifraga hypnoides*.—*C. B. L. S.* *Paulownia imperialis*; it is common in gardens in favourable localities; but is not planted so extensively as formerly.

PEACHES DROPPING: R. M. There is no fungus present; the dropping is due to some cultural defect, probably improper watering of the border during the resting season.

PEAR LEAVES INJURED: E. M. C. and G. W. R. The injury has been caused by the Pear-leaf blister-mite. Spray the trees thoroughly with paraffin emulsion prepared by boiling together equal proportions of paraffin and soft soap. This should be thoroughly mixed with 25 times its bulk of water. Spray in the autumn and again in the early spring when the leaf buds are expanding.

PRESERVING SPECIMENS OF CONIFEROUS TREES: H. A. W. There is no satisfactory way of preventing Conifer "needles" from becoming detached. The best plan is to lightly touch the under surface with a film of seccotine, but it is impossible to secure them all. The loose ones may be kept in an envelope attached to the page. The season of the year for gathering the specimens, and the dipping of the specimens into boiling water, have been the subjects of experiment, but with no success. We have sometimes stitched the needles down to the paper in their places with dark cotton, but this was a tedious process, and, after all, they soon became detached from the stem.

RAINFALL: A. J. You will receive this information from the Meteorological Office, 63, Victoria Street, London, S.W. The records of the rainfall at Chiswick for a period of 60 years is published in the Royal Horticultural Society's *Journal*.

ROSE RUST: B. M. & Sons. The Orange-coloured appearance of the shoots is due to the presence of a fungus, *Phragmidium subcorticatum*. The appearance of the disease in spring depends on the presence of resting spores from the previous autumn. It is, therefore, necessary to collect and burn all fallen leaves in the autumn. Spraying with diluted Bordeaux mixture or ammoniated carbonate of copper solution will check the spread of the disease. The fungus also grows on wild Roses, and these may become a source of infection unless proper precautions are taken.

STRAWBERRY FLAVOURING: F. R. A. We have no knowledge of any special variety used for flavouring ice-cream.

TULIPS DISEASED: Miss G. and A. R. The mould on the leaves—*Botrytis cinerea*—is a dangerous pest, and has been favoured by the wet weather. The soil in which the bulbs were planted should be given a dressing of gas lime, otherwise the infection will spread. Seed produced by plants of the diseased Forget-me-Nots should not be kept.

WILLOW DISEASED: Windermere. The injury is due to a well-known fungus—*Phyalospora salicis*. The only remedy is to remove and burn as much as possible of the injured parts to prevent further infection.

THE CONSTRUCTION OF DRIVES AND PATHS.

THE object of a drive or path is to provide easy access to the main features of interest in its locality, and in such a manner as to enable them to be viewed to the best advantage.

Before deciding upon the course of a drive, it is well to go very thoroughly over the ground, not only with a view of mapping out the most attractive direction, but also the most convenient gradient, which should be as uniform as possible, and in no case exceed a fall of one foot in eight. Straight lines should, generally speaking, be avoided, and in their place a succession of long, sweeping curves should be made, which will present, as one proceeds, an ever-varying change of scenery. It may lead, we will suppose, from the vicinity of a dwelling-house through the open park or garden into an adjoining wood, emerging from under the shade of lofty forest trees to an open glade, upon which Primroses, Bluebells, and other native wild flowers vie with each other for supremacy; next, turning a corner and following, through a plantation of Willows or Alders, the course of a babbling brook, afterwards ascending

through a cutting of heather-clad rocks, and so on.

Should the required drive lead to the top of a steep hill, it will sometimes be advisable to assume a zig-zag course, and consequently turn rather abruptly at the corners; ample provision must be made for turning these corners safely, and it is well to err on the safe side as regards allowing sufficient space.

The course to be taken should be accurately mapped out by means of wooden pegs driven firmly into the ground at convenient intervals. The work of construction will have to be carried out according to circumstances and the kind of drive or path desired. The heavier the traffic is expected to be, the more solid must the drive be constructed.

In the formation of either drives or walks, it is usually best to make up the sides first, so as to obtain a good line, and if the gradient can be so arranged that the soil from the cuttings can be made sufficient for all filling that may be required in other parts, so much the better.

One of the most delightful, and at the same time most natural, means of access is the grass-covered path, which enables one to get within easy reach of subjects of individual interest, such as a group of flowering shrubs, or a particular tree, or some choice specimen on the rock-garden; also for woodland purposes a grass vista is often very desirable. Provided the ground is fairly even, and the woods not too dense to admit a certain amount of sunshine, a grass-covered walk can be formed with very little trouble, either by levelling the surface of the existing grass and adding a little additional turf where necessary, or by sowing seeds of a suitable mixture of woodland grasses along the track after it has been brought to the required level. One of the greatest attractions of a grass-covered path is, as before mentioned, its natural appearance, and the ease with which its surroundings can be beautified by means of wild flowers, naturalised bulbs, &c.

Such a path may vary in width from 5 to 20 feet, according to the space available; 20 feet wide it might also be used for occasional light traffic and sporting purposes. The ground should be well drained, and if the soil is very retentive, additional drainage should be provided by forming a small ditch along each side of the walk.

If a drive has to be made which will form an approach to the dwelling-house, it must be so constructed as to effectually withstand all kinds of traffic without injury, and allowance must be made in excavating, for the spreading of 8 to 12 inches of hard, porous material over the surface of the drive.

Upon the completion of the necessary excavations, provision must be made for suitable drainage. In some cases it will suffice to turn the surface water on to the adjoining land by means of outlet channels. This, however, is not always possible or desirable, in which case a drain of 3 or 4-inch pipes should be run along the course of the drive, either in the centre, which is preferable, or at the side. The pipes should be laid at about 3 feet deep, and be filled over with rubble, in order to conduct the water. So-called gully-holes, consisting of square holes built in brick, and fitted at the top with an iron grid, should be constructed at intervals along the side of the

drive for the purpose of conducting the surface water into the drain. On perfectly level ground or steep places these gully holes should not be more than 25 yards apart, but on an easy gradient a distance of 50 yards apart will suffice.

Outlet pipes from gully holes should be fixed in such a manner as to allow a few inches at the bottom for the accumulation of refuse, and thereby allow of its being cleared out occasionally. If it is desired that the approach should admit of two carriages passing each other conveniently, it should not be less than 15 feet in width. The stone or other material used for strengthening the road should be laid on in such a manner as to be 2 or 3 inches higher in the middle than at the sides.

The ordinary drive, by which is understood a drive for light traffic only, especially if it is to traverse uneven ground in hilly districts, should also be provided with a suitable depth of strengthening material, but 6 to 9 inches will be sufficient. The drainage in this case can either be conducted on to the adjoining land or provided for by means of gullies, as circumstances permit. The width of an ordinary drive should not be less than 8 feet or more than 14 feet. If the drive is to be carried along the side of a steep slope, I have found it a good plan to bank up the soil obtained during the excavation on to the lower side, and to secure it by means of a wattled fence buried in such a manner as to be hidden from view as far as possible; these fences, if well constructed, will last a number of years, by the end of which time the banked-up soil will have become sufficiently self-supporting. A drive of this kind is very useful for the purpose of making a circular tour round the premises, and should be provided with one or more main branches, in order to secure a near "cut" from one side of the grounds to the other. The walk or pathway should serve the purpose of connecting up different parts of the drive or drives, and may vary in width from 4 to 10 feet, and may be surfaced with grass, moss, gravel, or some other porous material.

The advantages of a grass covered path have already been referred to, but where the soil is poor and the ground uneven, a gravel path is preferable, and has the advantage, if well made, of being dry to walk upon all the year round. A few inches of rough, moderately-solid material may be used with advantages as a foundation for the gravel to work into. By means of a path, access should be possible to such features of interest as cannot easily be reached, on account of the gradient or other reasons, by the drive, and as such a path can easily be furnished with steps, the question of gradient need not be taken into consideration.

Having completed the necessary preparatory work according to the requirements, there arises the question of the most suitable material for strengthening purposes. The best material to be used will depend on circumstances, and a good selection may be made from among the following:—Basalt stone, granite, limestone, shingle, cinders, bricks, builders' refuse, and clay. Except where the proposed drive is to stand the wear and tear of heavy and constant traffic, it is generally best to make use of such of the materials mentioned as are most easily obtainable in the district. It often happens, especially in hilly districts, that suitable stone can be found within easy carting distance upon the estate, or even be procured from the excavated material of the drive itself. P. M.

(To be continued.)

BOTANICAL WORKS OF THE LATE DR. MASTERS.

(Continued from page 378.)

It has been mentioned that Dr. Masters had many special studies, among which vegetable teratology held the foremost place for many years. In Taxonomy he was an acknowledged authority on the orders Coniferæ, Restiaceæ, Aristolochiaceæ, and Passifloraceæ. Excluding the contributions on the Coniferæ which appeared in the *Gardeners' Chronicle*, his writings on this order are more numerous and more comprehensive than on any other, and appeal equally to the botanist and horticulturist. The principal papers are in the *Journal of the Linnean Society*, beginning with: "Notes on the Relations between the Morphology and Physiology in the Leaves of Certain Conifers," 1880, vol. xvii., pp. 547-552, and followed by II., "The Conifers of Japan," 1881, vol. xviii., pp. 473-524, tt. 19 and 20, and many figures in the text. III., "Contributions to the History of Certain Species of Conifers," 1886, vol. xxii., pp. 169-212, tt. 2-10, and numerous figures in the text. IV., "Review of some Points in the Comparative Morphology, Anatomy, and Life-History of the Coniferæ," 1890, vol. xxvii., pp. 226-332, with 29 figures in the text. V., "Notes on the Genera of Taxaceæ and Coniferæ," 1893, vol. xxx., pp. 1-42. VI., "A General View of the Genus Cupressus," 1896, vol. xxxi., pp. 312-363, with numerous figures in the text. VII., "Coniferæ of China," in Forbes' and Hemsley's "Enumeration of the Plants of China," 1902, vol. xxvi., pp. 540-559. VIII., "A General View of the Genus Pinus," 1904, vol. xxxv., pp. 560-659, tt. 20-23. IX., "On the Conifers of China," 1906, vol. xxxvii., pp. 410-424. Masters also took the leading part at the Conifer Conference of the Royal Horticultural Society in 1892, and delivered the opening address, the theme of which is, "Some Features of Interest in the Order of Conifers." He also contributed a "List of Conifers and Taxads in Cultivation in the Open Air in Great Britain and Ireland." This is really much more than a list, containing, as it does, historical, bibliographical, and descriptive information, and a copious synonymy of the genera and species. It appeared in the Society's *Journal*, 1892, N.S., vol. xiv., pp. 179-256, and it was also issued separately. There are some smaller contributions on Conifers, such as: "De Coniferis quibusdam sinicis vel japonicis Adnotationes quaedam," in *Bulletin de l'Herbier Boissier*, 1898, vol. vi., pp. 269-274. II., "Taxodium and Glyptostrobus," in *Journal of Botany*, 1900, vol. xxxviii., pp. 37-40. III., "Chinese Conifers Collected by E. H. Wilson," in *Journal of Botany*, 1903, vol. xli., pp. 267-270. Finally, the first paper on the list for reading at the meeting of the Linnean Society on Thursday last, June 20, was one by the late Dr. Masters, "On the Distribution of Conifers in China and Neighbouring Countries."

The foregoing list does not pretend to be a complete bibliography of Dr. Masters' contributions to the literature of the Coniferæ; but it includes all the papers to which I have references at hand as likely to be useful. One exception deserves to be made with regard to the *Gardeners' Chronicle*, namely, "Description of West American Conifers," 1880, vol. xiii., p. 648; 1880, vol. xiv., p. 720; 1881, vol. xv., pp. 179, 236, 660; 1883, vol. xix., p. 45. I had almost forgotten the fact that Masters was a contributor to the great *Pinetum Britannicum*.

Passing to the elegant and curiously-constructed Passifloraceæ, the most important work is the monograph of the South American species in the *Flora Brasiliensis*, 1872, vol. xiii., pp. 529-628, tt. 106-128. In this monograph, *Tacsonia* is treated as a genus, and 25 species are

described; all Andine, or, at least, western; none Brazilian. Of *Passiflora* itself, 175 species are described, nearly half of which are Brazilian. Since that date many new species have been discovered in South America, most of which were described by Masters himself. There is also the new genus, *Mitostemma*, Masters, of two species; one from British Guiana, the other from Brazil.

No one knew better than Masters that there were connecting links between typical *Passiflora* and typical *Tacsonia*, but he preferred retaining them as separate genera to the end. On this point he makes the following observation under *Tacsonia*: "Genus sat naturale cum *Passiflora* ab auctoribus pluribus conjunctum, differt ab illa florum forma, coronæ dispositione nec non distributione geographica specierum. Species intermediæ, quæ a Candolleo in *Tac-*

FIG. 165.—CLUMP OF GLADIOLUS "THE BRIDE":
FLOWERS WHITE.

soniæ sectiones *Distephana* et *Psilanthus* disponuntur, mihi rectius ad *Passifloras* veras pertinere videntur."

Since the foregoing was written, further connecting links have been discovered, yet it seems more convenient for practical purposes to keep up both. *Passiflora fuchsiiflora* (Hooker's *Icones Plantarum*, t. 2553) again, is a *Dilkea* in structure, except that it has only three style-arms instead of four.

In regard to the distribution of *Passiflora*, Masters remarks that no indigenous species had been found in Africa, and recent explorations in all directions have not yielded one, though several very curious new genera of the order *Passifloraceæ* have been discovered in that country. Only two species were known to inhabit India, and the number has not been increased, but, including unpublished ones, six new species have been found in Western China.

Unfortunately, the colossal *Flora Brasiliensis* is accessible to comparatively few persons, but Masters published the results of his studies and researches in various places. His "Contributions to the Natural History of the Passifloraceæ" (*Transactions of the Linnean Society*, 1871, vol. xxvii., pp. 593-646, tt. 64 and 65) are very comprehensive and highly interesting, treating, among other things, of the organography, development of the various organs, teratology, anatomy, fertilisation, and germination of the order. The beautiful and often complex coronal structures are described in detail. Under the head of corona is included all that series of rings, scales, or threads intervening between the petals and the stamens. From their almost universal presence in the species of the order, their variety of form, and the parts they play in the physiological functions of the flower, considerable interest attaches to them. The corona is met with in its greatest complexity in some species of *Passiflora*, and in its greatest simplicity in the genera *Malesherbia* and *Gynopleura*. In the latter it exists only as a thickened rim or a series of tubercles projecting from the margin of the floral-tube, whereas in some species of *Passiflora*, such as *P. quadrangularis*, it is exceedingly complex. Masters describes the different series from above downwards. I., perfect rays, consisting of two or three rows, of distinct threads. II., imperfect rays, consisting of a variable number of short and, as it were, imperfect or rudimentary threads. III., a membranous ring, the "false operculum" found in *P. quadrangularis* and in one or two other species only. IV., a membranous sheath called the "operculum," which shuts off the nectary proper from the upper part of the flower-tube. Below this there is, in some species, a thickened rim projecting from the side of the nectary and partially dividing it into two compartments, an upper and a lower. Lastly, there is sometimes a shallow membrane or thickened cup at the base of the gynophore.

In this connection we might extract from the paragraphs on fertilisation did space permit; but, passing over many minor papers, chiefly descriptions of new species, we come to the useful "Classified Synonymic List of all the Species of *Passifloraceæ* Cultivated in European gardens, with references to the works in which they are figured." This appeared in the *Journal of the Royal Horticultural Society*, 1874, vol. iv., pp. 125-148, tt. 6-8, and a new edition brought up to date is very desirable.

(To be continued.)

GLADIOLUS "THE BRIDE."

The pure white variety of *Gladiolus Colvillei* is by far the most hardy of all the early Gladioli, and may be grown in a light, well-drained soil without difficulty. A spot which is exposed to full sunshine on a south terrace suits this plant perfectly, and a few bulbs, planted in such a position in August, will quickly increase, forming a handsome group after the lapse of a year or two. The flowers open in June. Bulbs grown in this way for three years should then be taken up after the foliage has died away in summer. The finest of the bulbs can be selected for forcing if desired, replanting the others in a fresh position without delay. They succeed best when not removed from the soil for any length of time, as they naturally start into growth early in the autumn. A mulch of well-decayed manure should be laid over them in March every year, and in cold districts it may be desirable to cover them with a conical pile of fine coal-ashes during the winter; but they do not appear to suffer from frost when cultivated in a well-drained position. L. L. R.

ORCHID NOTES AND GLEANINGS.

ODONTOGLOSSUM NOBILE
(PESCATOREI).

ODONTOGLOSSUM nobile, although it is not equal to the varieties of *O. crispum*, is very beautiful when properly grown, and might well

few purple spots have developed on the sepals and petals, one having them very quaintly arranged along the mid-ribs of the segments towards the tips. It is said that in some gardens *O. nobile* is a shy flowerer, but here, although the plants are rather small, most of them are in bloom and are very effectively arranged with the

flowers represent one, is sent by F. Menteith Ogilvie, Esq., The Shrubbery, Oxford (gr. Mr. Balmforth). There are five segments of the nature of sepals, and one which is part sepal and part petal, the other three petals being perfect. There are two labellums diverging right and left, and two columns joined from the ovary to near the apex. All the parts are regularly displayed, and the colour is primrose-yellow spotted with reddish-brown, the sepals having the larger spots and the petals the smaller, together with a thin reddish line at the base, and which can be traced in the part of a petal which is joined to a sepal.

EPIDENDRUM (NANODES) MEDUSÆ.

A VERY fine specimen of this extraordinary species is in bloom in the gardens of Malcolm S. Cooke, Esq., Tankerville, Kingston Hill (gr. Mr. Buckle), where it is considered one of the most attractive of cool house Orchids. The long fleshy stems, furnished with two rows of greyish-green leaves, are pendulous, and bear at their extremities one or two flowers of thick substance, the showy portion of which is the orbicular, deeply-fringed, claret-purple labellum, which measures from 2 to 3 inches across. With its drooping growths furnished with a good number of these very remarkable flowers, the specimen is a fine object. It was described as *Nanodes Medusæ* by Reichenbach in the *Gardeners' Chronicle*, 1887, p. 432, and was figured in the *Botanical Magazine*, t. 5723.

EPIDENDRUM (NANODES)
MATTHEWSII

is also in cultivation. It is of dwarf tufted habit and bears pretty ruby-purple tinted flowers. Both species remain for a long time in flower. The *Nanodes* should be grown in baskets or Orchid pans, and suspended in the *Odontoglossum* house or the coolest part of the *Cattleya* house.

DENDROBIUM THYRSIFLORUM
GALLICEANUM.

A PHOTOGRAPH of an ally of this singular variety, which was figured in *Lindena*, VI., t. 241, is sent by Mr. R. Robinson, Roath Park, Cardiff, who also sent an inflorescence to the Temple Show, but which arrived in a withered condition. The photograph shows a fine plant with three spikes, and the flowers have the sepals and petals as in typical *D. thyrseiflorum*, but the labellums by an abnormal development which is in this plant, as in the original *D. t. Galliceanum*, a fixed character, are narrowed, elongated, not cupped, the colour being whitish tinged with yellow. It is a very singular and pretty variety.

POLYGONUM BALDSCHU-
ANICUM.

THIS hardy, perennial-climbing plant, introduced from Bokhara, is now better known in gardens than in 1897, when we reproduced a photograph kindly sent us by M. V. Lemoine, of Nancy. At the same time, from numerous enquiries we receive respecting this species, it is evident that there are many gardeners who have not cultivated it, and therefore the illustration at fig. 166 may serve to show what a charming species it is for training over tree stumps, pillars, fences, or pergolas. The plants are now approaching the flowering period, and they will continue in bloom until the end of summer. *Polygonum Baldschuanicum*, like most of the other species, succeeds in ordinary garden soil, but this should be well enriched with manure, in order that the plants may be able to make long and stout growths, capable of flowering profusely as shown in the illustration. The flowers have been described as pink, and white on various occasions, owing partly to slight variability in the plants, and to the different conditions in which they are cultivated. If the plants are introduced to artificial heat it has the effect of destroying the pink colour.

[Photo by F. Mason Good.]

FIG. 166.—POLYGONUM BALDSCHUANICUM: HARDY PERENNIAL CLIMBER; FLOWERS PINK.

claim the second place as an attractive, white-flowered species. A very nice batch of plants is in flower in the Orchid nursery of Mr. H. A. Tracy, Amyand Park Road, Twickenham, showing great variety in the flowers. One has pure white flowers with an orange crest to the lip; some have unusually large labellums decorated with dark violet blotches; and in several a

larger-flowered *O. crispums* and other species, together with several very handsome hybrid *Odontoglossums*.

ODONTOGLOSSUM ANDERSONIANUM.

AN extremely beautiful example of abnormal characters in the flowers of *Odontoglossum Andersonianum*, in which the parts of two

REPORT ON THE RESULTS OBTAINED FROM THE SUMMER PRUNING OF FRUIT TREES.

[FROM OUR OWN CORRESPONDENTS.]

DATE CONSIDERED BEST TO COMMENCE SUMMER PRUNING OF APPLE, PEAR, AND PLUM TREES, &c.	GENERAL RESULTS FROM SUMMER PRUNING.	NATURE OF SOIL.	NAME AND ADDRESS.
SCOTLAND:			
0, Scotland, N.			
Apples and Pears, July 15	Good	Heavy loam on stiff subsoil of clay	T. MacDonald, Balfour Castle Gardens.
Beginning of July	Indifferent	Heavy loam on clay	J. McIvor, Skibo Castle Gardens, Dornoch.
1, Scotland, E.			
Plums, first of July; Pears, middle of July; Apples, end of July	Indifferent	Medium, shallow loam on hard pan subsoil	J. Grant, Rothienorman Gardens.
End of June	Fairly satisfactory	Heavy soil on clay	J. Brown, Delgaty Castle Gardens.
Second or third week in August		Deep black soil with many stones on a subsoil of sand and stones	G. Edwards, Ballindalloch Castle Gardens.
If growth is vigorous, in June and July; if moderate, in August	Good	Good loam on clay	A. Blackwood, Academy Gardens, Doilar.
End of July	Beneficial; Apples are not treated.	Red loam on sand	W. Henderson, Balbirnie Gardens.
Middle of August	Valuable only in the case of wall trees and espaliers	Light soil deficient in loam; subsoil gravel	F. McRobbie, Tarvit Gardens.
Pears, Plums and other stone fruits, June 26 to July 15	Increased fruitfulness of trees		R. P. Brotherston, Tynninghame Gardens.
Third week in July	Good	Light loam on sand	C. Simpson, Wemyss Castle Gardens.
Middle of July, commencing with Cherries and Plums	Most satisfactory.	Along coast, sandy on gravel; inland, heavy loam on clay	T. Wilson, Glamis Castle Gardens.
Apples, Pears, Apricots, and Sweet Cherries on walls as soon as the fruits are set, and again later. Standard Peaches, Nectarines, and Morello Cherries, August 1 to 10.		Sandy loam on almost pure sand	W. Alison, Seaview Gardens.
Middle of July to Middle of August, according to season	Good	Light soil on gravel subsoil	W. Galloway, Gosford Gardens.
First to third week in July	Good	Sandy loam on gravel	J. M. Brown, Blackhall Castle Gardens.
Apple and Pears, middle of July; Plums, Apricots, &c., at the end of July	Good	Stiff sandy clay on rock	W. Knight, Fasque Gardens.
Plums, the middle of June; Apples and Pears, July 1 to 15	Good	Light sand on gravel	W. Pirie, Dalhousie Castle Gardens.
The first week in August	Good	Red loam on red clay	J. Whytock, Dalkeith Gardens.
Stone fruits, middle of July; Apples and Pears, the first week in August	Good	Heavy loam on clay	W. McDonald, Cardrona Gardens.
About the last week of June	Fairly good	Light loam on gravel	J. Farquharson, Kinfauns Castle Gardens.
			J. Robb, Catherinesbank.
6, Scotland, W.			
Pears and Plums, early in July; Apples, about mid-summer; Sweet Cherries, when growths have made about five inter-nodes.	Good	Sandy loam on pure sand; part of orchard sandy peat	D. S. Melville, Poltalloch Gardens.
Stone fruits, third week in July; Apples and Pears, first week in August	Good	Solid rock 6 to 18 inches below the surface	H. Scott, Torloisk Gardens, Aros.
About July 15	Indifferent	Heavy loam on clay	W. Priest, Eglington Gardens, Kilwinning.
Middle to end of July	Good	Good loam on gravel	D. Buchanan, Bargany Gardens.
Last week in June or first in July	Good	Light on sandy subsoil	T. Gordon, Ewenfield Gardens.
Apples and Pears, beginning of July; Plums and other stone fruits, middle of June.	Good	Shallow and cold on rocky base	D. Stewart, Knockderry Castle Gardens.
Last week in June	Induces the formation of flower buds	Clay-loam on heavy clay	J. Urquhart, Hoddon Castle Gardens.
Beginning of August	If performed earlier the results are bad	Loam, on sand and gravel	J. MacDonald, Dryfeholm Gardens, Lockerbie.
Apples and Pears, end of July; stone fruits, second week in July	Good	Shallow, on a gravel bottom	N. Macfadyen, Glenlee Park Gardens, New Galloway.
Last week in July and the first in August	Good	Light, sandy loam on clay	A. Marshall, Ballikrain Castle Gardens.
Middle of August	Good	Stiff loam on clay	J. Miller, Castlemilk Gardens.
In June	Indifferent	Sandy on a gravel subsoil	T. Lunt, Ardgowan Gardens.
First week in August	Good	Loam on gravel	J. Bryden, Dunragit Gardens.
Last ten days of July; cordon trees earlier	Satisfactory	Good loam on gravel and sand	J. Day, Galloway House Gardens, Garlieston.
ENGLAND:			
2, England, N.E.			
DURHAM.			
From July 12 to 20	Indifferent	Limestone	R. Draper, Seaham Hall Gardens.
In July	Good (in the case of wall trees)	Strong loam on clay	J. Noble, Woodburn Gardens.
	Good	Black, heavy soil on cold, heavy clay	J. Machar, Smelt House Gardens.
YORKSHIRE.			
Apples and Pears, middle of July	Indifferent; crops always less	Moderately good loam on Yorkshire grit	J. Simpson, Studfield.
Plums, first week in July	Good	Strong loam over clay resting on chalk	John Allsop, Dalton Hall Gardens.
Strong-growing Apples and Pears, second week in July; weaker kinds, ten days earlier; Apricots and Plums on walls, first week in July.	Fairly good	Stiff loam on magnesium limestone	Henry J. Clayton.
Middle of July	Good (in the case of wall trees)	Light loam on sand or stones	John McClelland, Ribston Hall Gardens.
3, England, E.			
CAMBRIDGESHIRE.			
Apples and Pears, August 1; Plums and other stone fruits, July 18 ..	Good	Light and open on gravel and chalk	R. Alderman, Babraham Hall Gardens.
ESSEX.			
Commence with Pears, middle of June, following with Plums and Apples	Good	Stiff loam	Arthur Bullock, Copped Hall Gardens, Epping.
Middle of July	Good	Loam on clay	Henry Lister, Easton Lodge Gardens, Drumow.
Middle of July	Aids the formation and the plumping of fruit buds, and assists in securing symmetrical trees	Loam on clay	H. W. Ward, Lime House, Rayleigh.
Second week in July	Good	Light, sandy soil on gravel	W. R. Johnson, Stanway Hall Gardens.
LINCOLNSHIRE.			
Stone fruits, last week in June; Pears, first week in July; Apples, second week	Good	Brown loam, on blue clay or ironstone	H. Vinden, Harlaxton Manor Gardens.
End of June to middle of July	Good, if growths are not shortened too severely	Strong loam on clay	F. J. Fleming, Weelsby Old Hall.
NORFOLK.			
Pears, second week in July; Apples, third week	Indifferent	Mostly sandy, on chalk or gravel	E. O. Parlow, Shadwell Court Gardens.
First week in July	Good	Mixed soil on gravel	J. W. Bradhook, Ketteringham Park Gardens.
August	Indifferent; no effect on cropping	Light	W. N. Thurston, Witton Park Gardens.
SUFFOLK.			
Second week in July, commencing with Cherries, and following with Plums, Pears, and Apples; Apples, end of July or beginning of August.	Good, if not performed too early		Thos. Simpson, Henham Hall Gardens.
Apples, last week in July; Pears and Plums, first week in August	Good	Mixed soil on sand	A. Hickford, Darsham House Gardens.

RESULTS OBTAINED FROM THE SUMMER PRUNING OF FRUIT TREES—(continued).

DATE CONSIDERED BEST TO COMMENCE SUMMER PRUNING OF APPLE, PEAR, AND PLUM TREES, &c.	GENERAL RESULTS FROM SUMMER PRUNING.	NATURE OF SOIL.	NAME AND ADDRESS.
4, Midland Counties.			
BEDFORDSHIRE.			
Apples and Pears, second week in July; stone fruits, June 19	Indifferent	Gaulty clay	H. Nimmo, Cranfield Court Gardens.
Apples, Pears, Plums, and Cherries, from the latter part of June to end of July.	Indifferent	Very strong loam on clay	T. W. Birkinshaw, Hatley Park Gardens.
Never before the fruits are gathered, unless the trees have failed to bear.	Indifferent, owing to poor quality of soil	Sand, loam and gravel	H. W. Nutt, Flitwick Gardens.
Pruning is regulated by the season	Good	Sandy loam, chalk and clay	George Mackinlay, Wrest Park Gardens.
End of June	Very indifferent	Sand, on stiff, blue clay	Wm. F. Palmer, Fozzfield Gardens.
Pears, Plums, and other stone fruits, second week in June; Apples, third week in June.	Good	Sandy loam on sand	O. J. Ellett, Chicksands Priory Gardens.
BUCKINGHAMSHIRE.			
Early in July	Good	Gravelly	John Fleming, Wexham Park Gardens.
Apples and Pears, second week in July; Plums, end of July	Good, if root-pruning is practised in addition	Heavy loam on brick-earth	Chas. Page, Dropmore Gardens.
End of August and early September	Fairly good	Heavy loam on clay	W. Hedley Warren, Aston Clinton Gardens.
July 20	Good	Heavy clay	James MacGregor, Mentmore Gardens.
CHESHIRE.			
Middle of July	Very good	Light, sandy loam on a clayey bottom	Geo. W. Lilley, Moreton Hall Gardens.
Apples and Pears, last week in July; Plums, middle of July	Good	Light and open on a boggy subsoil	Peter Wilkinson, Walton Lea Gardens.
DERBYSHIRE.			
Plums, early in July; Apples and Pears, middle of July	Indifferent, but conduces to neatness, and, in Plums, destroys many aphides	Heavy on clay	J. C. Tallack, Shipley Hall Gardens.
June 20	Good	Friable loam on clay	T. Keetley, Darley Abbey Gardens.
Apples, not earlier than July 10; Pears and Plums, about July 20	Very indifferent	Close, retentive, and cold on clay	F. G. Mills, Glossop Hall Gardens.
Apples, July 10; Pears and Plums, July 20	Very indifferent	Retentive and cold, with an absence of lime; subsoil clay	F. G. Mills, Lonsdale Home Farm, Glossop.
Older Pear trees on walls, end of June; Apricots and pyramid Apple trees, in July.	Good	Medium to heavy texture; subsoil gravel	J. Tulley, Osmaston Manor Gardens.
HERTFORDSHIRE.			
Apples and Plums, end of July; Pears, early in August; Cherries, when fruits commence to colour.	Trees flower freely	Strong loam on layer of clay, resting on sand	O. R. Fielder, North Mymms Park.
Pears, July 14; continuing with Apples, Plums, &c.	Satisfactory	Good loam on gravel	C. E. Martin, The Hoo Gardens.
Apples, not summer pruned; Pears, first week in July	Good	Light loam on gravel	H. Prime, Hatfield House Gardens.
First week in July	Satisfactory	Strong clay	F. W. Gooch, Edge Grove Gardens.
Apples and Pears, July 20; Stone fruits, July 15	Satisfactory	Loam with gravel and chalk as subsoil	E. Beckett, Aldenham House Gardens.
Middle to end of August	Good	Gravelly	W. Whitelaw, Batchwood Gardens.
Second week in July	Good	Loam on subsoil of red clay	H. Parr, Trent Park Gardens.
LEICESTERSHIRE.			
Peach trees, middle to end of June; following with Plums, Pears, and Apples in order named.	Good	Stiff clay on the lias formation	D. Roberts, Prestwold Hall Gardens.
Pears and Plums, middle of June, taking the younger trees first; Apples, Cherries, and Apricots, middle of July; Peaches and Nectarines throughout the growing season.	Good		W. H. Divers, Belvoir Castle Gardens.
NORTHAMPTONSHIRE.			
End of July	Indifferent	Heavy loam on clay	R. Johnston, Wakefield Lodge Gardens.
From July 20 to middle of August	Good	Ironstone	H. Turner, Fineshade Abbey Gardens.
Last week in July	Good	Gravelly loam on gravel	A. Farr, Holme Pierrepont Hall Gardens.
NOTTINGHAMSHIRE.			
Apples, July 25; Pears and Plums, July 30; other stone fruits, August 5.	Good	Clay	James Gibson, Welbeck Abbey Gardens.
Apples, Pears, and Plums, from middle to the end of July.	Good	Light loam on gravel and chalk	J. A. Hall, Shiplake Court Gardens.
After the middle of July	Good	Very strong loam, on gravel or clay	A. J. Long, Wyfold Court Gardens, Reading.
OXFORDSHIRE.			
Completed at end of July	Good	Heavy loam on clay	J. Broadfoot, Shotover Gardens, Wheatley.
First week in July	Good on dwarf trees	Sandy loam on gravelly subsoil	A. S. Kemp, Broadway, Shifnal.
SHROPSHIRE.			
About second week in July	Fairly good	Strong clay on limestone formation	J. Loudon, The Quinta, Chirk.
End of June	Good	Light, on gravelly subsoil	C. Robinson, Pitchford Hall Gardens.
Beginning of July	Usually good	Heavy, on a marly subsoil	T. Bannerman, Blithfield Gardens.
STAFFORDSHIRE.			
Finished in July	Good	Stiff loam on water clay	G. Woodgate, Rolleston Hall Gardens.
WARWICKSHIRE.			
Summer pruning not much practised; unnecessary	Admits air and light, otherwise of little use	Light loam resting on red clay	W. Miller, Berkswell.
Apples, July; Pears, September; Plums and other stone fruits, from July to August.		Heavy clay to gravel	T. Masters, Estate Office, Shuckburgh.
5, Southern Counties.			
BERKSHIRE.			
Pears, July; Plums and other stone fruits, end of June; Apples, early in August.	Good	Stony on gravel	G. Cooper, Oakley Court Gardens.
Wall trees, middle of June; bush trees, middle of July	Good	Light, resting on gravel	J. Howard, Benham Park Gardens.
Middle of July	Good	Chalky loam on rock subsoil	W. Fyfe, Lockinge Gardens.
No summer pruning of standard trees of Apple and Pear; wall trees pruned middle of July.	Satisfactory	Gravel on clay	J. Coombes, Englefield Gardens.
Cherries and Plums, at beginning of July; Pears and Apples afterwards	Good	Retentive, on stiff clay	W. Pope, Highclere Gardens.
DORSETSHIRE.			
Early in August, excluding weak-growing varieties	Good	Sandy nature on chalk	H. Birkinshaw, Chedington Court Gardens.
Stone fruits, beginning of July; Apples and Pears next, excluding bush and pyramid-trained trees.	Advantageous	Heavy loam on rocky subsoil	T. Turton, Castle Gardens.
June 24 to middle of July; Apples, Pears, and Plums in rotation	Causes trees to flower freely; better than winter pruning for Plums and Apricots	Light texture on chalk	T. Denny, Down House Gardens.
Apricots and Cherries, end of June, continuing with Plums, Pears, and Apples.	One operation answers well	Light loam and vegetable mould on loose, sandy gravel	B. Campbell, Kingston House Gardens.
HAMPSHIRE.			
Midsummer	Good	Heavy clay	A. Lee, Palace House Gardens.
Pears, Plums, and Cherries, middle of July; Apples afterwards	Good	Heavy and retentive, on clay which overlies chalk	E. Molyneux, Swanmore Park.
Plums, beginning of July; Pears next, and Apples afterwards	Aids maturation of wood. Induces formation of fruit buds.	Clayey loam on London clay	A. G. Nichols, Strathfieldsaye Gardens.
Pears and Plums, end of June; Apples in August	Good	Light, resting on gravelly clay	J. Wasley, Sherfield Manor Gardens.
KENT.			
End of July	Good. Aids ripening of remaining buds	Sandy loam, resting on sand	H. J. Knight, Preston Hall Gardens.
Apples and Pears on Paradise and Quince stocks, middle of July; Plums, July and August.	Very good	Stiff, with a subsoil of pin-nick. This latter is like clay, and contains many stones.	G. Woodward, Barham Court Gardens.
August 1	Most beneficial	Sandy loam on Kentish ragstone	Geo. Bunyard, Maidstone.
July 10	Good	Light, resting on the Kentian ragstone	W. Lewis, East Sutton Park Gardens.
Cherries, Plums, &c., middle of June; Pears and Apples, early in July	Satisfactory	Loam on Kentish ragstone	G. Fennell, Bowden.
Apples and Pears, July 25 to August 1; Plums are not summer-pruned	Good		B. Champion, Mereworth.

RESULTS OBTAINED FROM THE SUMMER PRUNING OF FRUIT TREES—(continued).

DATE CONSIDERED BEST TO COMMENCE SUMMER PRUNING OF APPLE, PEAR, AND PLUM TREES, &c.	GENERAL RESULTS FROM SUMMER PRUNING.	NATURE OF SOIL.	NAME AND ADDRESS.
5, Southern Counties.			
KENT (continued).			
Apples, end of June and middle of August; Pears, middle of July; Plums, &c., end of July.	Indifferent here, except on young trees. Other districts beneficial	Light loam to gravel on a "pan"	W. Humphreys, Blendon Hall Gardens
First and second weeks in July	Good	Heavy loam on a brick-earth	W. Dixon, Old House Gardens, Walmer.
MIDDLESEX.			
Apples and Pears, after middle of July; stone fruits, much earlier; Peaches, as soon as fruits are removed.	Good	Light in texture, resting on gravel	G. Wythes (late), Syon House Gardens.
Any time during July	Good	Shallow and sandy, resting on gravel	H. Markham, Wrotham Park Gardens.
Apricots and Sweet Cherries, Pears, Plums, and Apples on walls, first or second week in June; second growth pinched to second or third leaf, middle of August.	Good	Loam, resting on clay	W. Watson, Harefield Place Gardens.
Apples and Pears, in July; Plums, &c., in November	Good	Loam, resting on gravel	W. Bates, Cross Deep Gardens.
Apples, first week in July; Pears and Plums, end of June	Very good	Light loam on gravel subsoil	J. Hawkes, Osterley Park Gardens.
SURREY.			
July	Good	Chalk and flints	W. Bain, Burford Gardens, Dorking.
End of July or early in August	Very good	Sandy, on sandy subsoil	S. T. Wright, Royal Horticultural Society's Gardens, Wisley.
Middle of July	Far better left alone, unless performed by a very skilful and careful operator	Calcareous loam on chalk	W. P. Bound, Gatton Park Gardens.
End of July and early in August	Satisfactory generally	Light and sandy on subsoil of pure sand	Rev. W. Wilks, Shirley Vicarage.
Apples, Pears, and Plums, second week in August (only laterals are pinched).	Good, if shoots are shortened to three leaves	Sandy and poor	W. H. Honess, Cobham Park Gardens.
End of July and early August (needs much discretion in choosing the proper time).	Very good	Light, almost gravelly loam	C. J. Salter, Woodhatch Lodge Gardens.
Apricots, last week in July; Apples, Pears, and Plums, early in August	Indifferent, except it allows the sun's rays to reach the fruiting spurs on trained trees	Light to clayey loam; subsoil sandstone impregnated with iron	Alex. Dean, Kingston.
SUSSEX.			
Plums and other stone fruits, middle of June; Apples and Pears, the first week in July.	Good	Flinty loam on chalk	G. Kent, Norbury Park Gardens.
First week in July, taking Apples first, and following with Pears, afterwards Plums and other stone fruits.	Very good	Poor, resting on sandstone	A. Reid, Poasingworth Gardens.
Plums and other stone fruits, early in July; Apples, the end of that month; Pears, in August.	Good	Retentive loam	W. H. Smith, West Dean Park Gardens.
All spur growths and side shoots when about 3 inches in length; Apples and Pears, generally in July.	Fairly good	Clayey loam, overlying yellow clay	W. Brunson, Brambletye Gardens.
About the second week in July	Good. Aids the development of the current season's fruits and the maturation of the wood	Mixture of loamy clay and sand	G. Grigg, Ashburnham Place Gardens.
Pears, Plums, and other stone fruits, third week in June; Apples, end of June.	Good	Light in texture and overlying chalk	W. Langridge, Ote Hall Gardens, Bury Hill.
Stone fruits, early in July; Apples and Pears, from middle of July ..	Fair	Subsoil of sandy rock	W. A. Cook, Leonardlee Gardens.
About the first week in July	Good	Heavy and fairly deep on yellow clay	E. Burbury, Arundel Castle Gardens.
WILTSHIRE.			
Pears, the first week in July; Plums and Apples, a week later	Good	Sandy loam on stiff clay	H. G. Prinsep, Buxted Park Gardens.
Plums, Apricots, Pears, and Apples in this order, from June 25 to July 15	Good	Marl and chalk on gravel	H. Gandy, Longleat Gardens.
Pears, June 1; Apples, June 15; Plums and other stone fruits, end of June.	Good	Light loam on sand	J. Bannerman, Lackham Gardens.
End of July	Good	Brash limestone	T. Challis, Wilton House Gardens.
Plums and other stone fruits, July 6; Apples and Pears, July 20 ..	Excellent	Friable loam on chalk or gravel	Geo. Brown, Bowood Gardens.
Middle of June, commencing with sweet Cherries and Plums, next Pears, finally Apples.			W. Tinley, Malmesbury.
			S. H. Tucker, Longford Castle Gardens.
7, England, N.W.			
CUMBERLAND.			
Second week in July	Few failures	Medium in quality, resting on clay	T. Tunstall, Carleton Hill Gardens.
End of July	Good	Clay subsoil	B. Gowan, Castle Gardens, Whitehaven.
LANCASHIRE.			
Upper half of the trees, before end of July; lower part, a fortnight or more later.	Good	Good soil on clay	W. P. Roberts, Cuerden Hall Gardens.
Early in July	Good	Heavy loam on clay	Preston.
Pears, July 5; Apples, July 15; Plums and other stone fruits, July 20	Good, but judicious root-pruning is better in many cases	Light loam on gravelly subsoil	E. F. Hazleton, Knowsley Gardens.
End of June and in July	Good	Moderately heavy on the red sandstone	W. Ashton, Wrightington Hall Gardens.
End of July; stone fruits other than Plums are not summer pruned ..	Practised only in the case of wall trees	Light lime-tone overlying rotten rock and clayey sammel	B. Cromwell, Cleveland Gardens, Althwa.
Last week in July	Fairly good	Dark, sandy loam on white sand	G. Tansley, Witherslack Hall Gardens.
WESTMORELAND.			
Second week in July	Advantageous if the roots are under proper control	Heavy soil, resting on clay	B. Ashton, Lathom House Gardens.
End of July	Good	Gravelly and thin	F. Clarke, Lowther Castle Gardens.
First or second week in July	Advantageous, but Plums require moderate pruning only	Principally limestone	W. A. Miller, Underley Gardens.
From middle of July to end of August		Heavy loam to a light, sandy soil overlying clay and gravel	W. Gibson, Levens Hall Gardens.
			James Coupland, Brougham Hall Gardens.
8, England, S.W.			
CORNWALL.			
Wall trees, early in August; orchard trees, in August and September ..	Good	Adhesive loam and clay	W. Sangwin, Trellisick Gardens.
DEVONSHIRE.			
Pears and Plums, middle of July; Apples, second week in August ..	Beneficial	Light loam on gravel	W. H. Bennett, Menabbly Gardens.
Middle of July to middle of August	Satisfactory	Good, heavy loam, sandy in parts	A. Hope, Exeter.
August	Very satisfactory	Very light, resting on the Devon waterstone	G. Baker, Membland Gardens.
Apricots, middle of April; Pears and Plums on walls, June 21; Apples, afterwards.	Good	Deep sandy loam on the red sandstone	J. Mayne, Bickton Gardens.
After the middle of July	Good	Heavy loam, subsoil sand, and, in parts, clay	T. H. Slade, Poltimore Park Gardens.
Stone fruits, August 8; Apples and Pears, August 15	Good	Stiff loam on clay	T. Seward, Saltram Gardens.
GLOUCESTERSHIRE.			
End of May	Aids maturation of fruit-buds	Stiff loam, on the blue lias	W. Kenn, Bowden Hall Gardens.
Cherries and Apricots, mid-June; Plums, July 1-15; Pears, July 15-31; Apples, July 30 to August 15.	Beneficial	Friable to clayey loam on the old red-sandstone formation	J. Banting, Tortworth Gardens.
The first week in July	Very good	Light loam on limestone brash	W. Nash, Badminton Gardens.
Wall trees, the last week in June	Good	Loam on limestone	F. Walton, Stanley Park Gardens.
End of July	Good	Heavy soil on blue clay	Westonbirt G.
At intervals from beginning of June until August (Peaches, Nectarines, and Morello Cherries are disbudded, not pinched).	Good, when done in conjunction with occasional root-pruning	Strong loam on clay	ley Car.

RESULTS OBTAINED FROM THE SUMMER PRUNING OF FRUIT TREES—(continued).

DATE CONSIDERED BEST TO COMMENCE SUMMER PRUNING OF APPLE, PEAR, AND PLUM TREES, &c.	GENERAL RESULTS FROM SUMMER PRUNING.	NATURE OF SOIL.	NAME AND ADDRESS.
8, England, S.W.			
HEREFORDSHIRE.			
Pears, Plums, and other stone fruits, beginning of July; Apples, from middle to end of July.	Good	Heavy loam on limestone	T. Spencer, Goodrich Court Gardens, Ross.
Second week in July, commencing with Apples and Pears, and continuing with stone fruits.	Best results		G. Mullins, Eastnor Castle Gardens.
Apples and Pears, the first week in August; Plums a little later ..			C. Smith, Barton Court Gardens, Colwall.
MONMOUTHSHIRE.			
Pyramid trees of Apples and Pears, during July; wall trees, early in June; espaliers, end of June.	Aids ripening of the wood	Cold, tenacious loam on heavy clay	W. F. Woods, Llanfrehfa Grange Gardens.
Early in July ..	Good	Clayey loam on marl, and, in places, clay	T. Coomber, The Hendre Gardens.
Plums and other stone fruits, from the second week in June; Apples and Pears, from first week in July	Very indifferent, but in lower situations near this place, and on sandy loam, results are beneficial	Strong, tenacious loam overlying boulder clay	H. Townsend, Maindiffe Court Gardens.
Apples and Pears on walls, in June; bush and pyramid trees, in August; stone fruits are not summer-pruned.	Not altogether satisfactory	Deep loam on red-sandstone	J. Basham, Fair Oak Nurseries, Bassaleg.
June and July ..	Favourable	Very heavy, and on the lias formation	W. Hallett, Cossington, Bridgwater.
WORCESTERSHIRE.			
Apricots, middle of July; Plums, Cherries, and Pears on walls, from middle of July; Apples in the open, middle of August; Pears, afterwards.	Good	Medium loam overlying the new red-sandstone formation	A. Young, Witley Court Gardens.
Last week in July ..	Satisfactory	Black garden-soil on sandstone	A. Pettigrew, Hewell Grange Gardens, Redditch.
Middle of July ..	Good	Heavy loam, bordering on stiff clay overlying red marl	W. Crump, Madresfield Court Gardens.
WALES:			
Pears, beginning of July; Apples, from middle to end of July; Plums, end of June.	Good	Heavy, on limestone	H. Weaver, Vaynol Park Gardens, Bangor, Carnarvon.
First and second week in August ..	Very satisfactory	Light, resting on hard rock	W. Speed, Penrhyn Castle Gardens, Bangor, Denbigh.
Wall trees, last week in July or first in August ..	No advantage in the case of standard trees	Light, overlying sand and gravel	W. Weir, Rhosnessney, Wrexham, Denbighshire.
Middle of July ..	Very satisfactory	Light loam, resting on gravel	J. Forsyth, Hawarden Castle Gardens, Flintshire.
Plums and other stone fruits, last week of June and first in July; Apples and Pears, afterwards.	Good	Light, dry loam, on gravel	E. Milner, Margam Park Gardens, Port Talbot, Glamorganshire.
Last week in July or first in August ..	Good; aids ripening of the wood and fruits	Stiff loam on clay	J. S. Higgins, Rhiliig Gardens, Merionethshire.
End of July or beginning of August; Plums just previous to these dates			J. Lambert, Powis Castle Gardens, Montgomeryshire.
First week in July, but varies according to season ..			G. Griffin, Slebeck Park Gardens, Pembrokeshire.
IRELAND:			
9, Ireland, N.			
Plums and Apricots, middle of July; Pears, last week in July; Apples, first week in August.	Good	Retentive, on clay	J. MacLean, Shanes Castle Gardens, Antrim.
Beginning of August ..	Good	Rich loam on limestone rock	W. Berry, Farnham Gardens, Cavan.
Peaches, Apricots, and Neotazines, early in July; Apples, Pears, and Plums, last week in July.	Very good	Stiff loam on a hard, calcareous subsoil	A. Campbell, St. Anne's Gardens, Clontarf, Dublin.
Not practised ..	Good	Light loam on adhesive clay	A. Porter, Woodlawn Gardens, Galway.
Apples and Pears, from middle of July to middle of August; Plums, the end of August.	Great improvement to wall fruit, especially stone fruits	Loamy, on hard, yellow clay	T. Dunne, Lough Cutra Castle Gardens, Galway.
Commenced, the middle of July; Apples and Pears, early in August ..	Good, when practised in conjunction with autumn root-pruning	Heavy, shallow, and cold, and approaching clay; deficient in lime	F. Connolly, Cranmore Gardens, Mayo.
Plums and Pears, June 10; Apples, June 24 ..	Good (helps to prevent canker in the trees)	Mostly a medium-heavy loam on cold, yellow clay	F. Walton, Sion House Gardens, Co. Tyrone.
Plums and Cherries, after the middle of June; Apples and Pears (laterals), early in July, leading shoots a month later.	Good	Gravelly, on a subsoil of pure gravel	G. Bogie, Pakenham Hall Gardens, West Meath.
Pears and Plums, end of June; Apples, end of July ..			W. Owey, Powerscourt Gardens, Wicklow.
10, Ireland, S.			
July 20 ..	Indifferent when compared with trees in the southern English counties; the abundant moisture causes the lower buds to grow	Light, on a gravelly, marl subsoil	F. Browne, Borris House Gardens, Carlow.
Late June or early in July, commencing with Cherries, and continuing with Pears, Apples, and Plums, in this order.	Good in the case of wall trees; no benefit to standard or named bush trees; Apples give immense crops in the open without summer pruning	Retentive clay and limestone rock	A. Barker, Carrigoran, Co. Clare.
Plums, July 6; Apples, Pears, and other fruit trees, mid-July ..	Good in every case; benefits the size, colour, and flavour of the fruits, and develops the fruiting spurs	Good, rich loam on limestone	C. Price, Michelstown Castle Gardens, Co. Cork.
Last two weeks in July ..	Indifferent; the practise is almost discarded in these gardens	Heavy, and impregnated with lime, on a bluish, marly clay	Thos. Bedford, Straffan House Gardens, Kildare.
Last week in July or early in August; small fruits, early in July ..	Good	Varies from good loam to sandy soil; the subsoil is gravel	F. France, Beasborough Park Gardens, Piltown, Kilkenny.
July 25 ..	Good	Clayey, on a retentive and bad subsoil	T. Rogers, Frenchpark House Gardens, Roscommon.
From July 20-31 ..	Good	Loamy marl	J. Doonan, Minella Gardens, Clonmel, Tipperary.
CHANNEL ISLANDS:			
Apples and Pears, by midsummer; stone fruits, by mid-July ..	With some kinds it is essential, with others it is not	Medium loam on decomposing granite	C. Smith and Son, Caledonia Nursery, Guernsey.
Not generally practised; a system of autumn pruning is more in use. The practice of "spurring" in September is justified by results. In Jersey the foliage of fruit trees generally often hangs until middle of December.			H. Becker, St. Saviours, Jersey.
July ..	Good	Good soil, 1½ feet in depth	R. Reed, Spring Grove, St. Lawrence, Jersey.
ISLE-OF-MAN:			
About the middle of July ..	Indifferent	Shelly, on a subsoil of blue and white clay	J. Inglis, Brunswick Road Nurseries, Douglas.

TREES AND SHRUBS.

LABURNUMS.

THE freedom in which these beautiful deciduous trees have flowered this season has caused much admiration. Many gardeners appear quite satisfied with the beauty of the common variety, but there are others that are superior in every respect, and that produce flower-sprays which measure from 12 to 18 inches in length. As individual specimens on the grass few trees can excel the beauty of Laburnums, and, if arranged in groups, their effect is visible for some considerable distance. They will also thrive and furnish a good effect by the water side, or when planted on slopes, in parks or woods. Many varieties of the common Laburnum (*L. vulgare*) are to be seen, but these are seedlings, and, in some cases, are scarcely worth planting. The named sorts are usually budded upon stocks of the common variety, and the union of stock and scion can be detected either within a few inches of the ground, or, if standards are required quickly, some 5 or 6 feet of the common stock is allowed to grow before the bud or graft is inserted. I mention this because I have seen some cases in which the stock had outgrown the scion, which had, therefore, died. A conclusion must not be arrived at too quickly in the case of the graft hybrid *L. Adamsii*, the purple-flowered Laburnum, if yellow blooms are found intermixed with them, for it frequently happens this particular kind has not only separate branches of yellow flowers, but the two separate colours, yellow and purple, occur on the same shoots (see *Gardeners' Chronicle*, September 24, 1904, p. 219).

The usual form of standard is not the only means whereby these Laburnums may be grown in order to display their flowers to advantage; pyramids, as an instance, are in some cases preferable, while the practice of training the branches thinly and nailing them to the walls of dwelling-houses, provides an attractive feature. They are also very suitable for covering arches and pergolas, and the long flower-sprays of the varieties *Vossii* and *Watereri* hanging above one's head produce an effect that well deserves the name of "Golden Rain" sometimes applied to varieties of Laburnum. Of several varieties grown in these gardens, the best is certainly *Vossii*. The trusses, in some cases, measure 24 inches in length, and it flowers profusely. This variety and all the other Laburnums flower freely in pots, and form excellent subjects for decorating the conservatory or dwelling-house early in the season. Next in order of merit is *Watereri*: the habit of the tree is close-growing, and it is a very beautiful kind, with long racemes of flowers of a pale tint, very freely produced, and remaining in good condition for a considerable time; this variety forms a good succession to the common kind. *Parksii* is a large-flowered variety, and somewhat darker in tint than the two already mentioned, but perhaps its most distinctive feature is its large, bright-green, glossy foliage, which is very much like that of the commoner autumnalis. The golden-coloured foliage and flowers of the same hue are pleasing in this variety, and, for small and large gardens alike, it should be used much more freely than at present. As a single specimen upon the lawn the Weeping Laburnum has a distinct charm, and, if it hangs over the water, it is even more effective. Other desirable varieties are *Alsingeri*, *crispum*, *Gumperi*, and *fragrans*. The present time is a favourable one to make a selection of varieties for planting in the autumn. *W. H. Clarke, Aston Rowant, Oxon.*

THE ALPINE GARDEN.

CAMPANULA GARGANICA HIRSUTA ALBA.

Few Alpine Campanulas are more satisfactory even in northern gardens than *C. garganica hirsuta*, where it appears to thrive even better than the typical *C. garganica*. The white-flowered variety, *C. g. hirsuta alba*, is still far from plentiful. In habit it is practically a replica of the blue form, but has white flowers and is of rather less vigorous growth. The plant is a good subject for a sunny rockery, or it may be planted in wall gardens. This little white Bellflower is increased by cuttings inserted in summer time. A mixture of sand, loam, and grit form a suitable rooting medium. *S. A.*

The Week's Work.

THE FLOWER GARDEN.

By A. C. BARTLETT, Gardener to Mrs. FORD, Pencarrow, Cornwall.

Hedge-pruning.—As soon as the deciduous subjects have completed their growth, the hedges should be pruned. This work is often, through press of circumstances, delayed until the current growth has become tough and hard to cut; the secondary growth is then made late in the autumn and, failing to become properly ripened, gets cut by early frosts. Whenever possible, the pruning should be done with a pair of secateurs in preference to using shears and hooks, which slice the leaves and give the hedge a very unattractive appearance.

Topiary work will now entail much labour in pruning, stopping, and tying-in. Great care and patience must be exercised, as an error of judgment would, for a season at least, spoil any beauty this type of gardening possesses. It is usual to entirely entrust this work to one man, who, as a natural result of practice and experience, can carry out the work with greater satisfaction than would be the case if several men were employed.

Border Carnations.—These plants usually bear such a profusion of flower buds that to ensure flowers of good quality it is necessary to thin out the buds, leaving from three to five on each stem. The stalks should be kept tied to slender, inconspicuous sticks. The surface soil should be frequently hoed, and if a dressing of artificial manure be applied at this stage it will be beneficial.

Wallflowers.—Transplant the seedlings into the reserve garden before they become drawn and crowded in the seed bed. The seed bed should be in a fairly open situation, and a liberal quantity of leafmould, or manure from an old Mushroom bed, should be forked into the top spit, so that the plants will "lift" with a good "ball" of soil next October, when they are moved to their flowering quarters. Plant them out in rows, drawn at distances of one foot, putting the plants 9 inches apart in the rows. The Dutch hoe may then be freely worked on the surface soil as occasion requires. As soon as the plants have become established, pinch out the leading shoot to induce a dwarf and compact habit.

Double Wallflowers need to be increased by cuttings, which should be moderately firm in texture, but not tough and wiry. When possible, secure shoots having a "heel" of old wood attached to them. They will be the more certain to make roots if they are firmly inserted in pots or boxes of sandy soil, and kept close in a cold frame. When roots have formed the plants should be planted out in the same manner as seedlings.

FRUITS UNDER GLASS.

By ALEXANDER KIRK, Gardener to J. THOMSON PATON, Esq., Norwood, Alloa, Clackmannanshire.

Pineapples.—Early started Queens, from which the fruit has been cut, should have the suckers detached, and these suckers should be potted up into 6-inch pots. The old plants may afterwards be thrown out. Provide each pot with perfect drainage, and pot the suckers firmly in turfy loam. Plunge the pots in a bed having considerable bottom heat, and the plants will soon make roots. Shade them from bright sunshine, and keep the house close and the atmosphere moist. Suckers that are already well rooted should now be potted into the pots in which they will fruit next year.

Plants that are swelling their fruits require a moist atmosphere, and a temperature of 95° during the day and 80° at night. When air has been admitted during the day, let the ventilators be closed again early in the afternoon. Afford manure water in a tepid condition twice each week to all such plants.

Figs.—As soon as the crop is gathered, supply the plants with manure water whether they are growing in pots or borders. Apply a fresh mulch of short stable litter in order that it may assist in the development of the second crop. Syringe the trees freely, maintaining a moist atmosphere, and guard against the appearance of red spider.

Peaches and Nectarines.—Where early crops have been gathered, syringe the trees three times

a week, and if red spider has been troublesome syringe every day with a solution of soft soap, hot water, and sulphur, as directed in a previous Calendar. This will keep the foliage fresh and clean throughout the summer. Keep both top and bottom ventilators open both night and day. If the borders are found to be in the least dry give them a thorough watering. A most important item in their culture at this season is to thin out the shoots wherever the trees appear to be overcrowded with young wood. Remove bare shoots and those that will not be required to tie in for next year's crop. This system of pruning prevents "gumming," and allows the remaining shoots to become thoroughly matured.

In the later house, where the Peaches and Nectarines are stoning, the trees require to be kept comparatively cool, as they must not be hurried at this particular stage. Examine the trees and give the fruits a final thinning, always leaving those fruits which are placed on the upper side of the shoot. Syringe the trees until colouring commences night and morning, except where mildew is feared; in such cases, the afternoon syringing must not be practised. The atmosphere can be kept humid by partly closing the house early in the afternoon. Tie in all young growths it is wished to retain, but cut out any that are of extra and undesirable strength. Keep a sharp look-out for red spider.

THE KITCHEN GARDEN.

By WILLIAM H. HONESS, Gardener to C. COMBE, Esq., Cobham Park, Surrey.

Peas.—Plants raised from the sowings made last November will now be in full bearing. We commenced on the 6th inst. to gather Peas from the variety Little Marvel sown in November and cultivated on a south border. Continue to make further sowings for producing late supplies. All plants that are well advanced in growth should be given a good mulching of stable litter. If the weather becomes dry afford them a good soaking of water, and syringe them overhead early in the evening. This will greatly assist the pods to set and the Peas to develop; make another sowing of Sugar Peas if this type is appreciated. Sugar Peas should be afforded the same liberal treatment as is advised for ordinary Peas, for if neglected in dry seasons the plants soon become exhausted.

Brussels Sprouts.—If the work has not already been done, the main crop of these should be planted out at the first opportunity, for undoubtedly this is the most appreciated of all winter vegetables, and failure, or but indifferent results would cause great disappointment.

Broccoli and late Cauliflowers.—Make further plantings of these, and all other winter vegetables. Afford them waterings in the event of dry weather occurring before the roots get well established in the soil, and if the surface of the ground should become "caked," this must be broken by the use of the hoe. Should the weather remain showery, frequent hoeings will be all that are necessary.

Leeks should be planted out at once in ground which has been prepared previously. Plant them in rows made from 6 to 12 inches apart, in holes which should be deep enough to contain the plants so that the base of the leaves only will appear above ground. If the soil is very dry at the time of planting, it will be well to pour water into the holes before inserting the plants.

Carrots.—Early varieties should be sown now for drawing whilst young, and if another sowing be made a little later on, in a border where they can remain throughout the winter, if covered with a few leaves, the crop will be found very serviceable.

Onions.—For the raising of young plants for use in the making of salads, seeds should be sown at frequent intervals, as it is advisable to have these young and tender.

General work.—Close attention must be given to all crops in the kitchen garden, in the matter of keeping them free from weeds; the surface soil should be broken frequently, and a loose, crumb-like layer kept as a surface. If watering has to be resorted to, this work must be done thoroughly, and it must be repeated at intervals until a heavy rainfall occurs, when it may cease to be necessary.

PLANTS UNDER GLASS.

By J. G. WESTON, Gardener to H. J. KING, Esq.,
Eastwell Park, Kent.

Cyclamen.—If the early batch of seedlings have not been placed into the pots in which they will flower, no time should be lost before doing this work, as the plants will be expected to commence flowering in autumn. Choice flowers are especially valuable late in autumn, and it is doubtful if many plants are capable of giving better returns at that time than may be obtained from well-grown Cyclamen. For the potting mixture use a compost consisting of two parts fibrous loam and one part leaf-soil, adding sand, charcoal, and a little dried cow-manure. Return the newly-potted plants to a frame that will not be fully exposed to the sun's rays. In any case careful attention must be given to providing the plants with proper shade. Arrange them thinly in the frame in order that the air may easily circulate amongst them; with this object in view it is a good plan to stand them on inverted flower-pots. When the plants are well established and growing freely the lights may be drawn entirely off in the evening, the cool night dews being very beneficial to Cyclamen. Replace the lights early on the next morning. Many growers advise throwing the old plants away after flowering, but this is a pity unless the space is required. I usually select the best forms when the plants are in flower and retain these for another season, discarding those only which are inferior. These two-year-old plants always bloom splendidly. These should also be potted up, taking care not to destroy the roots, which on examination will be found to be active. We do not dry off the corms so severely as was the practice formerly, and after they are repotted, the old plants are treated similarly to seedlings. Keep a look-out for thrips and aphides, fumigating regularly to prevent these pests obtaining a footing.

Scutellaria Mocciniana.—For brightening up the stove a few well-grown plants of this species are very useful. It is fairly easy to propagate, young shoots taken off half ripened wood rooting readily. When ready for potting a compost consisting of turfy loam, manure from a spent Mushroom-bed with charcoal and sand added, will be found suitable. Pinch the tops of the shoots once or twice to ensure a good habit in the plants, and in the spring cut back old plants fairly hard, keeping the roots drier than usual. When the young growths are about an inch long repot the plants, giving them a fairly good shift. The plants will require but little more attention than is necessary to keep them clean.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower to Sir TREVOR LAWRENCE,
Bart., Burford, Surrey.

Heating, shading, and ventilation.—Up to the present time the weather has not been favourable generally to the growth of Orchids, especially tropical species, which delight in a great amount of sun-heat. Opportunity should be taken on warm, sunny afternoons to give the plants which occupy the warmest division generous treatment in every respect. Close the house and draw up the blinds as early as may safely be done without causing injury to the plants, so that the atmospheric temperature may rise to between 80° and 90°, or higher if the sun is sufficiently powerful. At the same time thoroughly damp the stages and floors, particularly under and near the hot-water pipes. If the roof glass is stippled, as advised in a former Calendar, the blinds may be raised soon after 3 p.m., but plants that have no such protection from direct sunshine should not be exposed to its influence until 4 p.m. at the earliest, or even half an hour later. In a mixed collection it is difficult to suit all the various species, &c., in this division as regards shading, but if the tender-leaved plants are placed at one end of the house, they may easily be protected from the sun with ordinary garden mats after the blinds are taken up. Such species as the deciduous Calanthes, Dendrobium, Catasetum, Cynoches, Mormodes, Schomburgkia, terete-leaved Vandas, and others of the same habit of growth as Scuticarias, &c., also Lissochilus, Eulophias, Cyrtopodium, Renanthera, &c., thrive in almost an unlimited degree of sun heat. While such genera as Cypripedium, Phalenopsis, Angreum, Aërides, Saccolabium, Cirrhopetalum, Bulbophyllum, Phaius, &c., also revel in the tropical warmth, they require much more shade than the others. It is essential

that all of these plants, with the exception of Phalenopsis, that are now making their growth, should be well supplied with water, particularly Dendrobiums that are making many roots, because if these are allowed to become too dry at the root, the young shoots may get a check that would cause them to finish up prematurely, and then to start a fresh lot of young breaks, which would cause the plants to bloom unsatisfactorily. Immediately after closing and damping the house, it is advisable to afford these Dendrobiums a good syringing with tepid rain water, directing the water well up under the leaves, which will assist to promote healthy growth, and to keep the foliage free from red spider and other insects. Should red spider make its appearance, it must be immediately eradicated. My practice is to take every plant down and well syringe the foliage with Gishurst's compound, mixed according to the directions given by the manufacturers, and adding XL-All liquid insecticide at the rate of one part to 20 of the former mixture. The preparation should be applied at a temperature as warm as it is possible to bear one's hand in. When syringing the foliage hold the plant over a large bath, so that none of the mixture will be wasted, and immediately after each plant has been cleansed, give it a thorough syringing with clean tepid rain water. After closing the house early in the afternoon with sun heat, the atmospheric temperature will rise to the figures mentioned above, and probably higher, but it should gradually fall during the evening, and the last thing at night, if the weather is suitable, a "chink" of air may be admitted through the top ventilators, leaving these open all night, so that by early morning the thermometer will register about 70° of heat.

THE HARDY FRUIT GARDEN.

By J. MAYNE, Gardener to LORD CLINTON, Bicton,
East Devon.

Pears.—Some varieties in these and other local gardens require the fruit to be thinned, but others have been severely thinned by the Pear midge, a pest that cannot be easily exterminated. Trees that are annually attacked, after due precautions have been taken in respect to spraying, &c., should be removed to fresh sites in the autumn. This would tend to lessen the numbers of the pest, especially if the old soil is removed and the trees are replanted in fresh soil. Secure all leading shoots to the wall or trellis where there is still room for extension, and apply manurial waterings to trees growing against hot walls, as the rainfall is always exceptionally light near to the base of a wall.

Peach and Nectarine trees should be assisted with frequent manurial waterings during the next few weeks, the stoning process causing a great strain upon the trees. Good crops appear general this season. Owing to so much cold and sunless weather black fly has proved troublesome on some of our trees, causing us to make frequent applications of quassia extract, followed up next morning with a thorough washing with clear water so that no stain shall be left on the fruit. Continue to regulate and train the young shoots, pinching out any lateral growths. Relieve any pressure there may be on any of the swelling fruits. Expose the fruits of early varieties of the Peach, such as Waterloo, Amsden June, and Alexander, as well as Early Rivers Nectarine (one of the best for outside culture), in such a manner that the rays of the sun will reach them. Do not rely on the frequent showers to keep the trees free from red spider. It being underneath the foliage that this pest makes its appearance, the periodical syringings twice or thrice each week should still be carried out.

Morello Cherries.—The shoots will now require to be trained in the direction they are to take, which may be quickly done by using similar material as advised for the Peach three weeks ago, care being taken that the young shoots are not damaged in the operation. Pinch at the fourth leaf any shoots retained to form spurs, and the points of any leading shoots that will be cut away later in the season. The quassia extract must be persevered with if black fly is still in evidence. Most of the recent rains have come from the south or south-east, so have not benefited much those fruit trees

which are growing on north aspects, a position usually, and I think rightly, allocated to the Morello Cherry. Manure water, as in the case of the Peach, will assist the trees greatly at this season, and there is no better stimulant than that to be obtained from cow manure or the stable-yard, the former for preference. Unless very hot weather sets in a mulch is unnecessary for trees growing in these cool positions, especially if the surface soil is frequently stirred with the flat hoe, or pricked up with the fork so as to prevent it getting hard and therefore cracking. If it is thought necessary to apply a mulch, it should consist only of light, strawy litter.

PUBLIC PARKS AND GARDENS.

By W. W. PETTIGREW, Superintendent of the Parks and
Open Spaces in the City of Cardiff.

Birds.—The bird-life in a park, whether introduced, semi-domesticated waterfowl, or native wild birds, is a source of pleasure to most visitors. Everyone is more or less susceptible to the charm of the notes given forth by native songsters, and during spring and early summer birds are by no means the least attraction a park may possess. The interest that they evoke is not confined to their songs, for their very appearance, coupled with the fact that they are living, moving creatures, always make them attractive objects. Although there is nothing musical in the note of the duck or swan, yet these birds are a source of pleasure and amusement to the younger visitors.

How to encourage birds.—Few creatures seem to realise when they are in a safe asylum so quickly as do wild birds. In public parks, where all birds are more or less free from molestation, the most timid and wary species, as a rule, throws off its shyness and appears boldly in the open. A good illustration of this is often seen in some of the busiest London parks, where that most shy bird, the wood-pigeon, feeds quite unconcernedly within a few yards of visitors. The "dab-chick," or lesser grebe, the coot, and the moorhen—all naturally very shy birds and difficult to approach in their wild haunts—have become constant park habitués, the first and last breeding freely in some of the most frequented places where ponds or lakes exist. In this neighbourhood kingfishers, wood-peckers, tufted-ducks, poachards, widgeon, and teal are regular visitors to the parks, and disport themselves so openly that the public has become quite familiar with their appearance. The kingfisher has bred regularly for many years past within a few yards of one of our fish hatcheries. Although it has on several occasions been caught making too free with the young trout, its rarity and beautiful plumage have saved it from well-merited punishment.

Greater interest in habits of birds.—Apart from what may be considered the sentimental regard for wild birds which is common to us all, a large and increasing section of the public takes an interest in them by, among other things, studying their distribution and migratory habits. So popular has ornithology become that few park guides are published now which do not include a list of the various kinds of wild birds observed in the park from time to time. Daily newspapers also appreciate the interest taken in this subject, and are ready to publish any information sent to them regarding the presence of rare, or the arrival of migratory, birds in the locality. It is pleasing to note that this increased scientific interest is not accompanied by a craze for collecting, and few are more persistent in their denunciation of the destruction of rare birds than true ornithologists. A few living specimens in a free state are usually of far more actual interest than a whole collection of stuffed ones. Notwithstanding the fact that most birds are looked upon as very bad gardeners, and are ruthlessly destroyed in many private gardens, they can do but little damage in a park. They should not merely be protected, by prohibiting birds-nesting, netting, and the use of the catapult, but where possible every facility should be given the birds for breeding. In the vicinity of water, reeds may be planted in many out-of-the-way corners where they could easily be left intact when cleaning-up operations take place in the autumn. These could afford protection to many kinds of birds during the winter, and nesting places for them in spring.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Special Notice to Correspondents.—The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.

Illustrations.—The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but he cannot be responsible for loss or injury.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY, JUNE 24—Midsummer Day.

TUESDAY, JUNE 25—
Roy. Hort. Soc. Coms. meet.
Brit. Gard. Assoc. Ex. Coun. meet.

WEDNESDAY, JUNE 26—
Colchester Rose Sh.
Richmond Fl. Sh.
Reading Rose Sh.

THURSDAY, JUNE 27—
Isle of Wight Rose Sh. at Shanklin (provisional).
Canterbury Rose Sh.

FRIDAY, JUNE 28—Roy. Bot. Soc. meet.

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich—61° 3'.

ACTUAL TEMPERATURES:—

LONDON.—Wednesday, June 19 (6 P.M.): Max. 67°; Min. 51°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—Thursday, June 20 (10 A.M.): Bar. 29.9; Temp. 61°; Weather—Bright.

PROVINCES.—Wednesday, June 19 (6 P.M.): Max. 62°; Lancaster; Min. 56°, Bedford.

SALES FOR THE ENSUING WEEK.

WEDNESDAY—

Palms, Bays, Ferns, and other plants, at 1; 100 lots of Dwarf Japanese Trees, at 2, by Protheroe & Morris, at 67 & 68, Cheapside, E.C.

At the present season the question of the desirability or otherwise of summer pruning is doubtless receiving attention from those engaged in the cultivation of fruit trees. Of late years the practice has apparently become more general, and so far as our information goes there are few cultivators of high-class fruits that do not prune some of their trees, in more or less degree, whilst they are still in leaf. It is generally recognised, however, that trees which are grown without any root restriction, and that have ample room for branch development, need no summer pruning, and in any case it would be impracticable to attempt to apply the system to standard trees in the orchard. All the pruning such trees require is an adequate thinning of their branches, that thereby the trees will continue in such a condition that most of the shoots will be exposed to the rays of the sun, and to the influence of the air as it circulates freely among them. Every fruit-grower should know that thinning is necessary in order that the leaves may be able to properly discharge their functions in respect to the elaboration of the sap, to ensure the thorough maturation of the shoots

before winter, and the development of the buds to the degree essential for the production of good crops of fruit. This system suits the type of tree we have mentioned very well, but it will be admitted that it is not a method that best secures regularity in the crops, or that may be depended upon to produce fruits of the finest size and quality. It answers satisfactorily the purpose in view, which is the production of fruit crops under the simplest and least expensive conditions.

Fruit trees are grown under many diverse circumstances, and in the cultivation of almost every other form of tree, whether cordon, espalier, wall, pyramidal or bush, some degree of training is adopted. Following the practice of training, which in every case imposes some degree of restriction in growth, summer pruning has become part of the recognised yearly treatment. Severely trained trees are grown in limited areas, and the various operations to which they are subjected are always of an artificial nature, for pruning of any description, and in any season, is admittedly artificial. If a gardener were asked for his reason for pruning at all, he would probably justify the practice by the object he has in view, that of fruit production, to secure which result it is necessary that the production of wood growths should be restricted. It is an attempt to divert the natural forces within the tree into channels that favour the objects of the fruit-grower rather than those of the tree itself.

One fact in regard to summer pruning appears incontrovertible; the more restrictive the general treatment to which a tree is subjected, the greater need there is for removing part of the growth in summer. Thus, if we take an extreme case, the trained trees against walls or on trellises, owing partly to the branch pruning they receive, almost invariably make such a quantity of "breastwood" that it becomes imperative to stop such growths when they have made a few leaves, in order that the fruits may have an opportunity to ripen, and the lower buds on the new shoots become sufficiently exposed to the sun and air.

In respect to espalier, and even bush, and pyramidal trees, it is claimed that by summer pruning the current season's shoots are made to produce ultimately fruit, through the creation of flower buds or "spurs," from what are primarily merely wood-producing buds, and would remain such in the absence of pruning. It may also be urged, and with good reason, that if trees which produce a large number of long shoots are left untouched until winter, and most of them are then shortened or cut out, the trees may be expected to produce as much useless wood in the following summer as hitherto. By summer pruning the tendency to make such growth is not increased as it would be by severe winter pruning; it is rather diminished.

But the gardener has another means of controverting such a tendency, and it consists in root-pruning. Theoretically, it may be advanced that if branch-pruning and disbudding are practised upon a tree for any considerable length of time, a condition is brought about which renders it necessary to prune the roots in order to bring about the balance or proportion between the root system and branch development that is

necessary for fertility. Root-pruning, however, is laborious work, and, therefore, expensive, and how often it should be employed in the place of summer pruning is a matter for the judgment of the individual fruit grower after consideration of the particular circumstances in his case. At the best, root-pruning is a treatment of an occasional kind only, but summer pruning is much more easily performed and can be carried out every season.

In summer pruning the operator has to distinguish carefully as to the best time of growth for carrying out the work. The purpose being to cause the buds on the lower part of the shoots so pruned to become perfectly matured, it is important that the pruning should not be done so early in the season that such buds will be forced into growth during the same season, for the result of this would be that the ripened buds being forced into growth, new shoots would form, upon which the buds would be very immature at the commencement of winter. It might, on the contrary, be done too late for the operation to be followed by the good effects desired.

For these reasons, and because we had grounds for believing that there was much divergence in the opinion of gardeners as to the choice of dates for the practice, we collected last autumn the opinions of many correspondents who take special interest in fruit cultivation. The information they obligingly sent us we reproduce in the present issue as affording to every fruit grower some details of the practices followed by others engaged in the same pursuit as himself. The exact questions submitted to our correspondents were as follow:

(1) What date is, generally speaking, the best in your district to commence summer pruning of—(1) Apples, (2) Pears, (3) Plums and other stone fruits?

(2) Are the general results good or indifferent?

(3) What is the nature of the soil and sub-soil?

Reference to the tables will show that the replies to the first question vary considerably. Some operators commence summer pruning in June, others in August, but the great majority do so in July. It does not seem possible to perfectly explain the discrepancy of the difference in locality, or the character of the soil where the trees are growing, though these circumstances may be expected to have some bearing, at least, on the subject. It appears highly probable that, whilst some growers prune too early, others commence too late to obtain the best results. Plums are generally treated before Apples and Pears.

The answers to the second question indicate that the great majority of cultivators of first-class fruit believe that summer pruning is beneficial, for, whilst more than 150 reporters state that the results are satisfactory, only 35 express doubts on the efficacy of the practice. It seems likely that summer pruning is least called for in gardens where the soil is of a light nature and rather poor, especially if these conditions exist in localities where there is usually a considerable amount of sunshine, because in such cases the trees are not likely to make an excessive quantity of growth.

RHODODENDRON, DUKE OF CORNWALL, RECOMMENDED AN AWARD OF MERIT BY R.H.S.
ON MARCH 19 LAST; COLOUR OF FLOWERS, BRILLIANT RED WITH DARK SPOTS.

It may be remarked here that the experiments carried out on the Duke of Bedford's experimental fruit farm have not been favourable to summer pruning. In the Seventh Report of the Woburn Fruit Farm (1907) reference is made to the subject, and it is stated that there is nothing further to add to what was recorded in the Fifth Report, but it is admitted that "so much depends upon the character of the season and soil, on the nature of the varieties, and on the actual date of treatment, that it is impossible to give any certain pronouncement on the strength of the result available up to the present. It is intended to make other experiments on a more extensive basis in the immediate future." On the contrary, an experienced fruit grower, writing to us on the subject of summer pruning, states that, "with the retention of good leafage on the spur, there is developed through active sap agency a change in the nature of hitherto dormant leaf buds, and ere the leaves fall, these buds have become changed from mere shoot-producers into incipient fruit buds, and, if in the winter the spur be cut back to but two such buds, one or both will swell up the next year, and thus become effective fruit buds."

Naturally, the circumstances are different in the case of Peach and Nectarine trees, Morello Cherries, and Black Currants, all of which produce their fruits on shoots of the previous season's growth. Therefore, in these cases, not summer pruning, but ordinary thinning out or removal of crowded shoots is required. There are certain varieties of Apple, also, which bear at the ends of the shoots, and these should be exempt from summer pruning. It is good practice to commence summer pruning at the top of a tree, and complete the pruning of the lower branches a few days afterwards. Many careful fruit growers have found that good results follow a system of summer pruning, which consists merely in twisting the shoot partly off, allowing the end to hang down until it is cut off in the winter. The effects appear to be better than if the end of the shoot is cut off in summer, but the appearance of the trees thus treated is untidy and the practice is scarcely one that is likely to be adopted generally.

We do not know that any positive conclusions can be drawn from the details our correspondents have been good enough to furnish, but, at the least, they represent the opinions of numerous experts, and are, therefore, worthy consideration from those who are interested in the subject of summer pruning.

OUR SUPPLEMENTARY ILLUSTRATION to the present issue is reproduced from a sketch made by Mr. WORTHINGTON G. SMITH of a hardy Rhododendron which was shown at the meeting of the Royal Horticultural Society held on March 19 last. It was exhibited on that occasion by Mr. R. GILL, Tremough, Devon, who informed us that the parentage of R. Duke of Cornwall was that of a variety of R. arboreum, crossed with the species R. barbatum. The leaves of "Duke of Cornwall" are 10 inches long, 2 inches across at the widest, and almost smooth on the under surface. The variety is specially valuable for its brilliant colouring, the brightly-tinted red lighting up grandly under the rays of the sun. The illustration shows that the flower-truss is compact and shapely, and the variety will undoubtedly be welcomed, its hardiness being equal to that of R. Pink Pearl or R. X Kewense.

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the committees will be held on Tuesday, June 25, in the Hall in Vincent Square, Westminster. In the afternoon, at 3 o'clock, a lecture will be given on "Peculiarities of Leaf Arrangements."

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—The 68th Anniversary Festival Dinner, in aid of the funds of this institution, will take place at the Hotel Metropole, London, on Wednesday, June 26. The Hon. WALTER ROTH-SCHILD, M.P., will preside, and will be supported by, amongst others, the Rt. Hon. MARK LOCKWOOD, M.P., Alderman Sir MARCUS SAMUEL, Bart., Sir EDGAR SPEYER, Bart., Sir E. D. STERN, Sir CLIFTON ROBINSON, J.P., Sir GEORGE BARHAM, STUART M. SAMUEL, Esq., M.P., EDWARD TERRY, Esq., &c., &c. Contributions, to be placed on the chairman's list and announced at the dinner, will be thankfully received by the treasurer, HARRY J. VEITCH, Esq., 34, Redcliffe Gardens, South Kensington; the bankers, Messrs. GLYN, MILLS, CURRIE & Co., Lombard Street, E.C.; and the secretary, Mr. GEORGE J. INGRAM, at the offices, 175, Victoria Street, Westminster. We hope all our readers will do their utmost to make this event successful. In order to place the committee in a position to provide for the necessitous candidates a larger income than heretofore is absolutely necessary.

SUMMER PRUNING IN THE TRANSVAAL.—Too little attention has been paid in the past to the systematic pruning of all fruit trees in the Transvaal, either in winter or summer, and consequently we find that the fruit produced here, though sometimes plentiful in quality, is almost always lacking in size and appearance. Summer pruning is one of those operations which has become popular comparatively recently. Its extensive adoption in California originally was caused by the fact that, when practised, it sometimes had the effect of making the Moorpark Apricot, which is there a somewhat shy bearer, produce crops more regularly. Success in that direction led to a more extended use of the practice, and now it is applied in a more or less general manner to Apricots, Peaches, and Plums with similar intent. The right time for this operation to take place has been a matter of much discussion, and a good deal depends upon local circumstances. In this Colony it will be generally acknowledged that all trees have a tendency to make a rampant growth during our hot and usually wet summer months. One result of this is that, if left untouched until the ordinary winter pruning, a good deal of the energy of the tree has been wasted, in so far as the producing of fruit is concerned. Another is that the heavy top growth tends to render the tree more helpless in case of the high winds which are sometimes prevalent, as, owing to the extra leverage, the wind obtains greater power, and blows the limbs about in such a manner as to cause serious damage to both the tree itself and possibly any fruit that it may be carrying. Another reason for summer pruning is present in considering the form one wishes the tree to assume. Oftentimes one or two branches will display a tendency to much more rapid growth than the others, and it is advisable to stop these by pinching off the tops with the thumb and finger, thus reducing the whole growth to some degree of symmetry. A frequent trouble is the "Water Sprout," a long, straight-growing, greenish-looking shoot, which is liable to start up from the interior branches of the tree. These should be removed entirely by cutting them off close to the base, either with a knife or pair of pruning shears; they only run away with an amount

of sap which should proceed in the ordinary channels to help support the entire head of the tree. It is, further, a good plan to remove by rubbing off in the early stages any incipient growths of new limbs which show themselves in places where they are not desired; this also helps to strengthen the top, whilst, at the same time, preventing undue crowding in the centre of the tree. It will be seen, therefore, that there are three prominent reasons why summer pruning should be practised. As a rule, it is safe to commence that operation, when intended to induce regular bearing, as soon as the fruit is picked. When the object to be attained is the strengthening and general conservation of the energies of a tree, it may be performed at almost any time during the growing period, when it appears that the tree is getting out of hand. If practised before an unduly heavy growth has been made, the necessary work may be done by simply nipping off the ends of the green shoots; this has a tendency to the formation of fruit buds, as well as to mature the growth already produced. If the branches have attained some considerable thickness, recourse must be had to the pruning shears, and a general lopping off of superfluous growth undertaken. When merely intended to conduce to the general appearance or symmetrical form of the tree, the necessary work may be done any time when the limbs which seem undesirable make themselves unduly prominent. It is also a good plan to cut back all new growths from grafts put in during the previous winter or spring to a reasonable limit, say 18 inches or thereabouts, and, if necessary, a further shortening in may be resorted to later.

RHODODENDRON EXHIBITION IN THE ROYAL BOTANIC SOCIETY'S GARDENS.—The exhibition of Rhododendrons by Messrs. John WATERER & SONS, LTD., of which a note was published in our last issue, will remain open until the end of the present month. A splendid effect is made with plants of R. hybridum in the sunken exhibition area, the plants in tubs, pots, or without receptacles at all, as dug up from the open ground, being formed into groups of irregular shape, with borders surrounding them. These are arranged in somewhat compact masses, sloping from the front backwards, the taller plants being standards of chiefly older varieties, and every plant, new or old, is flowering abundantly. Owing to the ground being raised at the ends, the whole exhibition can be seen at once. A few foils to the masses of bright tints are afforded by standard trees of variously tinted foliage, and the introduction of such plants as Kalmia latifolia, Viburnum plicatum profusely flowered, and hardy Azaleas. It being impossible to give a list of all the beautiful varieties observed, it will suffice to notice a few of those which appear most remarkable and distinct. Baron Schröder has flowers of a purplish tint, with a yellow blotch. Concessum has a light centre, bordered with rose colour; Cynthia is rosy crimson and has a fine large truss; delicatissimum is a well-known light coloured flower, very showy; Earl of Shannon has flowers of dark crimson, and they possess fine shape; fastuosum is a semi-double flower of light lilac tint; Frederick Waterer has large flowers and truss, and is coloured bright crimson; Gomer Waterer is white, with a slight flush, and the flowers are produced in a very large truss; John H. Agnew is pale blush, with brown spots; Kate Waterer is of clear crimson-rose; Michael Waterer, bright crimson, of extra fine form and habit; Mrs. John Clutton is a clear white flower; Mrs. Tom Agnew, white, with a blotch of pale yellow; and Princess Hortense has lilac-rose coloured flowers, produced in extremely fine trusses.

* Extract from a leaflet issued by the Transvaal Department of Agriculture.

THE LATE DR. MASTERS, F.R.S.—The Rev. W. WILKS, M.A., has addressed the following letter to the editor of the *Times*:—"Sir,—My excuse for addressing this letter to you is that all England has of late years been roused to a love of Nature and gardens, and the *Times*, more than any other paper, reaches all England. The whole gardening community has undoubtedly experienced a very great loss by the death of Dr. MASTERS. I am old enough to remember him as a comparatively young man—indeed, I distinctly remember his father before him—and during my life-time (the whole of which has been intimately connected with garden pursuits and interests) I do not think we have ever had a man with such a combined capacity, willingness, and aptitude for instructing us everyday gardeners in the bearing and application of science as regards gardening. It is an exceedingly common failing with all teachers to teach over the heads of their audience, and this, I think, is specially noticeable in men of high scientific attainments. They seem to be so immersed in scientific terminology as almost to think in technical phrases, and so become almost, if not quite, unable to express their meaning in terms and in words which we, 'the vulgar,' can appreciate. Dr. MASTERS was quite the opposite. I never knew anyone who could present a natural law or a scientific discovery and their bearing on the art of horticulture in such simple, every-day language, easy to be understood of the people. He combined, as I said, the capacity to instruct, with the willingness to impart, and, best of all, with the aptitude of *how* to instruct; and he never minded condescending to explain in the most simple words of the people. His loss, therefore, is great, and I think that all who love gardens ought to do something to perpetuate his memory, and what I would venture to suggest as the most fitting memorial issues directly from what I have said of him. Just as there are foundation lectures in law, in medicine, and in theology, so let us establish 'The Masters Lectures' on the application of science to horticulture. Let us raise a fund sufficient to provide an adequate fee acceptable to the most renowned scientists among us to deliver a series of three or five lectures annually, the lectures to be delivered in the first instance before the Royal Horticultural Society, and to be afterwards printed and circulated amongst all the gardeners' mutual improvement and similar societies throughout the land. In this way we should not only perpetuate the memory of our good friend, but also his work—a point which he himself, with his habitual modesty of demeanour, would, I am certain, have considered of far greater importance. If this suggestion of mine meets with the general approval of those who knew Dr. MASTERS personally, or through the *Gardeners' Chronicle* (of which he was for so many years the distinguished editor), I shall be happy to join with them in its promotion.—W. WILKS, Vicar of Shirley, Sec. R.H.S., Shirley Vicarage, Croydon."

TRANSPLANTATION OF AN OLD YEW TREE.—In consequence of the transference of the Botanical Garden of the Senckenburg Natural History Society in Frankfurt-on-the-Main from the interior of the city to the Ginheimer Höhe, the removal of the great Yew tree, planted 300 years ago, was decided upon, and was actually carried out by the Frankfurt building firm of Messrs. PHILIPP HOLZMANN & Co. The work lasted from May 24 to May 30, 1907, so difficult was the passage of the enormous mass through the streets to the new situation. The tree had been gradually prepared for removal during the three previous years by cutting through the roots and encouraging the formation of young roots at the wounded ends by the introduction of rich soil, a work that was carried out by Mr. RUDOLF GUNTHER, the head gardener. This

operation had reduced the size of the ball to about 4 metres square and 2 metres in depth, and having a total weight of tree and soil of 40 to 45 tons. The distance to be travelled was 3½ kilometres. It may be of interest to state that advice was sought from Messrs. W. BARRON & SON, Derby, a firm which has had much experience in the removal and transplanting of large trees. [See *Gardeners' Chronicle*, April 6 last, p. 222.] The representative of this firm gave advice in the same sense as the earlier specialists who were consulted, and which could only be followed in part. The ball, a quadrangular mass, was securely boxed-in on all sides, and placed upon four baulks of strong timber, under which were placed several rollers. The hauling power consisted of a steam-driven street roller. The operations are recounted and illustrated in *Die Gartenwelt* for June 15.

HORTICULTURAL COLLEGE, SWANLEY.—The prizes will be presented to students on Friday afternoon, July 12, by Sir WILLIAM HART DYKE, Bart. Sir JOHN COCKBURN, K.C.M.G., will take the chair at 4 o'clock.

AGRICULTURAL EDUCATION.—The Departmental Committee, of which Lord REAY is chairman, held meetings on the 11th, 12th, and 13th inst. Representatives of the Cumberland and Westmoreland Farm School, Newton Rigg; the Agricultural College, Aspatria, Cumberland; the University College of Wales, Aberystwyth; the National Fruit and Cider Institute, Long Ashton, Bristol, and of the Agricultural Committee of the Gloucester County Council attended and gave evidence. On the 12th inst. also the Committee heard evidence from Lord FITZMAURICE. After taking evidence on Thursday, the Committee considered their future procedure during the absence of the chairman at the Hague Conference.

GOOD PRICE FOR COX'S ORANGE PIPPIN APPLE.—Mr. B. G. VAN HEYST, Wyk, a Dutch correspondent, sends us from Holland a cutting from an American publication, *American Fruits*, in which it is said that "The Cox Orange Pippin, an Apple of English origin, sells regularly on the British market at one shilling or 24 cents each. It can be grown successfully in this country." It is a well-known fact that good fruits of this incomparable variety always sell well here, but we are afraid that cultivators have to be content with about one-third of the price stated, although in late winter, in particular seasons, it is possible that samples have been sold at 6d. each, or even more.

ARRANGEMENTS FOR THE CONGRESS OF GERMAN ROSARIANS.—A congress will be opened at Mannheim on Sunday next, June 23, under the auspices of The Society of German Rosarians. A prize will be awarded for the best new Rose, whether shown by a German or foreign exhibitor. The lectures will include one by Prof. Dr. BEHNERS, Karlsruhe, on "Enemies of the Rose and Means for Combating Them"; one by Dr. G. KRUGER, Freiburg, on "Crossing and Hybridising the Rose, according to the most modern methods," illustrated by pictures painted from nature. The Rose exhibition will be opened on June 22.

AT "THE CITY BEAUTIFUL" CONFERENCE, to be held in Liverpool, on June 27 and 28, the following subjects will be discussed. On the morning of the 27th inst., a meeting at the Town Hall will be presided over by the LORD MAYOR, the subject for discussion being "Town and Suburban Planning." In the evening there will be an open meeting, presided over by the VICE-CHANCELLOR of the University, when the subject, "The Beautifying of our Cities," will be discussed. On the morning of the following day, Sir ROBERT HAMPSON will preside at a meeting in the Town Hall for the discussion of "Garden Cities." Prizes have been offered for the best essays written by children in the ele-

mentary schools and by pupil teachers in Liverpool on the subject of "The City Beautiful," and also for the most beautiful private house fronts and for shop and business fronts. The hon. secs. are:—The Rev. Canon MORLEY STEVENSON, Training College, Warrington; Miss HARRISON, Belmont, Storrs, Windermere; and NORMAN WYLD, Esq., The University, Liverpool; from whom all information can be obtained.

INDIA.

CLIMATIC EFFECT ON PLANTS IN THE HIMALAYAS.

No worse practice could be indulged in than the summer pruning of fruit trees here in the Himalayas; it has been tried, and there ensued a regular thicket of undesirable shoots. As further illustrating the vast difference climate makes, I may mention that some years ago I resolved to lift some 900 fruit trees, ranging from three to five years of age, owing to their unprofitableness. They were all grafted on seedling Apple and Pear stocks. The operation was performed in our monsoon—July and August, every tree being taken quite out of the ground, severely root pruned, and put back in the same place. The operation was quite successful, the plants recovered rapidly, made new roots, and by the ensuing spring-time very little check was noticeable. Since that time many fruit trees have been lifted and root pruned in July and August with perfect success.

SCARLET RUNNER BEANS.

This vegetable often becomes a perennial here, and forms very large roots and underground stems something like a Globe Artichoke.

DAHLIAS.

Cuttings of this plant, if dibbled in the soil out-of-doors in the month of July, make roots easily, but the curious point is that the tubers without exception run very long. In no case have I been able to get tubers at all like imported ones; they all become long and of torpedo shape. Old tubers, when three years old, can only be described as monstrous, as they measure some feet in length.

CHRYSANTHEMUMS.

A considerable modification ensues with rapidity even in imported plants. It is with difficulty ordinary cuttings can be got to make roots in this country, but cuttings having attached to them underground rhizomatous-like stems will root freely. This is exactly the form the plants assume; what eventually become shoots have all a rhizomatous underground stem, all of which root freely up to the ground surface, and also in some sorts travel a considerable distance. Practically all plants sold in this country are pieces detached from the parent plant, and in no sense the simple cuttings known in Europe.

MIGNONETTE.

As I write I see before me a small plot of Mignonette, but it is derived from last year's plants, which, while apparently killed outright by the heavy winter snow, have nevertheless grown again, the roots having remained alive.

APRICOT.

The one outstanding fruit of this particular part of the Himalayas is the Apricot; it grows rapidly, forms handsome trees very quickly, fruits enormously, and is the one fruit that never by any chance fails to crop. The fruits ripen for the most part in grand weather before the advent of monsoon. I think this fruit could be sent to Covent Garden Market with advantage to the producer at 15 rupees per maund—that is to say, one pound sterling per maund of 80 lb., say threepence per lb.—wholesale, of course. But, owing to the nature of this fruit, I fear it is quite impracticable, for it would have to be sent a distance of 1,400 miles by railway across the great plain of India down to Bombay, and in May this plain is indescribably hot and dry. F. W. Seers, Naini Tal, India.

ODONTOGLOSSUM CRISPUM HEATONENSE.

THE illustration at fig. 167 represents a flower of a very fine blotched variety of *Odontoglossum crispum* raised by Messrs. CHARLESWORTH & Co., Heaton, Bradford, and which was exhibited by them together with others of the batch at the Temple Show on May 28. The flower is white, with a shade of purple showing from the back to the surface. The larger blotches are reddish purple in colour, and the smaller ones dark-rose colour. A fault of many of the home-raised varieties of *O. crispum* obtained from spotted forms, is that in the progeny the colours are often diffused and not distinctly displayed. In this form and others of the Heatonense class the blotching is clear and resembles that of the imported varieties.

may be put down at about £5 per acre, as the following figures from various parts of the British Isles will show:—

ENGLAND AND WALES.—Kent, cost of planting, £8 3s. per acre; Yorkshire, cost of planting and fencing, £4 18s. 9d.; Carnarvonshire, for planting and fencing, £5 2s.

SCOTLAND.—Perthshire, 3,665 acres (planting), £2 10s. per acre; Ross-shire, 3,950 acres (planting), £2 10s.; Inverness-shire, 1,295 acres (planting and fencing), £3 10s.

IRELAND.—Co. Wicklow, 700 acres, £4 13s. 11d.

In connection with these figures, it may be assuring to state that in each case the cost of forming the plantation was carefully noted, and the figures given are strictly correct. The cost of fencing and drainage will often make a dif-

per annum. It may be well to remember, too, that all the above-named plantations were formed on bleak, exposed moorlands—the very class of waste lands that are so strongly advocated as the woodlands of the future, and, therefore, the cost of planting may be considered as identical, in both cases about £5 per acre.

This, with £2 5s. for cost of purchase, and 5s. for incidentals, would bring the initial total expenditure to £7 10s. per acre. In my previous article I suggested that altogether 1,000,000 acres should be planted over a period of 25 years, at the rate of 40,000 acres per year, the cost of which would be, roughly, £300,000—a comparatively small sum, it must be admitted, when compared with the £25,000,000 annually expended by this country on supplies brought from abroad.

FINANCIAL RETURNS FROM AFFORESTING WASTE LANDS.

There is ample evidence that land will yield not less than £1 per acre annually for 50 years under a crop of timber, and many instances can be recorded where the standing crop after half a century realised from £50 to £75 per acre. The extensive plantations formed by the late keen arboriculturist, Lord Powerscourt, near Dublin, by the Duke of Athol, of Dunkeld, and Blair-Athol, in Ross-shire, Inverness-shire, but particularly in Aberdeenshire—all of which were formed from 35 years to fully 75 years ago, and the cost of planting carefully noted—are surely sufficient evidence not only of the feasibility of afforesting waste mountain lands, but of the profits which have attended the undertakings, not to speak of the incalculable benefits that have been secured in the way of shelter to the dreary, treeless wastes and the bleak, exposed uplands where the planting was carried out.

Mr. Lewis Miller, of Benachie, Perthshire, tells me that between the years 1870-90 he cut down in Scotland growing timber to the value of over £250,000, and his unique experience with native woods during the past 30 years, and on the basis of prices ruling during that time, justified him in saying that growing Larch, Scotch Fir, and Spruce would give to a proprietor from the time it was planted an average of £1 per acre per annum, apart from the cost of planting. A great many of the plantations he had cut down in Scotland were about 50 years of age, and yielded over £50 per acre, apart from the value of the thinnings taken out of them previous to the time they were finally cut down. To one proprietor in Aberdeenshire he paid over £80,000 for plantations about 50 years of age, and the price on an average worked out at more than £50 per acre. One plantation of Larch in Aberdeenshire, about 70 years of age, yielded £150 per acre; another plantation, all Larch, about 44 years of age, gave over £100 per acre, and these plantations were for the most part grown on pasture or waste land.

Mr. Miller also added that there were millions of acres of pasture land in Scotland, which at present only yielded the proprietors a rental of a few shillings per acre, and which, if planted to a height of 1,500 feet above sea-level, would give them not less than £1 per acre per annum on the average. As far as actual profit is concerned, it will be prudent to assume that for the first 20 years no return whatever will be derived from hillside plantations, the thinnings up to that time doing little more than covering the expense of felling and interest on first cost. For 25 to 35 years an annual return of fully 12s. per acre has been forthcoming, whilst the value of the standing crop at the latter age has been found to be from £50 to £60 per acre. Generally speaking, I do not think that these figures would be too high, as on the estate of Balfour, in Scotland, the Larch on a hillside of 45 years' growth were valued at 20s. each, while a similar valuation was made of the individual trees on two well-known estates in North Wales at the age of 40 years.

FIG. 167.—ODONTOGLOSSUM CRISPUM HEATONENSE: FLOWER WHITE, WITH PURPLE AND ROSE BLOTCHES.

FORESTRY.

OUR FUTURE TIMBER SUPPLIES.

IN a previous paper (see *Gardeners' Chronicle*, December 15, 1906, p. 401) under this heading I gave a rough outline of the principal timber supplies of the world, with special reference to our own requirements as by far the largest consumers, and at the same time I pointed out the pressing necessity for planting up some of the waste lands of this country as an asset for the future.

The cost of forming plantations would vary greatly with the nature of the soil, whether fencing and drainage are necessary, and the cost of labour in the particular district where planting is to be engaged in.

For all practical purposes, however, the cost

ference of quite £2 per acre, but, where neither has to be engaged in, I have known the work to be carried out at less than £3 per acre. It is somewhat difficult, however, to arrive at an average as to the cost, the difference between notch and pit planting being considerable, as is also the rate of wages paid in different parts of the country. In Scotland especially, what is termed "notch" planting is that generally adopted on rough, exposed, and rocky ground, and the plantations so formed will not cost much more than one-half of such as were pitted. With "notch" planting much smaller, and, consequently, less expensive, plants are used.

The Ross-shire plantations referred to above formed a bleak and barren moorland, which the crofters, who used it as a common for their cattle and sheep, refused to rent at 1s. per acre

The price paid, too, by Mr. Miller for Larch plantations in Scotland, from 40 to 60 years' growth, was never less than £80 per acre. From all these figures it is reasonable to assume that land under plantations yields not less than £1 of rent annually from the time of planting onwards for, say, 60 years, at which date the crop will be ripe for felling, especially Larch, which is the tree above all others for afforesting the waste and mountain lands of Scotland and Wales at least.

After careful computation I have found that the waste lands referred to in this paper were rented at an average price of 2s. 8d. per acre, and when this is compared with the 20s. per acre now returned under a crop of timber, besides the interest on the money originally expended, the value of the lands will be found to have increased about sevenfold.

The profits of timber culture on the Continent would appear to be about on a par with those returned in this country, as Dr. Schlich has told me of some of the German woodlands, and Professor Fisher, in writing to me, said that the woods on the Vosges Mountains pay annually £2 per acre after all expenses have been deducted; while in Belgium the returns are about similar. The Saxon State forests he also mentions as having returned 21s. per acre of net profit during 1903. A. D. Webster.

NOTICES OF BOOKS.

ALPHABET OF GARDENING (ILLUSTRATED).*

This book, as the author tells, is a primer for amateur and professional gardeners, also for the use of students in horticulture. It deals with plant life, soils, manures, plant propagation, hybridising, and the elementary principles of practical and scientific gardening. We may say at once that when the reader has read and digested this *Alphabet of Gardening*, and supplemented the knowledge thus gained by some years of work in a garden under an efficient gardener, he may make his way in the pursuit of gardening. As of necessity in a work so small and cheap, the matter, though trustworthy and accurate, is much condensed. The author has, therefore, afforded the reader a few names, where he has considered it to be needed, of authors whose more elaborate works will prove of much service to him in his work and enable him to gain a knowledge of the how (art) and why (science) of every matter connected with the life and cultivation of plants, and the soils in which the latter are grown. The work contains many illustrations of the various methods of seed sowing, grafting, layering, budding, dis-budding, planting, transplanting, hybridising, and many other operations, all of which will be found useful in assisting the reader to understand the text, which necessarily contains many technical terms.

COLONIAL NOTES.

TOBACCO IN JAMAICA.

The following reference is made to the cultivation of tobacco in Jamaica in the *World's Commercial Products*:—In Jamaica the cultivation of tobacco has lately received much attention. The soil, climate, and general conditions are favourable in many parts of the island, and the area at present under tobacco is about 400 acres. The tobacco trade has progressed satisfactorily during the past 11 years. Jamaica cigars and cigarettes, which are manufactured at Kingston, have gained an enviable reputation in the market, and the industry may now be considered to be well established. In the opinion of many experts, Jamaica cigars are the finest produced in the British Empire. The exports in 1904-5 were valued at

£22,408, as compared with a value of £19,567 in the preceding year, and these figures are exclusive of the locally-grown tobacco consumed in the island.

BRITISH GUIANA.

The exports of Rice from British Guiana, during the year ended March 31 last, amounted to 3,474,512 lbs., valued at 89,078 dols., the corresponding figures for the previous year being 29,728 lbs. and 718 dols. (Demerara *Argosy*.)

A GRENADA MOUNTAIN ESTATE.

DURING the month of January, I accepted the temporary charge of a large estate in this island.

At the time of my stay there, January 21 to March 31, it was the dry season. My regular home is situated near to the sea at St. George's, the capital of the colony, where the effects of the dry weather are immediately felt after the wet season, and Cocoa and other deciduous trees become bare for weeks together. The grass turns brown, fodder is scarce and expensive, and the heat relatively intense. But in my new home, with refreshing mountain streams, shaded valleys, and a deliciously cool atmosphere, the conditions during the dry season are quite the contrary. The trees when the Cocoa crop was gathered were green with their leafage, fodder was plentiful, and Bananas, Plantains, Bread Fruit, the Bread Nut, and many other tropical fruits and food-producing plants were giving plentiful returns. And yet this estate is situated only four to seven miles away from St. George's. Large crayfish were plentiful in the streams.

On the slopes and mountain ridges monkeys roamed in troops in search of fruits. Along the streams the white and blue gaulins, or herons, were occasionally seen flying, or, it may be, were settled in some tree or upon a favourite boulder. Many interesting Orchids, both terrestrial and epiphytal, were seen, also majestic and low-growing Ferns, Mosses, and a host of other interesting plants. The following trees may be mentioned as standing out especially prominent among their fellows in the mountains: *Mimusops globosa* (the bullet-wood), the largest and most valuable of all our timber trees, and *Dacryodes hexandra* (the mountain Gommier), from which a white and fragrant gum is obtained. Woodsmen value this tree and make use of it to light fires at a time when the air is charged with moisture. As an incense it is also utilised in the local Roman Catholic churches. The bole of the tree is used for making "dug-outs," or rough canoes, and the wood when cut up is utilised for roofing houses; *Prestoea trinitensis* (the mountain Cabbage), is a large gregarious Palm. The heart or growing point at the apex of the tree sometimes forms one of the ingredients of our home-made pickles.

Monkeys I found very troublesome. They often destroyed scores of Cocoa pods early in the morning or later in the afternoon after the men had ceased work for the day. One can always tell whether the pods have been bitten by rats or by monkeys. Monkeys bite off the tip of the pod, whereas a rat usually makes a hole on the side. Many fine, well-formed fruits, just ready for picking, are rendered useless by these animals. The seeds are extracted and the acid-flavoured material which covers the seeds is sucked off and then the seed is allowed to fall to the ground. The rat, I believe, eats the seeds. Where these two animals abound no one but those who have direct dealings with a Cocoa estate, situated as this one is, could know of the serious loss the proprietor undergoes from this cause. Of course, the losses can be minimised by employing poisons, or by the aid of traps and guns. Wood ants were another pest, but doses of calomel placed in their nest readily destroyed them.

Under cultivation I found, besides Cocoa and Nutmegs, large plantations of the *Castilloa* rubber tree, some having been planted as tiny seedlings at the end of the preceding year, others had become

fine healthy trees almost fit for bleeding. The Nutmegs were free from insect or vegetable pests, excepting an occasional wood ant's nest, but the Rubber and Cocoa trees did not escape attack. A fungus was working mischief at the base of the Rubber trees, killing them eventually, whilst destructive beetles and black blight were also doing much mischief.

The Cocoa tree was a prey to numberless epiphytes, parasites, and the obnoxious and destructive Cocoa beetle, whose boring grub is a source of continual annoyance. On some estates gangs of boys are engaged to collect the mature insects.

Phthirusa (Loranthus) pyrifolia, known locally as Captain Bois, furnished an unwelcome parasite. This had to be vigilantly sought for and removed, otherwise the trees would be so injured that little or no crops could be expected, as whole branches would be killed outright by the roots of this plant.

The following plants, in alphabetical order, I also found in more or less abundance upon the Cocoa trees apart from the Captain Bois. These were:—

Anthurium Hookeri, Kunth.—common.
Columnnea Scandens, L.—frequently met with.
Caragata lingulata, Lindl.—plentiful.
Catopsis nitida, Baker—found occasionally.
Dichaea muricata, Lindl.—scarce.
Epidendrum elongatum, Jacq.—plentiful.
E. globosum, Sw.—a destructive pest to the trunks of Cocoa trees.
E. difforme, Jacq.—rarely seen.
E. fragrans, Sw.—very plentiful.
E. nocturnum, L.—common.
E. anceps, Sw.—common.
E. ramosum, Jacq.—very plentiful.
E. rigidum, Jacq.—rarely seen.
E. strobiliferum, Rchb. f.—not common.
Gymnogramme elongata, Hook.—not common on the Cocoa.
Hymenophyllum polyanthos, Sw.—seldom observed on Cocoa.
Macromitrium brevipes, C. Müll.—a Moss pest.
Neckera undulata—a lovely little Moss found in the

more shaded parts of Cocoa fields upon the tree trunks.
Ornithidium coccineum, Salisb.—plentiful.
O. confertum, Griseb.—a veritable plague on the Cocoa branches.
Pleurothallis pruinosa, Lindl.—I regard this among the worst of all the epiphytes, as it is difficult to clean off the trunks and branches if the trees are in the least dry condition.
Polystachya luteola, Hook.—met with occasionally.
P. foliosa, Rchb. f.—seen here and there.
Polypodium pectinatum, L.—common.
P. piloselloides, L.—a most obnoxious plant upon the Cocoa, owing to its numbers and to the long rhizomes covering the trunks and branches.
P. repens, L.—plentiful.
Peperomia nummulariaefolia, exceedingly plentiful.
Trichomanes Kraussii, common.
Tanitis angustifolia, R. Br.—great quantities observed.

—W. E. Broadway, *The Plant and Seed Nurseries, Grenada, W.I.*

THE HARDY FLOWER BORDER.

PENTSTEMON GLABER.

THE advantage of having free-flowering perennials, normally short-lived, with which to make good the blanks that occur in plant borders after the earlier bulbs have passed their best, will appeal to every gardener. There are many plants that can be reared in a reserve garden that will serve this purpose admirably, and of those that flower well at this season the "Smooth Snake's Head," *Pentstemon glaber*, is a good type. A sowing of new season's seed in August, or the cuttings formed on old plants that have been cut back to induce them to break freely, if inserted in a cold frame, will provide excellent plants for the following season's display, and they may be allowed to remain in the nursery quarters till within six weeks of the time they are due to flower if the soil is retentive and strong. Of the typical *P. glaber* there is not so much to describe as of its varieties *Brandegii* and *roseus*. *Brandegii* has flowers of rich amethystine blue, and practically every plant is a cluster of one-sided spikes, so densely flowered that individual blooms are often misshapen, but they produce an excellent colour effect. If the exhausted spikes are cut away as they become shabby, relays of new ones appear and carry the display over a period of two months, almost without intermission. *Roseus* is of very attractive colouring. It

* By T. W. Sanders, F.L.S. Published by W. H. & L. Collingridge, 148 and 149, Aldersgate Street, E.C. Price 1s. 6d. net.

is deep pink, touched with rose on the outside of the tubes, and it is equally as floriferous as Brandegii. In cold and wet soils it will be found an advantage to keep the stock young by frequent propagation. Although really perennial and capable of living five to six years without deterioration, as I have been able to prove, the plants often flower and produce seed so freely that they live for only two years.

EREMURUS TUBERGENII.

ONE of the latest hybrid Eremuri is Tubergen's variety, a cross between *E. himalaicus* and *E. Bungei*, and a very attractive and handsome plant it is. The root-stock is slender, like *E. himalaicus*, the leaves form a neat funnel of glaucous green that never appear untidy, and which maintains its shapeliness until the leaves wither. They are prac-

are surprisingly easy to intercross. If I may suggest a species for use as a parent when much that has been done in so good, it would be that *E. Olgæ* be more freely used. There is a grace of spike in this species that will ensure freedom from stumpy spikes in its offspring, and its rapid increase by crown division is another desirable factor.

E. TUBERGENI is a beautiful plant, unique in colour and pleasing in its compact habit. It cannot fail to attract, and, so far as my experience shows, is not in any respect difficult to grow. It flowers with the last of the *E. robustus*, three weeks later than *E. himalaicus*. *G. B. M.*

FIR GRANGE, WEYBRIDGE.

IN our issue for March 30 last a note was published on p. 211 which described the spring flowers that were just commencing to bloom

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

HARDY GUNNERAS.—In February, 1902, I found a species of *Gunnera* growing among stunted Beech trees, on a thin stratum of stony debris, which had fallen from the cliffs above on to the ice, near the foot of a glacier descending from the great mountain known as the Tronador, in the main range of the Andes of Chile in latitude 41. The fruit was then ripe, and I succeeded in raising plants from it on my return home. When young they seemed impatient of spring frost, and having no living plants of *G. scabra* or *G. manicata* with which to compare them, I was doubtful as to whether this variety could be looked upon as hardier than those species. Mr. A. C. Bartlett, however, now writes me from Pencarrow, Cornwall, saying that the plants have proved to be much hardier than

FIG. 168.—FIR GRANGE, WEYBRIDGE, THE RESIDENCE OF W. A. BILNEY, ESQ.

(Photo by J. Gregory.)

tically those of *E. Bungei*, much broadened and more rigid. The spike is also a model of neatness. It measures 5 feet in length, and about 2 feet of this is occupied by the inflorescence. The flowers are coloured a pretty shade of chrome yellow, a little stronger than that seen in *Chrysanthemum Mrs. Mease*, but the soft shading is there nevertheless. The habit of the spike is that of a shortened, many-flowered *E. himalaicus*, and the flowers are of the size and shape of *E. Bungei*. With such plants as *Tubergeni*, *Warei*, *Mrs. Reuthe*, *Shelford*, and others available as material to start with, one may expect a host of hybrid Eremuri in the near future. They

freely in the gardens at Fir Grange, Weybridge, the residence of W. A. Bilney, Esq. Since the note was published, Mr. Gregory has photographed the ground rockery near to the dwelling house, this being reproduced at fig. 168. Our readers will thus be able to see how interesting and attractive it is. The path over the stepping stones, between which the Thrift and other dwarf plants are growing, is one way by which the more distant parts of the garden may be reached from the house. For further notes on the Fir Grange gardens, see our issues for April 14, 1906, p. 227, and March 30, 1907, p. 198.

the species above mentioned; he says that the young leaves are not cut by the frost in spring, and that they are not so easily blackened in the autumn. Plants which I sent to Poltalloch in Argyllshire, and elsewhere have also grown well. My plant ripened seeds last year which are now germinating, and I shall be glad to send seedlings to anyone who is interested in this genus if they will ask me for them in the autumn. The plant in my garden thrives in an ordinary border on the north side of a high wall, and though it differs somewhat in appearance from *G. scabra*, yet there is so much individual variation among my plants that I do not know how to distinguish it specifically. *H. J. Elwes, Colesborne, near Cheltenham.*

CLEMATIS MONTANA.—There are few hardy climbing plants which, at this season of the year, produce such a bewildering profusion of white flowers as *Clematis montana*. Notwithstanding that the individual flowers are comparatively small, the picturesque effects afforded by its graceful hanging shoots, clothed with innumerable white flowers, more than compensate for their lack in size. A most pleasing effect may be secured with this *Clematis* when associated on the wall of the house with an *Ampelopsis*. The beautiful light-green foliage of the *Ampelopsis* will be found to admirably set off the festoons of white flowers of the *Clematis*. It is also a desirable subject for clambering over unsightly coniferous trees. This *Clematis* will succeed equally well in almost any position, and if at the time of planting it is provided with good soil it will make rapid growth. *F. G. Tutcher*.

BERBERIS BUXIFOLIA.—We should fare ill without the Barberries during the first six months in the year, for we rely on them for a constant succession of fragrant and beautiful blossoms from early January, when *B. Bealii* puts forth its crowded racemes of sulphur yellow till June, when *B. Knightii* and our native *B. vulgaris* are in beauty. Inferior to none, superior to many species, in fragrance and grace, is the box-leaved Barberry, *B. buxifolia*, which used to be called *B. dulcis*—a better name, I think, for the foliage is not very like that of a box, and the epithet *dulcis* (sweet), is peculiarly descriptive not only of the odour when in flower, but of the deliciously sweet berries, like small Grapes, which this plant ripens in abundance. The enclosed photograph [not reproduced.—Ed.] does no justice to the display of flowers, because, being yellow, they come out dark. The bush is 13 feet high and 90 feet in circumference. It was planted here about 35 years ago. *Herbert Maxwell, Monreith*.

CEREUS GRANDIFLORUS.—This gorgeous cactaceous plant is both handsome and quaint when in flower. When growing against a wall it curls and twists about like so many snakes. We have it trained along the back wall of a hip-roofed vinery, and in such a position the plants grow and flower very freely. The flowers generally begin to expand at about 6.30 p.m.; by 8.30 p.m. they are fully developed; and by 12 o'clock begin to fade. They will, however, last in a cut state for about 12 hours. Their effect is best when seen by artificial light as they grow upon the plant. When opening they appear to be all on the shiver. In cultivation they require little soil, but plenty of old mortar rubble with it. The plants should be kept moderately dry at the roots, except when they are growing quickly, at which time they need copious supplies of water, and should be syringed twice each day. If it is intended to plant this species out in a border, half the depth should be filled with crocks and potsherds, and care taken to leave no room for more soil than the roots will be likely to permeate. Propagation is easy, as in a warm temperature the plants produce roots from the stem. *W. A. Cook, Leonardslee*.

IMMATURE SEED POTATOS.—Complaint has been made with respect to the huge importations of young Potatos which at this time of year come from the Channel Islands and France, that, because so plentiful, they have been selling at the low price of 1s. 6d. per 40 lbs. That is, indeed, a small return to the growers, let the crop be ever so great, and there is a plentiful crop this season. It is odd to read also that this low figure is due to a combination of merchants and shippers, because combinations or "rings" of that description rather tend to keep prices up. However, there is the fact, whether the grower be satisfied or otherwise, that these young Potatos have been selling retail at 1d. per pound, thus bringing them within the reach of all consumers. A worse class of vegetable food than these unripe and sappy Potatos can hardly be found, for are they not our old acquaintance, the once-famous International Kidney, so beautiful as an exhibition variety, so bad when cooked? The cheapness of these immature tubers offers to all who may desire it an admirable opportunity to test next year the merits or otherwise of immature seed Potatos when planted, as against well-ripened or mature seed Potatos planted beside them at the same time and under the same conditions. Remembering that this old Kidney was raised some 40 years ago at Woodstock, by Mr. Robert Fenn, and that only two or three years

elapsed before it was put into commerce, so great a cropper was the variety, it affords evidence that some varieties at least do not readily deteriorate. Is this long life due to the inherent quality of the flesh of the variety, which is never dry, but always of a close, sappy nature, or because the tubers are generally lifted whilst they are still unripe? In any case, there is now the opportunity to obtain some of them, and, by exposing them to full light and air, induce "greening" and bud formation. By planting these tubers about the middle of July, the resulting crop should consist of tubers of similar size and of the same unripe character to lift and store in October for seed purposes. The test would not be complete, unless some roots of such Potato plants were lifted early in July, the rest being allowed to remain six weeks longer to enable the tubers to fully ripen for the purpose of planting equal quantities of both sets of tubers the following spring side by side and under precisely the same conditions. Important as is this question as to the relative value for spring planting of unripe and fully-ripe Potatos, it is feared that few are testing it. Apart from the purchasing of unripe seed tubers, growers may lift a few roots of any one or more varieties now being grown, doing so, if late ones, at the end of July, saving the tubers, and planting these, with others from the same stocks, which should be allowed to remain in the ground till October to fully ripen. *A. D.*

TRILLIUM GRANDIFLORUM.—Mr. Mallett's paper (see p. 398) on the *Trilliums* is interesting and valuable botanically, but to the ordinary amateur or gardener it does not indicate clearly

FIG. 169.—*TRILLIUM GRANDIFLORUM* FLOWERING IN SIR HERBERT MAXWELL'S GARDEN.

enough, I think, the immense superiority of *T. grandiflorum* over every other species. Except in botanical collections I do not think any other kind is worth growing. In 19 private gardens out of 20 what is required is a guide to selection, not an aid to collection. The multitude to choose from is so bewildering that the chief difficulty consists in growing the best species, and excluding or rejecting those of inferior beauty. Having plenty of *T. grandiflorum*, both in the garden and in the woods, I do not care to cultivate any other species. I enclose a photograph (see fig. 169) of this beautiful plant in full bloom. *Herbert Maxwell, Monreith*.

EARLY ROSES.—The season has been a good one for early Roses. In the absence of much brilliant sunshine the flowers have maintained better and brighter colours. *Rosa sericea* has been grand, and if cut off in large branches it is most beautiful. *Rosa xanthina* has been brilliant. *Mme. Capucine*, of a shade of coppery-scarlet, excited much admiration. *Rosa rugosa*, "Blanche Coubert," a semi-double variety, with large, snowy-white flowers, is handsome, whether growing in masses or as isolated clumps. It flowers all the summer, is beautifully fragrant, and very suitable for the furnishing of vases. The white and yellow varieties of the Banksian Rose have been grand, and they are useful for the decoration of tables. *W. A. Richardson* and *Marechal Niel* are still very effective. These produce flowers of better quality when growing on their own roots; they are much deeper in colour, and are produced over a much longer period. The *Bride*, *Sunset*, *Anna Olivier*, &c., have all given fine flowers. *W. A. Cook, Leonardslee, Horsham*.

SOCIETIES.

ROYAL HORTICULTURAL Scientific Committee.

JUNE 11.—*Present*: Sir J. T. D. Llewelyn, Bart. (in the chair); Dr. M. C. Cooke, Lieut.-Col. D. Prain, Prof. G. Boulger, Rev. W. Wilks, Messrs. J. T. Bennett-Poë, J. Douglas, A. W. Sutton, G. S. Saunders, G. Massee, C. T. Drury, F. J. Baker, G. Gordon, A. Worsley, W. C. Worsdell, E. M. Holmes, H. T. Güssow, and F. J. Chittenden (hon. sec.).

The late Dr. M. T. Masters, F.R.S.—The chairman, Sir J. T. D. LLEWELYN, after referring in sympathetic terms to the loss the Committee had sustained in the death of Dr. MASTERS, who had for so long presided over the deliberations of the Committee, a loss which would be felt not only by them, but by the whole Society, and by the whole horticultural world, moved that a letter of condolence should be sent to his family. Dr. COOKE seconded the motion, and it was carried by all the members of the Committee upstanding in their places.

Genetics.—Mr. CHITTENDEN reported that he had received a communication from Mr. BATESON concerning the proposed meetings for the special consideration of the progress in the study of genetics, brought forward at a recent meeting by Mr. A. WORSLEY. Mr. BATESON expressed himself in sympathy with the scheme. Mr. CHITTENDEN also announced that Mr. BIFFEN would, at the next meeting, show a series of hybrid Sweet Peas to illustrate the Mendelian laws of inheritance.

British plants.—Mr. DRURY showed some plants of *Senecio squalidus*, collected by Mr. C. B. GREEN, of Acton, on the railway bank near Southall, Middlesex. Mr. WORSDELL said he had found it near the same place. The same gentleman sent the *Orchids*, *Acera anthropophora*, *Orchis Morio*, *Habenaria conopsea*, and *Orchis maculata*, collected near Harefield, in Middlesex.

Fern distribution.—Mr. DRURY also showed, on behalf of Mr. A. DEAN, a Fern, *Adiantum Capillus-Veneris*, enclosed in a bottle, one of many others growing in similar situations (but not all of the same species). A newly-formed garden in Surbiton was edged with these bottles forced neck downwards into the soil, and the spores from which the Ferns had grown must have been present in the soil. As Mr. DRURY remarked, this illustrated well the ubiquity of the spores of Ferns.

Fruit of Carum nigrum, Royle.—Mr. E. M. HOLMES showed the fruit of this Indian plant. The fruit possesses a distinct odour of Cummin.

Spurless Aquilegia.—Mr. EMPSON, of North Walsham, sent flowers of a seedling *Aquilegia* which possessed no spurs. The form is not at all uncommon.

Injured Pistacchio Nuts.—CECIL WHITAKER, Esq., sent a number of *Pistacchio Nuts*, grown in Sicily, which had been rendered completely useless owing to the attacks of some insects.

Malformation of Miltonia vexillaria.—Baron SCHRODER sent a curious spike of this Orchid, which bore four apparently double flowers. The spike was produced on a small and not very vigorous plant, taken from a larger plant, which had previously borne only single flowers of the ordinary type.

Spirally-twisted Cedar.—Mr. CHITTENDEN showed photographs and shoots from a Cedar (*Cedrus atlantica*), the trunk and branches of which appeared to be spirally twisted, so that a corkscrew-like groove ran down them. Many of the young shoots upon the tree showed the same curious character. The tree is growing in the garden of Miss SEABROOK, Springfield, Chelmsford, and appears to be unique.

Ribes sanguineum double.—Mr. WORSDELL reported that he had examined the double *Ribes* shown at the last meeting by Sir E. LODGE, and found that each "flower" was not only doubled, but was, at the same time, of a compound structure, representing a rudimentary phase of splitting up into a number of flowers. No fungi or insects could be found in the flowers or twigs, although one or other of these may have occurred at an early stage in the plant's growth. A plant bearing similar flowers occurs at Kew.

LINNEAN SOCIETY.

JUNE 6.—At a general meeting held on the above date, Prof. W. A. Herdman, F.R.S., President, was in the chair.

The President invited Dr. W. Carruthers, F.R.S., the representative of the Society at the recent Linnean celebrations in Sweden, to make a report, upon which Dr. Carruthers gave an account of the proceedings (see our issue for June 1, p. 349).

The General Secretary added a few supplementary remarks, pointing out on a map on the screen the position of the places named, and then showing lantern slides of Lund University, the obelisk at Rashult, the Cathedral at Upsala (three views), and a students' procession in front of Upsala University.

Mr. G. C. DRUCE, F.L.S., showed a specimen of *Orobancha Ritro* from the Channel Islands, which had been named var. *hypochæroides* by Günther von Beck; also fresh specimens of *Bromus interruptus* from N.W. Northants, and *Orchis Simia*, gathered the previous day.

Mr. G. GLOVER exhibited a small portrait of William Kirby, the entomologist, painted on Academy board. The Rev. T. R. R. STEBBING recalled the early history of the celebrated "Introduction to Entomology" from the pens of Kirby and Spence.

JUNE 7.—The President and Council held a reception in the rooms of the Society, in honour of the 200th anniversary of the birth of Linnæus on May 13/23, 1707. Nearly three hundred guests were present, almost one-half being ladies, amongst the guests being His Excellency Count Wrangel, the Swedish Minister, and other members of the Legation, and several Swedish visitors. A special feature of the exhibition was a display of manuscripts, books, personal relics, medals, &c., of the great Swedish naturalist, which belong to the Society, and the beautiful Inlander medallion was surrounded by a wreath of laurel, whilst the Swedish flag formed a background to the small model of Kjellberg's statue, in the library. During the evening Mrs. D. H. SCOTT exhibited her animated photographs of the growth and movements of plants. In the meeting room a series of short lectures was given:—(1) By Prof. POULTON, on "Burchell's Travels and Discoveries"; (2) Prof. HERDMAN, on "Ceylon Pearl Fisheries," prefacing his remarks by a short discourse on Linnæus and the recent celebrations in Sweden, "it being understood that all that we do, and our very presence here this evening is in honour of Linnæus and in commemoration of the foundations he laid in the science we love"; (3) Lieut.-Colonel PRAIN, "The General Interest of Economic Studies"; and (4) Mr. F. J. LEWIS, on "The Plant Remains in British Peat Mosses." These lectures were timed to extend from 9 to 10.45; the conversation closing at 11 o'clock.

BIRMINGHAM BOTANICAL AND HORTICULTURAL.

JUNE 12.—Two extra flower shows were held by this society last summer, and in March this year it was decided to repeat the experiment during the present season. The first of these was held on the above date, the second one being arranged for July 3. The display on the 12th inst. was an excellent one, Orchids being exceedingly well shown by both amateur and trade growers.

Three First-Class Certificates, two Awards of Merit, and one Cultural Commendation were awarded to individual plants—all Orchids.

ORCHIDS.

The Rt. Hon. JOSEPH CHAMBERLAIN, M.P., Highbury, Birmingham (gr. Mr. J. Mackay), sent a beautifully-arranged group in which were some finely-grown and well-flowered varieties of *Cattleya Mossiæ* and *Miltonia vexillaria*. Arranged with these were good plants of *Lælio-Cattleya Canhamiana*, with large, shapely flowers; *L.-C. Aphrodite*, also *Thunia Bensoniæ*, *Phalænopsis Rimestadtiana* and *Odonotoglossums*. (Silver-Gilt Medal.)

W. W. BUTLER, Esq., Norfolk Road, Edgbaston (gr. Mr. R. Jones), showed an extensive and interesting collection containing excellent specimens of *Lælio-Cattleya Martinettii*, *L.-C. Fascinator* Princess Maud, and *L.-C. Dulcis*;

also *Lælias*, *Phalænopsis Rimestadtiana*, *Trichopilia Wagneri*, *Thunia Winniana*, *Phaius hybrida*, a good selection of *Cattleyas*, and a few very fine *Odonotoglossums*. (Silver-Gilt Medal.)

Messrs. HUGH LOW & CO., Bush Hill Park, Enfield, contributed a bright group of large, well-flowered varieties of *Cattleya Mossiæ* and *C. Mendelii*. (Silver Medal.)

Messrs. JAMES CYPHER & SONS, Queen's Road, Cheltenham, sent a group in which were many plants of botanical interest. *Lælio-Cattleyas*, *Odonotoglossums* and *Miltonias* formed the principal features of this very instructive group. *Epiphronitis Veitchii*, *Cirrhopetalum Cumingii*, *Masdevallia muscosa* and *Trichopilia marginata* were also noted. (Silver Medal.)

Messrs. A. J. KEELING & SONS, Westgate Hill, Bradford, staged a group consisting principally of *Cattleyas*, *Lælio-Cattleyas* and *Cypripediums*. (Bronze Medal.)

MISCELLANEOUS FLOWERS.

Messrs. JAMES RANDALL & SONS, Shirley, Birmingham, had a splendid lot of flowers of American Carnations and Sweet Peas. (Silver Medal.)

HUGH MITCHELL, Esq., Augustus Road, Edgbaston (gr. Mr. J. Batchelor), displayed a large number of varieties of Pansies on the old-fashioned "show" boards. (Vote of Thanks.)

Mr. ROBERT SYDENHAM, Tenby Street, Birmingham, contributed a pleasing assortment of Sweet Peas, Spanish Irises and Iceland Poppies.

From E. MARTINEAU, Esq., West Hill, Edgbaston (gr. Mr. O. Brasier), came a batch of *Schizanthus* plants bearing a profusion of delicately-coloured flowers. Also forced hardy shrubs and Mignonette. (Bronze Medal.)

Messrs. RICHARD SMITH & CO., Worcester, sent hardy flowers comprising *Pæonies*, Oriental Poppies, German Irises, &c. (Vote of Thanks.)

From G. H. KENRICK, Esq., Whetstone, Edgbaston (gr. Mr. J. V. Macdonald), came a pretty group of *Miltonia vexillaria* and some remarkably well-flowered *Calceolarias*. (Bronze Medal.)

Messrs. GUNN & SONS, Olton, Birmingham, sent a collection of *Phloxes* arranged in large bunches in tall stands and jars. The most effective varieties were Lady Napier (white), Le Soleil (pink), and Perfection (white, with purple centre). (Bronze Medal.)

FIRST-CLASS CERTIFICATE.

Cattleya Mossiæ Queen of Denmark, from Messrs. HUGH LOW & CO., Enfield. A very pleasing variety, with large, pale, purple sepals and petals; the lip is orange-yellow-coloured and beautifully frilled; throat brown, streaked with purple.

Brasso-Cattleya Thorntonii (*Brassia Digbyana* × *Cattleya Gaskelliana*), from Rt. Hon. JOSEPH CHAMBERLAIN, M.P. The plant exhibited carried large, well-formed, light purple flowers with a broad, deeply-frilled lip. The throat is stained with deeper purple and blotched with yellow.

Lælio-Cattleya Martinettii flavescentis, from Messrs. JAS. CYPHER & SONS. A shapely, fawn-coloured flower with a rich purple lip beautifully fringed.

Odonotoglossum percutum, from Messrs. JAS. CYPHER & SONS, Cheltenham. Medium-sized flowers, white, heavily spotted with purple, and marked with yellow on the lip.

A Cultural Commendation was awarded to Mr. J. MACKAY (gr. to Rt. Hon. JOSEPH CHAMBERLAIN, M.P., Highbury), for *Cattleya Mossiæ* growing in a small pot and carrying twenty large flowers.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

JUNE 13.—Committee present: Messrs. E. Ashworth (Chairman); A. Warburton (Vice-Chairman); J. Cowan, Z. A. Ward, F. K. Sander, W. Stevens, A. J. Keeling, J. Cypher, F. W. Ashton, P. Smith, C. Parker, and P. Weathers (Hon. Sec.).

A. WARBURTON, Esq., Haslingden, staged a fine group in which were many choice forms of *Odonotoglossums*, including both hybrids and

species. One of the most remarkable was *O. × ardentissimum* var. *Robsonæ*, a very distinct flower with well-defined markings and a larger area of white than in most forms: the plant was given a First-Class Certificate. A good form of *Cattleya Mossiæ* named "Queen of Denmark" gained an Award of Merit. There were also some good forms of *Miltonia vexillaria*. (Silver-Gilt Medal.)

J. LEEMANN, Esq., Heaton Mersey, exhibited a fine group of plants which included several beautiful *Lælio-Cattleya* hybrids, and a number of choice albino forms of *Cattleya Mossiæ*, the latter being particularly well cultivated. (Silver-Gilt Medal.)

Mr. W. BOLTON, Wilderspool, Warrington, exhibited a magnificent group of *Miltonia vexillaria*, in all about seventy plants, many of which were carrying four flower spikes. *Cattleya Mendelii* var. *compacta*, shown by the same exhibitor, received an Award of Merit. In the group were also half-a-dozen examples of *Cypripedium callosum* var. *Sanderæ*. (Silver-Gilt Medal.)

Mr. D. MCLEOD, Chorlton-cum-Hardy, obtained an Award of Merit for a distinct variety of *Cypripedium Lawrenceanum* called "McLeod's var."

Messrs. CYPHER & SONS, Cheltenham, obtained a Silver Medal for a group containing *Cattleya Mendelii*, *C. Mossiæ* in variety, and good *Odonotoglossums*. *Cypripedium* × *Mary Beatrice* var. *magnificum*, shown by this firm, was voted an Award of Merit.

W. THOMPSON, Esq., Stone, gained an Award of Merit for *Cypripedium bellatulum* var. *excellens*.

Messrs. CHARLESWORTH & CO., Bradford, exhibited a small but very choice display of plants, including varieties of *Masdevallia*, some good plants of *Phalænopsis Rimestadtiana*, *Cattleya* × *Empress Frederick*, *Promenæa citrina*, &c. (Silver Medal.) *Zygopetalum Roeblingianum* received an Award of Merit.

Messrs. HUGH LOW & CO., Enfield, Middlesex, staged a collection of good forms of *Cattleya Mendelii*.

G. W. JESSOP, Esq., Rawdon, Leeds, staged a small group of Orchids which contained *Lælias*, *Cattleyas*, some *Odonotoglossums*, and the distinct *Promenæa stapelioides*. *Dendrobium Parishii* var. *exquisitum* in this group was given an Award of Merit. (Bronze Medal.)

Mr. A. J. KEELING, Bingley, Yorks., was awarded a Bronze Medal for a small group, principally of *Cypripediums*.

Messrs. ARMSTRONG & BROWN, Tunbridge Wells, exhibited a fine specimen of *Odonotoglossum nævium*, which received an Award of Merit and a Cultural Certificate. P. W.

YORKSHIRE GALA.

JUNE 19, 20, 21.—The 49th gala and floral exhibition took place on these dates at York. The weather was unlike summer, nevertheless a large number of exhibits were brought together, and on the first day at least there promised to be a record attendance.

The show, as a whole, brought forth fine specimens of the gardener's cultural skill, but the arrangement—at least, in some of the principal and most highly-prized classes—left much to be desired. For example, a class was provided in the schedule for a number of specimen plants, and, instead of arranging the exhibits under this class together, so that comparison would be easy, some of the plants were staged amongst other classes, and in some instances they thus won other prizes. This was particularly noticed in Class 11, where three competitors were each supposed to stage "six ornamental fine foliage or variegated plants to include two *Codiaeums* (Crotons)." Instead, however, of meeting with three groups of six plants each, only one plant, a *Cycas circinalis*, appeared by itself, with the first prize card attached to it. The other plants were probably in the big groups of miscellaneous plants, in Classes 1 and 2. Such conditions should lead to disqualification, as not being in accordance with the terms of the schedule.

GROUPS OF PLANTS.

Class 1 called for a group of miscellaneous plants, in or out of bloom, arranged for effect, and to occupy an area not exceeding 300 square

feet. This was the most important class in the show, and prize money amounting to £71 was offered, attracting six competitors. The 1st prize was won by Mr. JOE S. SHARP, Valley Nurseries, Almondbury, Huddersfield. His group consisted of some well-grown examples of tall Codiaums (Crotons), Abutilons interspersed with trained pillar plants of Dorothy Perkins, Hiawatha, and Crimson Rambler Roses. The groundwork was furnished with dwarf plants such as Caladiums, Ferns, Marantas, Gloxinias, &c., while here and there were specimens of Lygodiums, Pandanus, and a small central group of Cattleya Mossiae and Phalenopsis amabilis.

The 2nd prize was awarded to J. PICKERSGILL, Esq. (gr. Mr. J. Donoghue, B.G.A.), for a bright group, in which Roses, Codiaums (Crotons), Orchids, Ferns, Kalanchoe flammea, Ixoras, Alocasias, &c., were conspicuous features. The whole was very effectively set up, and comprised a great variety of really good plants.

JAS. BLACKER, Esq., Thorpe Villas, Selby (gr. Mr. W. Curtis), secured the 3rd prize with standard Codiaums (Crotons), Rambler Roses, Lilium longiflorum, Ixoras, &c., with foils of Aralia Veitchii, Dracena Sanderiana, Pandanus Veitchii, &c. The 4th prize was won by Mr. W. A. HOLMES, West End Nurseries, Chesterfield.

Class 2 was for a similar, but smaller, group to occupy an area of not more than 200 sq. feet. There were four competitors. The 1st prize was secured by Mr. W. A. HOLMES, West End Nurseries, Chesterfield. He showed tall Codiaums (Crotons), Bamboos, and Abutilons, smaller plants on the ground being Caladiums, Ferns, Ixoras, Cineraria, &c. 2nd, Mr. J. S. SHARP, Huddersfield, who had some good examples of Dorothy Perkins Roses, interspersed with narrow-leaved Codiaums (Crotons). 3rd, Mr. W. VAUSE, 53, Warwick Street, Leamington.

A class was provided for a group of hardy herbaceous and perennial plants with pool of water, &c., to occupy space measuring not more than 30 feet by 10 feet. The 1st prize was won by Messrs. J. BACKHOUSE & SON, York, with a most artistic exhibit of rock and Alpine plants, shrubs and water plants. The effect was charming, for it was enhanced by the artistic blending of the colours, and the natural methods of showing the rocks springing out of the ground.

The 2nd prize was secured by Messrs. W. ARTINDALE & SON, Sheffield, and the 3rd prize by Mr. G. COTTAM.

Specimen plants.—The best single specimen stove plant in bloom was shown by Mr. W. VAUSE in a fine Anthurium Scherzerianum.

The class for a single specimen greenhouse plant in bloom attracted eight competitors. The 1st prize was won by Messrs. R. SIMPSON & SON, Selby, for a fine plant of Erica Cavendishii; 2nd Mr. J. W. CLARKE, Clifton, York, for a "King of Denmark" Pelagium.

Messrs. R. SIMPSON & SON also secured the 1st prize for three ornamental foliage or variegated plants, to include at least one Codiaum, and they won again in the class for three Crotons, distinct, being followed by J. BLACKER, Esq. (gr. W. Curtis).

The best single specimen plant of a Codiaum was shown by Mr. W. VAUSE.

ORCHIDS.

Valuable prizes were offered for Orchids, and seven classes were devoted to these plants. The following are the principal winners:—

The Gold Medal for the best collection of Orchids was awarded to Messrs. CHARLESWORTH & Co., Heaton, Bradford, who staged a small but good group, containing Odontoglossum ardentissimum "The Princess," O. Phoebe "Queen of Spain," O. Williamsianum, Cattleya Warneri alba, C. Whitei, and Laelia-Cattleya Phoebe.

Messrs. J. CYPHER & SONS, Cheltenham, were awarded the 1st prize for a table measuring 12 feet by 5 feet, arranged with Orchids for effect, and the same firm also won the 1st prize for 10 Orchids, a similar award for 6, and the 2nd prize for three specimens of these plants.

Messrs. MOORE, LTD., Rawdon, Leeds, were awarded the 2nd prize for a table of Orchids.

HARDY FLOWERS.

The class for hardy cut flowers produced a very fine display of colour by four competitors. The 1st prize was taken by Messrs. G. GIBSON & Co., Leeming Bar, Bedale; 2nd by Messrs. HARKNESS, Bedale; 3rd, Messrs. G. COTTAM.

Similar exhibits, but in smaller quantities, appeared in other classes.

FRUIT.

In the class for a decorated table of fruit, Lord BARNARD, Barnard Castle, Yorks. (gr. Jas. Tullett), was awarded the 1st prize, receiving 92 points out of a possible 136: Peaches, Nectarines, and Plums were well shown, and the arrangement of flowers and foliage was excellent.

The 2nd prize was won by the Earl of HARRINGTON, Elvaston Castle, Derby (gr. J. Goodacre), with 85 points; and the 3rd prize by Mr. CHAS. E. SIMPSON, York, with 80 points. There were numerous other classes for fruit.

HONORARY EXHIBITS.

The Premier Prize of five guineas to the group considered "best and most attractive in general arrangement, and most calculated to awaken the interest of visitors," was awarded to Mr. GEO. MOUNT, of Canterbury, for a display of Roses, which was universally admired.

Messrs. J. BACKHOUSE & SON displayed Liliums, Dwarf Polyantha Roses, Azalea rose-flora, Lily of the Valley, Hydrangeas, Caladiums, Begonias, Hydrangeas, Metrosideros, Euryas, &c. (Gold Medal.)

Messrs. R. WALLACE & Co., Colchester, staged a fine exhibit of hardy herbaceous Alpine and water plants. (Silver-Gilt Medal.)

Messrs. SUTTON & SONS, Reading, had a choice exhibit of various kinds of Tomatos, Melons, Cucumbers, and Peas, with a central group of hybrid Nicotianas and Rhodanthes. (Gold Medal.)

Messrs. CLIBRAN & Son, Altrincham, exhibited Pyrethrus, Carnations, Clerodendron fallax, and a new giant purple Lupinus polyphyllus.

Messrs. DOBBIE & Co., Rothesay, staged a choice collection of long-spurred Columbines, Sweet Peas, Pansies, and Violas. The same firm also exhibited samples of well-grown Potatoes.

Messrs. FEED & SON, West Norwood, occupied a considerable space with a fine collection of Caladiums. (Silver-Gilt Medal.)

Messrs. CUTBUSH & SON, Highgate, secured a Gold Medal for a large and artistic group of plants, including Metrosideros, Carnations, Rose Mrs. W. Flight, Calla Eliottiana, Verbenas, &c.

Messrs. RICHARD SMITH & Co., Worcester, had a very fine display of Golden Yews, Clematis, Pæonies, and hardy herbaceous plants. (Silver Medal.)

Messrs. R. H. BATH, LTD., Wisbech, displayed hardy herbaceous plants, tree Carnations, and Roses, with the double Lobelia Kathleen Malar. (Silver-Gilt Medal.)

Messrs. WM. ARTINDALE & SON, Nether Green, Sheffield, contributed an exhibit of tufted Pansies and Violas. (Silver Medal.)

Mr. G. PRINCE, Longworth, Berks., staged a fine display of pillar and climbing Roses in variety.

Messrs. T. S. WARE, Feltham, had a beautiful collection of tuberous Begonias and tree Carnations, the former in the most exquisite shades of colours. (Silver Medal.)

Messrs. JARMAN & Co., Chard, made a conspicuous feature of Centaureas, Iceland Poppies, Scabious, &c.

Mr. C. F. WATERS, Deanland Nursery, Balcombe, Sussex, had a fine exhibit of tree Carnations in red, cerise, pink and white, and other colours. (Silver Gilt Medal.)

Mr. C. BREADMORE, Winchester, staged a choice collection of Sweet Peas that was chiefly conspicuous for the new varieties it contained. (Silver Medal.)

Mr. MAURICE PRICHARD, Christchurch, Hants, exhibited Water Lilies and general herbaceous plants. (Silver Medal.)

A Gold Medal was awarded as a special prize to Messrs. E. P. DIXON & SON, Hull, for the best

collection of ornamental trees or shrubs and other decorative plants. These consisted of Japanese Maples, Picea "Kosteri," Standard Euonymus, Genistas, Bay Trees, and a very pretty tricoloured Beech.

Messrs. JAS. BACKHOUSE & SON were also awarded a Gold Medal for a group mainly composed of choice Conifers, Japanese Maples, Standard Buxus, Bays, Rhododendrons, and Golden Privet.

A very interesting exhibit of hybrid and cross-bred Irises, and Hemerocallis came from Mr. GEO. YELD, Clifton Cottage, York, who was awarded a Certificate of Merit. Some of the Irises were remarkably fine, especially one named "Lord of June."

THE FRUITARIAN HOSPITAL.—The Founders' Day garden party of the Lady Margaret Fruitarian Hospital will be held at Bromley on Saturday, June 23, from 4 to 7 p.m. Mr. LABHESHANKAR LAXMIDAS, who has come from India as a commission to investigate the working of the hospital with the object that similar foundations may be established in India, will give an address. Cards of invitation may be obtained from the Hon. FLORENCE COLBORN, hon. sec.

THE WEATHER.

THE FOLLOWING SUMMARY RECORD of the weather throughout the British Islands, for the week ending June 15, is furnished from the Meteorological Office:—

GENERAL OBSERVATIONS.

The weather.—The general condition was again very unsettled. More or less rain was experienced daily over a large part of the kingdom, and thunderstorms occurred some time during the period at nearly every station. They were, however, more prevalent on Sunday than on any other day.

The temperature was high at the commencement of the week, but was subsequently rather low for the time of year. Over nearly the whole of Great Britain the mean temperature for the week was above the average, but in the southern districts and in Ireland it was below the normal. The highest of the maxima—recorded at most stations on Sunday—ranged from 78° in Scotland W. and 75° in several other districts to 65° in Ireland N. The maxima were below 60° at Portland Bill during the whole period, and occasionally below that figure in some other localities. The lowest of the minima, which were registered on rather irregular dates, varied from 42° in Scotland N. to 45° in England E., and to 60° in the English Channel. In Scotland E. (at Balmoral) the lowest reading was 33°.

The mean temperature of the sea.—The water was warmer than during the preceding week at almost every station, the advance being about 2° on the north-east coast of Great Britain and nearly 6° at Margate. The actual figures ranged from 48° at Aberdeen and only slightly higher at some other north-eastern stations, to 55° at Ballyglass and Seaford, 56° at Eastbourne, and 57° at Margate.

The rainfall was largely in excess of the normal over the whole kingdom. On Sunday the fall at Tunbridge Wells and Chester amounted respectively to 1.05 in. and 1.35 in.

The bright sunshine was less than the mean except in England N.E. and E., the percentage of the possible duration ranging from 17 in Scotland W. and below 25 in the "Western Section" generally to 39 in England S., and to 41 in England E.

THE WEATHER IN WEST HERTS.

Week ending June 15.

Cold and Showery.—There have as yet been only two days during the present month which have been in any way unseasonably warm, and on the other hand only seven nights which were unseasonably cold. Four of the latter, however, occurred in the past week, and on the coldest of them the exposed thermometer fell to within 5° of the freezing point. The ground is now decidedly cold for the middle of June, the temperature at a foot deep being 2° colder, and at 1 foot deep 4° colder, than is seasonable. Since the month began rain has fallen on all but four days, but the daily amounts have been as a rule very moderate, so that the total fall only amounts to 1½ inch. Owing to the light falls of rain during the last ten days only a few drops of rain water have come each day through either percolation gauge during the week. The sun shone on an average for 5½ hours a day, which is three-quarters of an hour a day short of the June average. On one day the sun was shining brightly for over 11 hours, but on three others for altogether less than three hours. The winds have again come almost exclusively from some point between south and west, and have been, as a rule, high for the time of year. For no hour, however, did the record exceed 24 miles—direction west. The mean amount of moisture in the air at 3 p.m. exceeded a seasonable quantity for that hour by 4 per cent. E. M., Berkhamsted, June 19, 1907.

MARKETS.

COVENT GARDEN, June 19.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—Ed.]

REMARKS.—The first arrivals for the season of English Cherries, also Strawberries, from Kent have realised satisfactory prices. Plums in boxes and Black Currants in half sieve baskets have been received from France. Green Gooseberries are arriving in large quantities, but the de-

mand for them is not good, and they are not a popular fruit with the general public. Apples, as is usual during the Strawberry season, are much cheaper. Trade generally is improving. P. L., Covent Garden, Wednesday, June 19, 1907.

POTATOS.

Lincolns, 110s. to 120s.; Yorks, 110s. to 120s.; Scotch, 100s. to 110s.; Dunbars, 110s. to 120s.; Dutch (bag), 4s. to 4s. 6d.; German (bag), 4s. 6d. to 5s.; Jerseys, 7s. to 7s. 6d. per cwt.; St. Malos, 7s.; Teneriffe, 7s. to 8s. Owing to the cold weather there is still a fair demand for old Potatoes, and prices for best tubers have advanced 5s. to 10s. per ton. Trade generally is fair. W. J. C. & S., Covent Garden, June 19, 1907.

COVENT GARDEN FLOWER MARKET.

This morning (Wednesday), salesmen complained of dull trade. Good blooms of Carnation Mrs. T. W. Lawson could be purchased at 1s. per dozen late in the morning, and many flowers of Enchantress, but not the best quality ones, were sold at a very small price. Much the same conditions obtain in the case of Roses. I was offered very good blooms of Bridesmaid at 1s. per dozen; medium quality flowers of the variety Mrs. John Laing were realising 3s. per dozen on Saturday last. Many Spanish Irises are sold at prices which must be disappointing to growers. Iceland Poppies are also cheap compared with their value in former years. Oriental and Shirley Poppies are now of good quality. Lilium longiflorum does not advance in price, and many were unsold at closing time. Tuberose, Stephanotis, and Lapagerias are all well supplied. Herbaceous Pyrethrums are seen in very large quantities. Violets are not now procurable; one grower is marketing a small blue Viola as a substitute, but, unfortunately, it has no perfume. Some pretty varieties of the Cornflower (Centaurea cyanus) are seen; one of a rosy-pink shade is very pleasing.

POT PLANTS.

Supplies of most subjects are more than equal to demands, although a few things are becoming scarce. Lobelia has advanced in price, and Stocks are almost over for the season. Yellow Calceolarias are good. Both the yellow and the white Marguerites are well flowered. On Saturday I saw well-flowered Fuchsias sold in the streets at 4d. each, but this must not be taken as an indication of their ordinary market value. The same vendor was offering good Zonal Pelargoniums in 48's at 3d. each, which would cost at the lowest 4s. per dozen if they were especially ordered. Show varieties of Pelargoniums were offered by this hawk equally cheap, and he had beautiful plants in 48's at 6d. each. This class of business cripples the trade of the ordinary florist, who pays the full market prices for his plants all the year through. Rambler Roses are still very fine. Lady Gay is certainly among the best varieties, but the old Crimson Rambler is still appreciated. Hydrangeas in well-flowered plants are over-plentiful. The variety Thos. Hogg is nearly over, but H. paniculata is now very good. Lilium longiflorum has been over-plentiful. Good Petunias, both double and single-flowered varieties, are procurable. Most growers have large supplies of bedding plants on hand, but much of their stock is now "rough," especially in the case of store boxes. Best Pansies and Mimulus are now over for the season. A. H., Covent Garden, Wednesday, June 19, 1907.

DEBATING SOCIETY.

EGHAM AND DISTRICT GARDENERS'.—On Wednesday, June 8, the members of this society visited the beautiful gardens and pleasure grounds at the Dell, Egham, the residence of Baron Schröder. The members first inspected the glass houses, wherein many rare varieties of Orchids were seen in bloom. The out-of-door features gave much pleasure to the visitors, and especially remarkable was a row of Rose Papa Gontier, the plants being covered with the beautiful pink blossoms. Very gay also were the Rhododendrons. T. J. W.

SCHEDULES RECEIVED.

SOUTHAMPTON ROYAL HORTICULTURAL SOCIETY'S summer show to be held on Tuesday and Wednesday, July 2 and 3, in the County Cricket Ground, Southampton; and the annual Carnation show, to be held on the Royal Pier, Southampton, on Friday, July 26.

STOCKPORT AND DISTRICT SOCIETY'S Chrysanthemum, Flower, and Fruit Show, to be held in the Volunteer Armoury, Greek Street, Stockport, on Friday and Saturday, November 15-16, 1907.

READING AND DISTRICT ROSE SOCIETY'S fifth annual exhibition, to be held in Forbury Gardens, Reading, on Wednesday, June 26, 1907.

WINDSOR ROSE SHOW to be held on June 29, at the foot of the wooded slopes in the private grounds around Windsor Castle. The King offers a handsome Silver Challenge Cup, open to all England, for the best collection of Rose blooms.

CATALOGUE RECEIVED.

WILLIAM SYDENHAM, Bolehall, Tamworth—Carnations, Picotees, Chrysanthemums, Sundries, &c.

TRADE NOTICE.

JOHN JEFFERIES & SON, LTD.

This company has been registered with a capital of £12,000 in £10 shares (400 preference). The objects of the company are to take over the business of a nurseryman, seedsman, florist, horticulturist, farmer, &c., carried on at Cirencester, Saddington, and Somerford Keynes, all in Gloucestershire, or elsewhere, by W. J. Jefferies, as John Jefferies & Son. There will be no initial public issue. Registered Office: 1, Castle Street, Cirencester.

ANSWERS TO CORRESPONDENTS.

* * * The Editor will be glad to receive, for consideration, large photographs of horticultural subjects, suitable for forming Supplementary Illustrations to this Journal.

ADIANTUM FERN: *W. S.* The rusty leaves are not diseased, but have merely the condition of age. These old fronds should have been cut off earlier in the season. Encourage the plants to make a more liberal growth.

ARUM LILY DISEASED: *J. A.* The chocolate-coloured spot is caused by *Botrytis cinerea*, a fungus, the growth of which is favoured by excess of moisture and heat. It affected the plant before its removal from the greenhouse. We shall be pleased to have your note.

ASPARAGUS: *G. W.* The plants are attacked by a fungus—*Rhizoctinia*. Plant a new quarter with the vegetable, as far removed as possible from the diseased beds, and use plants from a healthy source. Treat the old beds with permanganate of potash, and do not carry the disease from the old to the new quarter, on your boots.

ASTER DISEASE: *F. E. S. & Co., and E. P. D. & Sons, Ltd.* The seedlings are attacked by a fungus—*Erysiphe cichoracearum*. The plants and the soil should be sprayed every five days, until the disease is checked, with a solution of permanganate of potash diluted with water to a pale rose colour.

CARNATION DISEASED: *Mack.* The plants are affected with the fungus—*Helminthosporium echinulatum*. All diseased leaves should be removed and destroyed by burning. Spraying with potassium sulphide—2 oz. to one gallon of water—checks the disease. Do not wet the foliage with water, but ventilate the structure freely in which the plants are accommodated.

CARNATION SEEDLING: *L. M.* The flower appears to possess little merit at present, but you should cultivate it for a season or more to see if it will improve; good yellow varieties of Carnations are not numerous.

CUCUMBER FAILING AT THE ROOTS: *E. R.* The plant is diseased just at the junction of root and stem. This so-called canker is caused by allowing too much water to settle about the "collar" of the plant. Apply lime or wood ashes around the lower parts of the stem.

CUCUMBER LEAVES: *J. C.* You are right in your assumption; the plants are affected with the "spot" disease. Spray the foliage with some fungicide, such as liver of sulphur dissolved in water, or a rose-red solution of permanganate of potash. It is doubtful, however, if you can arrest the disease by any treatment which would not cause injury to the plants.

CUCUMBERS: *A. B.* It is usual to stop the plant as soon as it has reached the trellis and to train the laterals thinly over the trellis. The lateral growths will need to be thinned out and pinched frequently. Read the notes that appear in these pages from time to time under "Fruits under Glass" in the "Week's Work."

CUCUMBERS CURLED: *F. J. G.* We often receive specimens such as you send. The injury is caused by some check to the growth of the plant, caused perhaps by draughts or sudden chilling of the roots by cold water. The six stamps have been placed in the R.G.O.F. box.

FERNS: *G. M.* The small Ferns have no disease present. The injury has been caused by some check, probably cold.

GOOSEBERRIES INJURED: *G. H.* There is no disease present; the damage has been caused by red spider, which has now disappeared owing to the recent wet weather.

GRAPES DISEASED: *P. J. P. and Anxious.* The injury on your berries is known as the Grape-rot, and is caused by a fungus *Gloeosporium ampelophagum*. Dredge the bunches with a mixture of one part quicklime and two parts of flowers of sulphur. The use of stable manure in the borders favours the disease.

LILY DISEASE: *G. O. P., H. E. E., W. T., G. B., and W. R.* The injury is caused by the Lily mould—*Botrytis cinerea*, a fungus disease which has been much favoured by the wet season. Spray the plants, and the surrounding ground also, with sulphide of potassium, one ounce in three gallons of water.

LINNEAN SOCIETY'S JOURNAL: *H. J. T.* Apply to the secretary of the Linnean Society, Burlington House, Piccadilly, London, W.

MAGGOTS ON BRUSSELS SPROUTS: *L. S.* The soil appears to lack lime, and there is an excess of humus present, which has caused sourness. You might try the effect of watering with lime-water. Bisulphide of carbon may be tried against the pests.

PEACH AND NECTARINE LEAVES DYING: *R. S.* The disease on your trees is known as "silver leaf," and for which, unfortunately, no cure is known. It is favoured by applying too much nitrogenous manure to the soil in which the trees are growing.

PEACHES SPLITTING: *E. R.* There is no fungus disease present to account for the trouble, which has been caused by some cultural defect—probably improper watering of the border during the resting season. See that the border is furnished with a sufficiency of lime, and if it is not, apply some old mortar rubble. We could not possibly name the variety from such imperfect specimens. Send fruits that are well developed and ripe, packed in a box with proper care, and we will endeavour to oblige you.

PEAR-FRUIT: *J. G. B.* The fruits are infested with the grubs of the Pear midge.

FIG. 170.—PROLIFEROUS ROSE.

PROLIFEROUS ROSE: *W. D. & Sons.* By no means uncommon. Many such cases have been figured in these pages, and the subject is treated of in Masters' *Vegetable Teratology*. Owing to some cause which cannot now be determined, the centre of the flower, instead of remaining arrested in its growth, lengthens into a branch.

SHAMROCK: *C. Bros.* The plant you send appears to be *Trifolium repens*. This is regarded by some authorities as the true Shamrock, but others consider *T. minus* to be the correct plant. The question is a much-debated one, and other trifoliate plants, including species of *Oxalis*, have been regarded as the true Shamrock. See Mr. Worthington G. Smith's article, published in these pages, April 7, 1900, p. 222.

TOMATO DISEASED: *S. W. W.* The plants are attacked by a fungus *Macrosporium solani*. There is no known remedy once the fruits are attacked, and the best plan is to destroy the diseased plants; thoroughly sterilise, by burning, the soil in which they were growing, and the interior of the house also by carbolic acid or some other strong fungicide. Do not grow Tomatoes in the same structure for a season or more unless unavoidable.

NAMES OF FLOWERS, FRUITS AND PLANTS.—We are anxious to oblige correspondents as far as we consistently can, but they must bear in mind that it is no part of our duty to our subscribers to name either flowers or fruits. Such work entails considerable outlay, both of time and money, and cannot be allowed to disorganise the preparations for the weekly issue, or to encroach upon time required for the conduct of the paper. Correspondents should never send more than six plants or fruits at one time: they should be very careful to pack and label them properly, to give every information as to the county the fruits are grown in, and to send ripe, or nearly ripe, specimens which show the character of the variety. By neglecting these precautions correspondents add greatly to our labour, and run the risk of delay and incorrect determinations. Correspondents not answered in one issue are requested to be so good as to consult the following numbers. **PLANTS:** *W. H. F.* *Muscari Comosum*.—*Fry's Chocolate Box*. No letter was found. 1, *Tecoma jasminoides*; 2, *Libertia formosa*.—*G. W.* 1, *Polygonum* species; 2, *Saxifraga Cymbalaria*; 3, *Saxifraga marginata*; 4, *Tradescantia virginica*; 5, *Hemerocallis flava*; 6, *Muscari Comosum*.—*J. W.* *Metrosideros floribunda*. The small Grape berries appear to be affected with a fungus disease. Send more specimens when the disease has further developed.—*K. & B.* *Juniperus virginiana*.—*G. W. R.* *Cotoneaster frigida*.—*J. R.* 1, *Tradescantia virginica*, white variety; 2, *Lychnis viscaria*; 3, *Veronica spicata*; 4, *Campanula persicifolia*; 5, *Hemerocallis flava*; 6, *Anchusa italica*.—*H. A.* 1, Send when in flower; 2 and 3, garden forms of *Helianthemum* or Rock Rose; 4, *Saxifraga* species; 5, *Aubrietia deltoidea purpurea*.—*H. H. J.* 1, *Spiraea* species; 2, *Veronica gentianoides*; 3, *Thalictrum adiantifolium*.—*F. G. B.* 1, *Anthericum liliatum*; 2, *Saxifraga* species; 3, *Helianthemum vulgare*; 4, *Geranium sylvestris*; 5, *Kalmia latifolia*.—*P. & Son*, Flower much withered, but it is probably *Marica Northiana*.—*A. B.* 1, *Weigela rosea*; 2, *Euonymus europaeus*; 3, *Spiraea arifolia*.—*J. L.* 1, *Ulmus campestris variegata*; 2, *Hippophae rhamnoides* (Sea Buckthorn).—*C. W.* 1, *Pentstemon glaber*; 2, *Hoffmannia Ghiesbreghtiana variegata*; 3, *Periploca graeca*.—*E. M. L.* *Habenaria bifolia*, the larger variety often called *H. chlorantha*.—*S. B.* 1, *Pellionia Daveanana*; 2, *Fittonia argyrea*; 3, *Veronica salicifolia*; 4, *Fuchsia procumbens*; 5, *Panicum plicatum*.—*W. D.* *Dendrobium Bensoniae*.—*A. R.* 1, *Dendrobium parvum*; 2, *Dendrobium stuposum*; 3, *Dendrobium crystallinum*.—*E. C. C. D.* *Muehlenbeckia complexa*.—*T. W. C.* Probably *Chirita sinensis*.—*H. S.* We do not undertake to name varieties of Roses; the succulent plant is *Mesembryanthemum edule*.—*C. E. A.* *Saxifraga rotundifolia*.

VINE LEAVES: *J. C.* There seems to be no fungus present, but the leaves have the appearance of having matured before their proper season, and this, we suspect, results from unsatisfactory conditions at the roots. If you have allowed the border to become dry at some period since the vines have started into growth this would be sufficient to account for the trouble.—*G. M.* The damage is caused by the Grape mildew—*Plasmopara viticola*. The fungicide advertised as Lysol should be used on the vines as given in the directions on the bottle.

WARTS ON VINE LEAVES: *J. R.* The excrescences on the leaves are not caused by *Phylloxera* or by fungus disease. They are the result of some cultural defect. The vines have been grown in too much heat and an excess of atmospheric moisture. Ventilate the vinery more freely, but with great care in order that the foliage may not be injured by cold draughts.

WALLFLOWERS: *S. F. & Co.* We have no knowledge of severe cold affecting the colour of Wallflowers, unless the plants were crippled, in which case, of course, the flowers would also be affected.

COMMUNICATIONS RECEIVED.—*W. A. C.* (with thanks)—*M. W. S. S.* (next week).—*A. W. H. H. E. R. A. H. S.* *Johannesburg*.—*G. C. H. E. S. V. N. G.*.—*F. M. W. H. P. H. A. S.*—*Miss W. R. S. K. S. AMERICAN IRISES.

WHILST there is no lack of interest taken in the Irises of the old world, particularly those of the bearded group, other species from the Continent of America are but little known, and so far as cultivation is concerned are as little understood. They all belong to the Apogon (or beardless) group, and the species are remarkable for their great diversity of form and colour, puzzling to the systematist, but a source of delight to the plantsman. He finds in their variable characters just that element of uncertainty and change that gives zest to all pursuits; for every bad form he may get there is a particularly good one as compensation. The Irises indigenous to America, so far as my studies of them show, are more than usually well distributed. A species may spread over several districts and will vary in each district—a rule of “one district one form” prevailing. This character is mainly responsible for such confusion as now exists in the nomenclature of American Irises, and such confusion will continue to exist so long as colour variation in relation to Irises is given such little consideration as it receives at present.

There is now before me a bed of seedlings of *Iris Watsoniana* flowering freely. There are no fewer than 14 distinct varieties in a given 100 plants, and the range of these alone connects *Iris tenax* with *I. versicolor* in an unbroken chain. In other species it is possible to find yellow or blue flowers of the same specific type. Such variation has its disadvantages as well as its advantages, and the best one can do is to accept “species” of American Irises as collections of forms that agree with each other in some important character.

Their value in gardens has never been realised. Some of the species and varieties are charming plants of easy culture that one can recommend as the equal of many Eastern species, and in one or two cases there is a colour scheme as unique as it is beautiful. Their cultivation cannot be described in a few words. There are water plants among them, plants suitable for the flower border, for the cool house, and for the rock garden. There are some that will not thrive in any kind of garden, but live only long enough to perfect a flower that would baffle a clever artist to portray, and then disappear. For these there is but little to be said, but fully three-fourths of the American Irises can easily be reared and grown, and the garden would be considerably the richer if all of these were included within its boundaries. Quite young plants should be used in starting a collection.

SPECIES AND VARIETIES.

I. BRACEATA.—It is scarcely possible for an Iris to have a more beautiful flower than this, and probably so bad a constitution. It forms a hard, running rhizome bearing a few very slender, sickle-shaped leaves less than half an inch wide, the margins of which are distinctly horny. There is hardly any flower stem, the long tubes serving instead. Three flowers are produced from each rhizome, and they have slender yellow tubes 8 inches long and half enclosed in broad foliaceous bracts. The broadly lanceolate “fall” petals are 4 inches long, the standards equalling these in length, but being only half their width. I have two specimens before me. One is of a greyish-lilac tint, the other is a lovely flower of pale buff-yellow suffused with amber and very elegantly traced with palest lilac on the falls, the lilac lines merging into purple at the bend of the fall and into transparency at its tip. Rarely have I seen a flower so beautiful as this. The plant is of slow growth, requiring a dry and rich soil, and to be grown between boulders on a rocky slope or in some sheltered corner, thrusting the roots as deeply into the soil as they will go. Only very young plants may be transplanted safely.

I. CAROLINIANA.—I have not seen living specimens of this species.

I. CRISTATA.—The little marsh Iris from the south-eastern U.S.A. has long been cultivated. It has running rhizomes that secure for the plant a fresh site every year, broad Pea-green leaves that are an ornamental feature all the summer long, produced in fan-shaped tufts a foot high, and the pretty sky-blue flowers are borne early in June. The flowers are but 4 inches high and 3 inches across, the style crests are daintily fringed, and the golden yellow markings on the falls are very beautiful features. This plant is closely allied to the tender *Iris japonica*. It grows best in wet mud or stony soil overlying mud, with its root-stock a few inches above water level. Once established it will bear frequent submersion of the root-stock, and will often extend its growths to the water's edge. It is an ideal plant for the bog garden and the rock pool.

I. DOUGLASIANA.—This very distinct and attractive species can be grown in any good garden soil. It is a long-lived plant with evergreen leafage of a deep bronze-green in fan-shaped clusters. The flowers average

two from each slightly flexuose stem, and they nestle among the foliage. The tubes are twice the length of the stems, the petals are coloured creamy-white in the specimen before me, heavily suffused with lilac-purple around the creamy, purple-veined signal patch, and the standards and style branches are coloured a beautiful shade of creamy-grey. A very attractive Iris whose flowers average 5 inches in diameter and whose margins everywhere are delightfully frilled and waved. It is very variable. Forms occur which approach a self purple in colour; others are practically all cream coloured with a trace of lilac here and there. A good garden plant that one can heartily recommend.

The variety known as *picturata* is a selection which has a white signal patch similar to that of *Iris tridentata*.

I. FULVA (I. CUPREA).—This old species is in many respects a remarkable plant. Botanically it connects Iris with *Moræa*. Its colouring is a lovely copper-maroon, heavily lined with yellow along the claw. The fall petals are twice the size of the standards, but all agree in their colouring; the style branches alone show a lighter tint. It is a marsh species, delighting to grow with its feet in water, and its rhizomes bedded in mud. The leaves are produced in handsome clusters 2 feet high, and the flower stems overtop these in June, and flower in July. A warm position and liberal supplies of water are very necessary for the plants, and they grow splendidly in some stagnant mudbank that absorbs heat during the day. The stems are markedly flexuose and branch freely, yielding six to eight flowers, each 4 inches across, the spatulate falls suggesting those of *Moræa*. I have seen many flowering specimens, but none showed divergence from the typical copper-maroon. It has been considered tender, but will survive any English winter if well grown. It is a poor plant under the drier conditions of a flower border.

I. HEXAGONA is one of the giants of its race. It has broad leaves and sturdy rhizomes suggestive of *Acorus calamus*. The flower stems are 5 feet high, markedly flexuose, bearing three to four flowers each, coloured a deep sky-blue with orange tracery at the bend of the horizontally poised claw, and averaging 5 inches across the flower. It comes from the Southern States, where it grows in marshes and swamps. It is too tender to withstand our winters unharmed, but may be grown in a cool house, potting it liberally and allowing plenty of room forward of the growing point. The rhizome makes a growth a foot long annually, and as many leaves are produced it is preferable to stand the pots in pans of water throughout summer. Its hexagonal fruits hang by flexible tubes to the flower stem and resemble the fruit of *Passiflora* in size and habit, but not in shape.

The variety *alba* has white flowers with paler signal patches. It is of weak growth compared with the type.

Another variety known as *Lamancei* is a hardy variety that thrives apace in bog earth or by the waterside. It has the running rhizome of the type, but shorter leaves and stems. These latter are markedly flexuose, barely 18 inches high, and bear lovely, blue flowers that are like glorified flowers of *Iris tectorum*, having a similar colour scheme. It is a very beautiful Iris that soon makes giant clumps. *G. B. M.*

(To be continued.)

THE ALPINE GARDEN.

SAXIFRAGA AIZOON ROSEA.

I FIRST made the acquaintance of this very distinct and choice plant in Mr. Farrer's group of Alpines at the Temple Show in 1905. Like other varieties of the aizoon section, this Saxifrage is a free-growing subject, and its flowers provide a pleasing tone of colour that is quite new among encrusted kinds. I am flowering the plant this season for the first time, and am greatly pleased with the erect spray of rose-coloured blossoms. Like the other members of its class, this new-comer will be seen to best advantage when planted in groups. The corymbose inflorescence is nearly 1 foot in height, slightly viscid and glandular; the pedicels are one or two flowered. The purplish colour of the petals is extremely pleasing, and is seen to the best advantage when the plant is grown in full exposure. I regard this as one of the best additions to the genus of recent years. It thrives well in a mixture of sandy loam and finely-broken old mortar. At the recent Temple Show it received an Award of Merit. E. J.

ALYSSUM MCELLENDORFIANUM.

THIS small, singularly beautiful Alpine plant has pretty glaucous foliage that much resembles that of *A. argenteum*, but the plant is much dwarfer and more compact in habit than the latter species. The bright-yellow flowers are borne on tough, wiry stems 4 inches in height. The plant is quite hardy and easy of culture, and should be planted in a rich, sandy loam in a sunny position. It should be given frequent waterings in hot, dry weather.

NOTICES OF BOOKS.

GAME AND GAME COVERTS.*

I CANNOT call to mind any book which deals exclusively with game coverts, though numerous articles on the subject have appeared from time to time in horticultural and other journals.

Mr. Simpson is therefore to be congratulated upon giving us a well-written and illustrated book on the subject, though the work is not nearly so comprehensive as could be desired—in the matter, at least, of the various trees and shrubs that have proved themselves of value for game coverts. The formation of game coverts differs so much on various estates—owing mainly to differences in soil and situation—that on no two properties do we find either the same plants in use or similar methods of distribution adopted, and what is rightly objected to in one situation is valuable in another.

Thus, the Bracken is unreservedly condemned by the author, yet some of the best shooting areas I know are woods carpeted with Bracken and contiguous to grazing fields.

Our English coppice woods, too, are invaluable game coverts at almost any age, while thinly-grown Birches and Thorns carpeted with Brambles and native grasses are hard to beat. But it should be remembered that open clearances, not dense, far-reaching masses of covert, are desirable. The remarks regarding the differences between the Austrian and Corsican Pines are good, but with possibly a wider experience of the two forms, I must agree with the late Dr. Masters in merely ranking them as varieties, though Mr. Simpson is quite right in the value of the extreme types for shelter and their immunity from the attacks of game. Contrary to the author's experience, I have always found that in order to thicken the exposed side of a plantation, early and careful thinning is necessary—it is better than the killing-out process by the survival of the fittest, as practised by some gardeners. The evergreen Oak might well be added to the list of shelter-giving trees, while the Dogwood, Sea Buckthorn, Ribes,

Viburnums, and shrubby Thorns are all useful plants for particular situations.

The book, which includes 83 pages, with 16 illustrations, is nicely got up and well printed, and should commend itself to all those who are interested in game and game coverts. A. D. W.

CYPRIPEDIUM CALIFORNICUM.

THERE are seven or eight species of *Cypripedium* hardy enough to be grown in cool and sheltered gardens without protection. Such species as *Cypripedium calceolus*, *C. humile*,

FIG. 171.—CYPRIPEDIUM CALIFORNICUM, A HARDY ORCHID: COLOUR OF FLOWERS, WHITE AND GREEN, WITH PINK BLOTCHES.

C. spectabile, and *C. pubescens* are tolerably well known, but the little, but none the less pretty, *C. californicum* has always been a rare plant. Importation from Western America is attended with difficulty—the long journey proving too much for collected specimens, whilst such old-established plants as we possess are too precious to disturb with a view to propagation. *C. californicum* is a very dainty plant that resembles *Orchis* in its habit. The root system of a good

specimen is a dense mat of tough fibres 3 square feet in extent, the living roots running just below the surface of the soil. The crowns are clustered, and there are from five to twelve in a cluster. The stems average 18 inches in height and bear six to ten flowers in a stout spike, well leaved in the lower half, but sparsely so above. The sepals are greenish, lanceolate, three-quarters of an inch long; the columns are cupola-shaped, white, with a medium line of green, and the nearly spherical pouches are white, woolly internally and with two pink blotches just below the column. The plant grows wild in the alluvial soil of Californian mountain streams, in sheltered but not shady places; its rooting medium being a mass of wet, vegetable debris, moss, &c., and its root extremities reaching to the water level. It thrives in this country under conditions enjoyed by *Parnassia* and the Bog Pimpernel (*Anagallis tenella*). The best planting season is early in spring. G. B. M.

BOTANICAL WORKS OF THE LATE DR. MASTERS.

(Concluded from page 398.)

THE principal papers on the *Aristolochiaceae* are:—"Remarks on the Structure, Affinities, and Distribution of the Genus *Aristolochia*, with Descriptions of some hitherto Unpublished Species," in the *Journal of the Linnean Society*, 1875, vol. xiv., pp. 487-495; and the monograph of the South American species in the *Flora Brasiliensis*, 1875, vol. iv., pars 2, pp. 77-114, tt. 17-26. The Linnean paper was read on February 6, 1873, though it was not published till April, 1875. Since then little has been added to our knowledge of the order, except additional species. Masters estimated the number of species of *Aristolochia* at about 200, distributed as follows:—

Brazil and Guiana	57
Central America, Mexico and Texas ...	29
West Indies	23
Northern South America	15
Peru	5
Bolivia and Paraguay	6
North America	5
South of Europe and the Levant ...	22
Peninsular India and the Archipelago ...	12
Himalayas	4
Australia	4
Tropical Africa	10
Madagascar and Mauritius	5
China and Japan	6

At least 50 species have to be added to this total, mostly from tropical Africa, South America, New Guinea, and China. The increase is greatest from China, whence we now have 20 species, and 16 species of the genus *Asarum* are on record from the same country. From the foregoing data it will be seen that *Aristolochia* is spread all over the world, excepting the colder regions. No other genus presents such variety in the size and shape of the flower. *A. Goldiana* has a flower over 2 feet in total length, and one foot in diameter; whilst in *A. nummularifolia* it is only about $\frac{1}{2}$ by $\frac{1}{4}$ of an inch. The flower of *A. trilobata* is like the pitcher of a *Nepenthes*, except that the part corresponding to the operculum has a long tail. In other species it is like a *Masdevallia*, except that the tube is longer. Pollination or fertilisation is effected by insects conveying the pollen. In reference to this Masters says: "I may point out the frequency with which a membranous process pointing downwards and inwards is formed in the flower-tube of certain species of *Aristolochia* between the basal distended portion and the median tubular portion of the perianth. This process has been for the most part overlooked by descriptive authors. . . . It is generally a mere rim; but in other cases it is more highly developed, and is so placed as to prevent the egress of insects which may have entered." In *A. Clematis*, and other species, the narrow tube is furnished inside with deflected hairs, which at first effectually bar the outward pas-

* *Game and Game Coverts*, by John Simpson. Published by Pawson & Brailsford, Sheffield; price 15s.

sage of insects. But, as Hildebrand has shown, these hairs shrivel up later, leaving an open passage; otherwise, cross-fertilisation could not be effected. It is probable that the membrane described by Masters alters its position at some period, and thus allows the going to and fro of insects.

In the same volume of the *Journal* of the Linnean Society, pp. 495-507, tt. 14-16, is a "Monographic Sketch of the Durioneæ" by Masters.

Dr. Masters also contributed to the *Encyclopædia Britannica*, and, going back to 1866, I find that he was one of the principal contributors to that useful work, *The Treasury of*

in cultivation, the elegant *Restio subverticillatus*, Masters, being an exception. This has been in cultivation many years, originally under the name of *Willdenovia teres*. It was first described by Dr. Masters in his "Observations on the Morphology and Anatomy of the Genus *Restio*, Linn., together with an Enumeration of the South African Species," in the *Journal* of the Linnean Society, 1865, vol. viii., pp. 211-254, tt. 14 and 15.

The Restiaceæ are an exceedingly interesting group botanically, being mostly dioicous plants, the two sexes of the same species being sometimes so different in aspect as to have been taken for different genera. Besides a number of

Masters was also author of some elementary books, the chief being *Botany for Beginners* and *Plant Life*, of both of which, it is recorded, Russian, French, and Dutch translations have appeared. He was also editor, or part editor, and author, of the second, third, and fourth editions of Henfrey's *Elementary Course of Botany*.

Reference has been made to Masters' work on the Malvaceæ. Among the many new species of that order described by him are two of more than ordinary interest, namely, *Gossypium Kirkii* and *G. Stocksii*, wild cotton plants, the former a native of tropical Africa, the latter of Scind.

No one will ever know how much Dr. Masters wrote on practical horticulture or cultivation in the *Gardeners' Chronicle*, but we know that he was joint author with the late Sir Henry Gilbert, or sole author, of certain "Reports of Experiments made in the Gardens of the Royal Horticultural Society at Chiswick in 1869 and 1870 on the Influence of Various Manures on Different Species of Plants." He was also joint author of an elaborate report on the "Results of Experiments on the Mixed Herbage of Permanent Meadow, Conducted for More Than Twenty Years in Succession on the Same Land: Part 2, Botanical Results," in the *Philosophical Transactions of the Royal Society*, 1883, vol. clxxiii., pp. 1,181-1,433.

The foregoing uncritical and somewhat disjointed review of the late Dr. Masters' botanical writings outside of the *Gardeners' Chronicle* is incomplete, but it is sufficient to give an idea of the immense amount and great variety of work he accomplished, and it may be useful for reference.

In conclusion, I should like to put on record in the first person my appreciation of our departed friend, with whom I have been well acquainted ever since 1865, and whom I knew several years previously as an occasional visitor to the Herbarium at Kew. Before my breakdown in health in 1867, and the consequent resignation of the post I held at Kew, I was a budding contributor to the *Gardeners' Chronicle*, and, as soon as I was well enough to resume work, Dr. Masters put all he possibly could in my hands that I was capable of doing. During the many years that I had to live entirely on my pen this kindness was continued, with great liberality in material acknowledgment. But it is not so much my gratitude for benefits received that I wish to express, as my esteem and admiration for the genial man who steered his ship so well and wisely through often-troubled waters. *W. Botting Hemslley.*

THE CONSTRUCTION OF DRIVES AND PATHS.

(Concluded from page 397.)

TREATING the different materials according to their individual merits, a grey basalt or granite makes the best foundations for heavy traffic, but the stone is not always easily obtainable. Blue or red limestones occur plentifully in some districts, and as they contain a good percentage of silica and iron, they also make durable roads.

Grey and yellow limestones are more brittle, and not to be recommended for heavy wear, but will do well for footpaths and light traffic, and have the advantage of setting very quickly, owing to the soft nature of the stone. Shingle is a good material for paths intended for light traffic, but, owing to the roundness of the stones, they will not "set" easily unless mixed with a certain proportion of clay. Firebricks, common bricks, and cinders where obtainable in sufficient quantities are excellent materials for ordinary purposes, and constantly maintain a good dry surface, even in wet weather. Builders' refuse, consisting of broken bricks and other more or less durable materials, may also be used, provided it is well rolled and thoroughly soaked with water.

FIG. 172.—*BRYOPHYLLUM CRENATUM*; CALYX PURPLE, PETALS PALE YELLOW.
(See page 422 and Supplementary Illustration.)

Botany, his initials appearing on every other page at least. It may be mentioned in passing that a new edition of this book would be very welcome. I have seen in more than one place, including *Men and Women of the Time*, that Masters was a contributor to De Candolle's *Prodromus*; but it was De Candolle's *Monographia Phanerogamarum* to which he was a contributor, having elaborated the Restiaceæ for that work, vol. i. (1878), pp. 218-398, tt. 1-5. This natural order, comprising 20 genera and about 240 species, is almost entirely confined to South Africa and Australasia. Solitary outliers are recorded from Chili and CochinChina. They are rush and sedge-like plants, almost unknown

smaller contributions to the literature of the order, Dr. Masters was author of the Restiaceæ in Hooker's edition of Harvey's *Genera of South African Plants*, 1868, and in the *Flora Capensis*, vol. vii., pp. 59-149.

Irrespective of the orders which he specially studied, Dr. Masters published a number of small articles on morphology and anatomy, among them:—"Vegetable Morphology: Its History and Present Condition," *Brit. For. Med. Chir. Rev.*, 1862, vol. xxix., pp. 202-218; "On the Morphology and Anatomy of *Philydium lanuginosum*, Br.," *Journal of Botany*, 1863, vol. i., pp. 105, 106; "On the Anatomy of the Leaf-stalk in *Thalia dealbata*," op. cit., p. 107.

Clay by itself is not to be recommended, but when worked into with a good layer of gravel it will serve its purpose well.

There are other more or less artificial methods of providing a road with a good surface, but these do not come within the scope of this article. The ultimate durability of a drive or path will depend largely upon the care that is taken in laying on the surface. The newly-excavated drive should first be provided with a solid edging of fairly large stones, partly sunk into the ground in order that they may not protrude above the finished surface; a layer of stones, each as nearly as possible 6 inches square, should then be packed carefully and closely with their broadest end downwards over the surface. Similar stone, broken up small enough to pass through a ring 2 inches in diameter, should then be spread over the first layer in such a manner as to completely cover it. The surface should afterwards be well watered, and a good heavy roller brought into play, or if a traction engine be available so much the better. The addition of a coating of sand or fine gravel will serve to make the rolling more effective. A layer of coarse chippings should be carefully worked into the stone foundations, followed by about 2 inches of finer chippings or gravel laid on in two coatings of 1 inch at a time, and well rolled on each occasion. The chippings or other surface material used should first be passed through a screen. After the construction of the drive is finished, it should be reserved from traffic for three or four weeks if possible. When traffic is commenced, it should be frequently diverted from one side of the drive to the other, in order to wear the surface evenly, until it becomes thoroughly set. I have found from experience that these necessary practices are not always willingly carried out, but they may be enforced on drivers of vehicles by placing large stones on the surface of the drive in such a manner as to steer the traffic into the desired direction, moving the stones occasionally to other points as the requirements demand.

A drive intended for light traffic should also be provided with a good foundation of about 6 inches of suitable, porous material, but the layer of larger stones at the bottom may in this case be dispensed with. Gravel or chippings should be added after the manner described, and a good rolling of the surface is essential.

Footpaths may be treated in the same way, if modifications are made according to the material used for their construction. *P. Mayer.*

ORCHID NOTES AND GLEANINGS.

ODONTOGLOSSUMS FROM MONCREIFFE.

THE excellent quality and fine culture of the plants of *Odontoglossum crispum* in the gardens of Sir Robert D. Moncreiffe, at Bridge of Earn, N.B., is well shown by a series of flowers sent by his gardener, Mr. A. Common. The white forms are of the very finest type, and among the spotted varieties are several of the *O. crispum* Trianae and *O. crispum* guttatum classes. The freshly imported plants developed at Moncreiffe have been prolific in blotched varieties, the best of which is the fine *O. crispum* Lady Moncreiffe, for which an Award of Merit was given at the Royal Horticultural Society on May 19, 1903.

VANDA TRICOLOR SUAVIS.

A COMPLETE inflorescence, with all the flowers exhibiting the same peculiar deviation from the normal type, is sent us from the gardens of Monsieur le Comte Henri Visaert de Bocarmé at St. Croix, near Bruges, Belgium. The petals are incorporated with the sepals, and thus the flowers are composed of three enlarged sepals and a labellum, all being so symmetrically arranged that the beauty of the flowers is retained, without any striking appearance of abnormality, the petals having become part of the sepals without the twisting of the parts often seen in such cases. The three segments, which are much broader than usual, are of cream colour, evenly blotched with red-brown, and, as in the normal form the petals and sepals are similarly coloured, the combination of both is the more perfect. The column and side lobes of the lip are white and the front of the lip rose colour.

The Week's Work.

THE KITCHEN GARDEN.

By WILLIAM H. HONESS, Gardener to C. COMBE, Esq., Cobham Park, Surrey.

Celery.—The earliest plants that were pricked out will now be large enough and quite ready for planting out in the trenches. The trenches should be from 4 to 5 feet apart from each other, but directions for preparing these have already been given in a previous calendar. The newly-transplanted plants should be frequently sprinkled overhead with soot, as a check to the "fly" or leaf miner. Lift only a small number of plants at one time, so that the roots will not suffer from long exposure. Apply water to each trench as the work of planting proceeds, and immediately follow this with a sprinkling of soot.

Asparagus.—Cutting should now cease for the season, in order that the plants may acquire strength in the crowns for furnishing a good crop next year. The beds should be thoroughly cleared from all weeds, and be given a final dressing of artificial manure, as previously advised.

Cabbages and Coleworts.—If a sowing of these be made at the present time, the plants will prove most serviceable for the furnishing of vacant ground as the different crops are cleared off, and in autumn the late Cabbages and Coleworts will be valuable.

Lettuce.—Sowings of both the Cos and Cabbage varieties must still be made frequently. If any of the previous plantings should suffer neglect in the matter of watering during hot or dry weather, "bolting" will follow immediately, and the batch be lost.

Cauliflowers.—No vegetable suffers more quickly from dryness at the root than do Cauliflowers, and the complaints that one often hears of buttoning are generally brought about through this cause. Water should be frequently and liberally applied to this crop, and, if possible, let liquid manure be afforded at every alternate watering, applying mulchings also in order to conserve the moisture and maintain the soil cool. It is unfortunate that mulchings are apt to have such an untidy appearance; it is impossible to employ them in some cases where their effects would be most valuable.

Parsley.—For the purpose of providing a good supply during the winter, a sowing might now be made. This crop, like most others, pays the grower well for liberal treatment at the root. A dressing of manure from a spent mushroom is as good as anything, and, as plants from this sowing will be for winter use, it will be well to sow the seeds in a warm and sheltered position. Select the most ornamental or best curled varieties of Parsley, as these are quite as hardy as those which are less ornamental.

Globe Artichokes will now be starting to develop their "chokes." If the plants are growing in very light ground, let them be afforded frequent and copious applications of liquid manure.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower to Sir Trevor Lawrence Bart., Burford, Surrey.

Cattleyas and Lælias.—In collections containing Cattleyas, Lælias, and their hybrids, there will usually be some plants that require attention as to re-potting, &c. Therefore it is a good plan to look over these plants (especially those which are rare and valuable) every day, selecting for receiving immediate attention those which have overgrown their pots, and others that are worn-out masses and therefore need rejuvenating, either by re-making them up into small, neat specimens or by placing the pieces singly into suitable-sized pots. These remarks apply particularly to such plants as Cattleya Mossiae, C. Mendelii, C. Skinneri, C. intermedia, C. Schröderae, C. Harrisoniae, C. amethystoglossa, Lælio-Cattleya Myra, L.-C. G. S. Ball, L.-C. Dominiana, L.-C. Haroldiana, L.-C. eximia, L.-C. Fascinator splendens, &c.; also several of the Brasso-Cattleya and Brasso-Lælia hybrids, and others. For instructions as to re-potting, composts, &c., readers may refer to the Orchid Calendar for May 18. Many beginners in Orchid culture often find the watering of their plants, especially Cattleyas and Lælias, a difficult performance, not knowing for certain whether they have given too

much or too little, but with careful study and experience they gradually become more confident and accustomed to the work. The inexperienced cultivator, as soon as he observes a slight shrivelling of the pseudo-bulbs of plants which have recently been re-potted, frequently commits an error by thoroughly watering the plant with the idea of making it plump. This it will do for a time, but the old roots, instead of pushing out fresh ones, rapidly decay from excess of moisture, and very often cause the loss of the plant. The safer plan when watering freshly re-potted Cattleyas and Lælias is to keep the compost rather on the dry than on the wet side, and to carefully water the soil around the edge of the pot until each plant has become firmly re-established, when with plenty of new roots present, and the growths progressing favourably, the amount of water may be gradually increased; but no plant should receive water at any time until the whole mass of compost has first become thoroughly dry. Plants which are in large pots, and have considerable material to root in, do not become dry so quickly, or require so much water at one time as those in smaller pots that are well rooted. Wood-lice do much mischief to the young growing roots of these plants, and means must constantly be taken to catch them; large numbers may be trapped with hollowed-out pieces of Potato. Many may be seen on the surface of the soil after the plants have been watered. Afford fresh air to the Cattleya-house whenever this is practicable. If the temperature of the outside atmosphere is 50°, the bottom ventilators should be left wide open, employing enough fire heat at night to keep the atmospheric temperature of the house at 65°.

PUBLIC PARKS AND GARDENS.

By W. W. PETTIGREW, Superintendent of the Parks and Open Spaces in the City of Cardiff.

Bathing in parks.—The provision of bathing facilities in cities usually falls upon a special municipal department, but it often happens that the presence of a lake or large pond in a public pleasure ground makes it possible for the parks department to provide open-air bathing accommodation easily and cheaply. Where this is done a much-appreciated boon is conferred upon the public. Open-air bathing is, as a rule, possible only in parks which are situated some distance from the smoke and dirt of factories. When these favourable conditions do not obtain, the water is better covered with a roof, and it is then scarcely in keeping with the ordinary surroundings of a park. In those parks possessing lakes or ponds suitable for bathing purposes such as those supplied by a constant stream of clean water, very little expense need be incurred in adapting them to the requirements of an open-air bath. A stage, constructed either of wood or concrete, built close to the edge of the water and fitted with plain plank seats, and a few diving boards overhanging deep water are, as a rule, all that is necessary. Dressing-boxes under such circumstances are not usually provided, but the stages are screened at the backs and sides with trees and shrubs, so that from most points of view the bathers are out of sight of other visitors whilst undressing and dressing. For obvious reasons bathing must be restricted to certain parts of the water and to special hours of the day when ornamental waters are put to this use. All-day bathing could hardly be permitted under any circumstances, but more especially where boating is carried on.

In some parks, where natural facilities for bathing do not exist, open-air baths have been constructed to meet the needs of the bathing public. In forming these the excavated material is usually tipped in the form of high mounds all around the site. When these banks are thickly planted with trees and shrubs, the water is hidden from view, and in consequence they can be used all day.

As a matter of course the cost of upkeep of these baths is greater than in the case of a lake used for the same purposes. The most important and usually the most costly matter is the water supply. This must be clean and plentiful, as a much-frequented bath should be emptied and re-filled twice or three times a week. When partly filtered water can be taken in sufficient quantities from a stream, the cost of maintenance need not be great, but if the supply is only obtainable from a water company, it can hardly fail to be high.

Payment for bathing.—The question as to whether or not a charge should be made for the use of the baths or lakes for bathing purposes is a much debated one. The general opinion is that where maintenance charges are not great, bathing for many reasons should be free; where the provision of bathing accommodation results in a heavy outlay, those benefiting by the accommodation should be made to contribute direct to its upkeep.

An attendant necessary.—The use of swimming baths is attended by a decided element of danger, and every precaution must be taken by the responsible officials to guard against accidents. Where the depth of water is more than 4 feet, an expert swimmer should always be in attendance to look after the safety of bathers. Where swimming is allowed in lakes, this gentleman should be on the water in a boat, from which he can throw life-lines, pick up exhausted swimmers, or render any other assistance needed. Eleven years ago, in consequence of two drowning accidents, this method of protecting bathers was adopted in one of our parks, and, although since then over 250,000 persons have used the lake, no further fatality has occurred.

PLANTS UNDER GLASS.

By J. G. WESTON, Gardener to H. J. KING, Esq., Eastwell Park, Kent.

Chironia floribunda.—This extremely ornamental flowering plant is fairly easy to propagate; cuttings made from the young shoots, taken in spring, rooting without any difficulty in a frame in the propagating house. Such rooted cuttings having been potted singly into small 60's (2½-inch pots) will now be ready for repotting. Be careful not to place them in pots that would be too large; those measuring 4 inches or 5 inches in diameter being quite large enough for them during the first season. The roots are very fine, and if over-potted would be liable to suffer from an excess of water. At all times the operation of watering should be carried out with the utmost care, but more especially is this necessary during the winter months, when the supply has to be much restricted. For the present potting, a compost should be used which is of a light nature, and contains turf in only a partially broken condition. If two parts peat, one part loam, and one part leaf-soil are mixed, with a liberal addition of sharp sand to keep the whole porous, this will be a suitable mixture. The older plants should be neatly staked and tied, for they will soon be showing bloom. Younger plants rooted this spring will form a succession later in the season. Whilst in the earlier stages of growth the plants should be kept in a light position in a warm house, but as they become more advanced an intermediate temperature will be found suitable. When in flower, Chironias show to great advantage if staged thinly amongst Adiantum Ferns in a cooler house than that in which they made their growth.

Gloxinias.—Plants in bloom should be placed in a cooler and drier atmosphere, the blooms lasting in good condition longer than if kept in a warm house under the same conditions as for cultivation. Well-flowered plants standing on inverted pots are very effective amongst Ferns or other foliage plants. A few plants if staged in this manner have a more pleasing appearance than a larger quantity grouped by themselves. Re-pot the batches of seedlings as required.

Chrysanthemums.—Get all arrears of potting finished as soon as possible, as plants that become starved and stunted through being pot-bound rarely grow satisfactorily afterwards. Afford stakes to the plants when they have been potted, and fasten the stakes securely to wires in their permanent positions as a protection from wind. Endeavour to allow each plant sufficient room for development, and sufficient to permit a perfect circulation of air between each. If a proper compost is used when potting, no feeding will be required for some time to come. The grower, however, must be guided by the appearance of the plants in determining when stimulants are necessary. Keep a look-out for the first appearance of mildew, and take preventive measures early. If aphides are troublesome, apply tobacco powder frequently, and syringe the plants occasionally in the evening with clear diluted soot water.

FRUITS UNDER GLASS.

By ALEXANDER KIRK, Gardener to J. THOMSON PATON, Esq., Norwood, Alloa, Clackmannanshire.

Early Vinerias.—When all the Grapes have been cut from early vines, the foliage should be thoroughly syringed twice daily, unless the weather is dull and wet, when a morning syringing will be sufficient. This practice will help to maintain the vines in health, and will keep red spider at bay, if an abundance of ventilation is afforded both day and night.

Grapes commencing to colour should receive careful attention. They must not be hastened into ripening by an excess of artificial heat, and it should be remembered that the variety Black Hamburgh finishes best when given a fairly cool treatment. If the variety Madresfield Court has finished the stoning of its berries, and they begin to colour, the atmospheric moisture must be reduced in amount. Allow the air to circulate amongst the vines by opening the top and bottom ventilators a little; also circulate a little heat from the hot-water pipes for the same reason, and do not entirely close the ventilators at night-time. Excess of moisture in the atmosphere in which they are growing causes the berries of this variety to split, and scalding in the fruits is also brought about by the same cause. The day temperature of theinery should be 85°, and the night 70° with a dry atmosphere. Test the borders both inside and outside, and if they are found to be dry, give a good watering with manure water, after which application the vines will probably not require any more moisture at their roots until the bunches are mature.

Late Grapes.—The bunches should be examined and have their berries thinned, so that the fruits which remain may have space to develop to the fullest size. As soon as the variety Lady Downes has finished the stoning of its berries, special treatment must be given to prevent the fruits scalding. Keep the house cool and well ventilated throughout the day-time, open the top and the bottom ventilators slightly at night, and keep the water circulating in the hot-water pipes. The night and day temperatures should vary little—70° at night and 10° higher by day will be suitable. Never entirely close the house for a period of about 15 days.

Strawberries.—It is now time to prepare for next season's plants in pots. The first batch of runners should be pegged down into 3-inch pots. The receptacles should be filled with a mixture of fresh loam and leafmould. Plunge the pots in the Strawberry-beds, and peg the runner into them with wire pegs. Never allow the stolons to become dry. They will soon form roots, after which they must be potted into their fruiting pots. Later batches of runners which have been pegged down can be detached, and be potted at once into their fruiting pots with very good results. Place them in a cold frame, where they will soon root into the fresh compost. Keep the frames close for a few days, and afterwards gradually expose the plants to full sunshine.

THE FLOWER GARDEN.

By A. C. BARTLETT, Gardener to Mrs. FORD, Pencarrow, Cornwall.

Clematis montana.—Now that they have finished flowering, many old plants will need overhauling, or they will become tangled masses, and fail to be as effective as could be desired. Many of the shoots which have flowered should be cut out, and this year's growths be trained in their place. A mulching of good organic manure, or a dressing of some quick-acting artificial manure would be of assistance, and plants which are growing against walls should be afforded a good watering. The summer-flowering Clematis will flower better and longer if they receive some manurial assistance.

Pyrethrums and Delphiniums should be trimmed of their inflorescences as soon as the last flowers fade. Lightly prick over the surface soil, and apply some manure. These plants will then yield some useful flowers in the autumn.

Carpet bedding.—Where this style of gardening is still practised, the flower-beds will now require constant attention to make the designs a success. Such beds, if laid out in grass, will require to be edged even more frequently than others, for in their case a hard and fast outline is essential. The plants must be frequently

pinched, or they will not assume that brilliant colouring which is one of the chief attractions of carpet bedding. The Alternantheras especially lose colour if pinching is neglected, because that portion of the plant so shaded becomes greenish and dull.

Intermediate Stocks.—If seeds are sown at the present time, the plants will have a sufficiently long period of growth to enable them to successfully withstand the winter. Sow the seeds thinly on a warm border, where a fine tilth has been prepared. Thin out the seedlings when they are large enough to handle, and plant them in their flowering quarters towards the end of the autumn.

Herbaceous Pæonies.—After these handsome plants have ripened their foliage, there are large blanks left by them in the herbaceous borders. These can be partly furnished if some annuals were transplanted so that they have formed nice balls of soil ready for planting around the crowns of the Pæonies after the leaves have died. The Pæony leaves must not be cut away prematurely, or the quality of next year's flowers will suffer.

Gravel paths.—We have experienced such a wet season that the weed killer applied in the spring has now lost its efficiency, and tiny weeds are showing, which necessitates another application of the weed killer. These compounds, or solutions, are of such a deadly nature that, as previously advised, every precaution should be taken to prevent accidents attending their use.

THE HARDY FRUIT GARDEN.

By J. MAYNE, Gardener to LORD CLINTON, Bickton, East Devon.

Summer pruning is a necessity in the case of trained trees, and my system is to perform the work from midsummer day until it is finished. Growth during the present cold and comparatively sunless season is less advanced and not so firm as usual, consequently summer pruning has been deferred for ten days or more. Trees of weakly growth should be lightly pruned, deferring the work in their case until the last. Trees planted against warm walls are naturally more forward than those occupying less congenial quarters, therefore they will claim first attention. Cut back to within 4 inches or so of their origin lateral shoots that are not wanted, leaving any that are required for covering bare spaces or for extension until the winter pruning. To avoid causing a sudden check to the tree, it is advisable to do the upper part first, and the lower half a few days afterwards. Gather up all the prunings daily and burn them, by which means many insect pests will be destroyed. As soon as the wall trees have been pruned, the shoots that are left should be tied or nailed to prevent them breaking.

Budding fruit trees.—Stocks for budding can easily be raised by sowing the stones of Peaches, Apricots, Plums, and Cherries, as well as the pips of the Apple and the Pear. July and early August are the best times to insert buds on fruit trees, choosing dull and showery weather for the operation. Half-ripened wood of medium-sized shoots of the current season provides the best buds. Cut out each bud with some bark and wood attached, 1½ inch long, eventually removing the wood with the haft of the budding knife, and leaving only the pith, which should be full or prominent at the "eye." Previous to cutting out the bud, prepare the stock at the desired height by making an incision an inch long with a cross cut at the top, thus forming a T: the cut should not go deeper than the bark. Raise the edges of the cross cut with the handle of the knife, and insert the bud without damaging it. Bind the stock and bud moderately firm with raffia, commencing to tie at the bottom of the cut, and so completely that no air can reach the wound.

Strawberries.—Runners should be layered early for planting in the open garden in August or early September. Pots 3 inches in diameter are the most convenient, and these should either be stood or plunged in the rows. Fill the pots moderately firm with fresh loam; a few rough pieces of turf-loam at the bottom of the pots will afford the necessary drainage. Peg the runners in the pots, using only one plant from each stolon, and keep the roots well supplied with water. Remove any leaves from the old plants that are likely to unduly shade the plantlets.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

APPOINTMENTS FOR JULY.

TUESDAY, JULY 2—
Scottish Hort. Assoc. meet.
Nat. Amateur Gard. Assoc. meet.

WEDNESDAY, JULY 3—
Hanley Park Floral Fête (3 days).
Baling Fl. Sh.

THURSDAY, JULY 4—
Nat. Rose Soc. Sh. at Botanic Gardens, Regent's Park.

SATURDAY, JULY 6—
Soc. Franç. d'Hort. de Londres meet.
German Gard. Soc. meet.

TUESDAY, JULY 9—
Roy. Hort. Soc. Summer Exh. at Holland Park (3 days).
Wolverhampton Fl. Fête (3 days).
Roy. Scottish Arbor. Soc. Exh. in Edinburgh (4 days).
Cambridge Fl. Sh.

WEDNESDAY, JULY 10—
Tunbridge Wells Fl. Sh.
Croydon Fl. Sh.
Brixton, Streatham and Clapham Hort. Soc. Sh. (provisional).
Bath Rose Sh. (3 days).
Southend-on-Sea Fl. Sh.
Newcastle-upon-Tyne Fl. Sh. (3 days).
Lee, Blackheath & District Fl. Sh. (2 days).
Hereford & West of England Rose Sh.

THURSDAY, JULY 11—
Addlestone, Chertsey and Ottershaw Fl. Sh.

SATURDAY, JULY 13—Woodbridge Fl. Sh.

TUESDAY, JULY 16—
Nat. Sweet Pea Soc. Sh., Horticultural Hall, Westminster.
Salthire Rose Sh.

WEDNESDAY, JULY 17—
Women's Agric. and Hort. Union Exh. in Bot. Gardens, Regent's Park.

SATURDAY, JULY 20—German Gard. Soc. meet.

TUESDAY, JULY 23—
Roy. Hort. Soc. Coms. meet.
Brit. Gard. Assoc. Ex. Council meet.

WEDNESDAY, JULY 24—
Nat. Carnation Soc. Sh. in R.H.S. Hall, Westminster.
Cardiff and County Fl. Sh. (3 days).
Harpenden Fl. Sh.

THURSDAY, JULY 26—
Roy. Ulster Agricultural Society's Exh. and Fl. Sh., Balmoral, Belfast (2 days).

FRIDAY, JULY 26—Roy. Bot. Soc. meet.

SATURDAY, JULY 27—Lydney Fl. Sh.

WEDNESDAY, JULY 31—
Midland Carnation & Picotee Soc. Exh. in Birmingham Bot. Gardens (2 days).
Chesterfield Fl. Sh.
Bishop's Stortford Fl. Sh.

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich—61.5°.

ACTUAL TEMPERATURES:—

LONDON.—Wednesday, June 26 (6 P.M.): Max. 70°; Min. 55°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—Thursday, June 27 (10 A.M.): Bar. 29.9; Temp. 60°; Weather—Overcast.

PROVINCES.—Wednesday, June 26 (6 P.M.): Max. 62°. Lancaster; Min. 52°, Scotland W. coast.

SALES FOR THE ENSUING WEEK.

FRIDAY—

Choice imported and established Orchids from various sources, at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.45.

Professor Sargent, and dated Ichang, April 21st, 1907:—

"I returned here on the evening of the 19th inst. after an absence of 18 days. Everything went well on the journey, but the weather was wet for the most part, making travelling uncomfortable. I visited a part of the mountainous region to the west south-west of Ichang—a part where I had not previously been, reaching an altitude of about 7,000 feet. The woods in the mountains were still as dormant as in mid-winter, and snow was lying on the crevices. In the ravines and open valleys vegetation was advancing, and I made a collection of about 180 species of trees and shrubs. Deciduous trees belonging to the Incompletæ were very abundant. I noted several species of Populus, Ulmus, Celtis, Betula, Carpinus, Corylus, and many species of Oaks. I saw many trees of Fagus longipes—more than I have met with elsewhere. For the first time, too, I found a living example of Gymnocladus chinensis. The specimen was a fair-sized tree, being about 40 feet high. It was growing at an altitude of 3,600 feet.

"The rose-pink-flowered Magnolia (referred heretofore to *M. conspicua*) was fairly common at an altitude of between 3,500 and 5,000 feet, and was a beautiful picture, being one mass of flowers.

"In the woods at an altitude of between 3,500 and 5,000 feet the Sassafras was abundant. It was in full flower and consequently very conspicuous. There were hundreds of trees, varying in size from 12 to 50 feet in height. I examined the flowers of many of these trees, and they all appeared to be normal and hermaphrodite. However, I am inclined to think that the tree is usually dioecious. The plant has no medicinal value, the wood being simply used for fuel.

"Alongside the mountain paths and elsewhere the Cherry trees made a fine display. I collected specimens of five species. Of shrubs in the mountains, *Hamamelis mollis* was the most beautiful with its wealth of yellow flowers. On the low hills *Loropetalum chinense* was a sight never to be forgotten. The conifers were especially interesting and noteworthy. *Keteleeria Davidiana* was abundant in places at altitudes between 1,500 and 3,500 feet. I gathered cones 8 inches long! But the most interesting discovery of the whole journey was *Pinus Bungeana* growing wild. It was growing on steep, precipitous mountains at an altitude of 2,000 to 4,000 feet. There were many hundreds of trees scattered along for many miles, evidently the remains of a considerable forest. The trees vary considerably in size, and one and all had the characteristic white bark. Many were bent at a sharp angle immediately above the ground, then becoming vertical; few only branched from a point near the ground. The wood is brittle and, therefore, used only for fuel. The situation and conditions under which the trees are growing preclude any possibility of their having been planted. There cannot be a shadow of doubt about their being truly indigenous to this particular locality. If this species (*P. Bungeana*) is also truly wild in the mountains north of Pekin, why should not *P. Koraiensis* also occur here as was thought to be the case by the late Dr. Masters? If *P. Bungeana* is not truly wild near Pekin, then this is the district from whence it has been introduced.

"I collected a Pine new to me on the cliffs at 6,600 feet. It has black, ragged bark, very smooth cones, and two rather short, stiff needles in the sheath.

"*Pinus Armandii* was common on precipices at an altitude of 5,000 to 6,500 feet. This species forms a very graceful tree, but apparently does not attain to any considerable size.

"Amongst the economic problems cleared up during this journey is one upon which I have had considerable doubt, namely, that the seeds of the Varnish tree (*Rhus vernicifera*) yield, when submitted to pressure, an oil used for culinary purposes and for the manufacture of candles. I saw the whole process in operation. I discovered also a new use for the wood-oil (*Aleuritis Fordii*). It is used in the country as an illuminant, and is considered superior to rope-oil for this purpose."

OUR SUPPLEMENTARY ILLUSTRATION to the present issue represents a portion of the inflorescence of *Bryophyllum calycinum*, a fleshy, succulent evergreen shrub, native of India, and allied to *Kalanchoe*, having cream-coloured flowers shaded with pink. It requires a moderate stove temperature in this country, and if the flowers cannot lay claim to being exceptionally showy, the plant is nevertheless interesting, for it possesses the singular property of producing buds from each of the indentations along the margins of the leaves, when the latter are laid on the surface of moist soil. The leaves have even been known to form young plants along their margins after being pressed for preserving in the herbarium. The genus *Bryophyllum* is a small one, and only five good species are enumerated in the *Index Kewensis*. *B. calycinum* with *B. crenatum*, a new species from Madagascar, having purple and yellow flowers, a drawing of which is reproduced at fig. 172, are the best known species in gardens.

ANNUAL FESTIVAL DINNER OF THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—

The sixty-eighth annual festival dinner of the Gardeners' Royal Benevolent Institution took place on Wednesday evening last at the Hotel Metropole. The chair was occupied by the Hon. WALTER ROTHSCHILD, M.P., who was supported on the right hand by the Rt. Hon. Colonel MARK LOCKWOOD, M.P., and Sir WALTER SMYTHE, Bart., and on the left by Sir EDGAR SPEYER, Bart., and STUART M. SAMUEL, Esq., M.P. A very distinguished company was present, the number exceeding any previous attendance. The toast of "Continued Success to the Gardeners' Royal Benevolent Institution" was proposed by the Hon. WALTER ROTHSCHILD, M.P., and responded to by Mr. HARRY J. VEITCH, treasurer of the Institution and chairman of the Executive Committee. Mr. SAMUEL, M.P., proposed "Horticulture in all its Branches," and Colonel LOCKWOOD, M.P., responded. Other toasts included that of "The Chairman," proposed by Sir EDGAR SPEYER, Bart., and "The Secretary," proposed by Sir SAMUEL BYTHE, Bart. The receipts from donations and subscriptions amounted to nearly £2,500, a larger sum than has ever been raised in connection with the annual festival. The list included an annual subscription of £5 5s. from H.R.H. the PRINCE OF WALES (president), and £105 from the Hon. WALTER ROTHSCHILD, M.P. Mr. HARRY J. VEITCH referred to the recent losses sustained by the Institution, mentioning the names of the late Dr. M. T. MASTERS, vice-president, and HARRY TURNER and GEORGE NORMAN, members of the committee. We shall hope to refer to the proceedings in our next issue.

A Letter from China.

Our readers may remember that, at the close of last year, Mr. E. H. Wilson left this country in order to make a third visit to China, this time under the auspices of Professor Sargent, of the Arnold Arboretum, Massachusetts. The accounts of Mr. Wilson's previous visits to China as plant collector for Messrs. James Veitch and Sons, published in these columns in 1905 and last year, met with such high appreciation, we have much pleasure in printing the following extracts from a letter written by Mr. Wilson to

INFLORESCENCE OF *BRYOPHYLLUM CALYCINUM* ; COLOUR OF FLOWERS CREAM
SHADED WITH PINK.

THE R.H.S. COMMITTEES HAVE A PLEASANT OUTING.—A party of some 40 members of the various R.H.S. committees, who had accepted Mr. HARRY J. VEITCH's invitation to visit East Burnham Park, travelled to Slough on the morning of the 21st inst., where they were met by Mr. VEITCH, who had provided brakes, in which the visitors were conveyed to the park. In order that the natural beauty of that part of Buckinghamshire might be the better enjoyed, the journey was made via Stoke Park, a very extensive and well-wooded demesne; also by Stoke Poges churchyard, so famous because therein lie the remains of the author of "Gray's Elegy." From thence through country lanes embowered in leafy trees, and with hedges aglow with the wild Rose, the party passed through the ancient village of Farnham Royal and so on to East Burnham Park. Here the greater trimness of the hedgrows, and the trees, shrubs, and park-like expanses, with some glorious masses of colour from climbing Roses lighting up here and there, showed the visitors at once that they were near the home of a distinguished horticulturist. In the pleasure grounds roomy tents had been erected, and in these refreshments were served before an inspection was made of the gardens. The glorious effects of the yellow Austrian Briar were seen in many directions. The climbing Roses on arches, pergolas, or pillars, were much admired. These included such varieties as The Dawson, of soft rose colour; Paul's Carmine Pillar, Electra (white), Mad. Alfred Carriere (a splendid double white), Aglia, and many others. The wild-garden, associated as it is with water and rockwork, also elicited much admiration, and gardeners were continually noting something they saw for the first time. The survey over, luncheon followed, and at its conclusion Mr. W. MARSHALL proposed the healths of Mr. and Mrs. VEITCH, to which Mr. VEITCH responded, and said that he hoped the visit might be regarded as an annual one. A cricket match then took place, the captains being Messrs. W. HOWE and JAMES GIBSON. Mr. HOWE's side batted first, but were very unfortunate, and were all out for 18 runs. Mr. GIBSON's side followed, their captain scoring 37 runs, and the entire side getting 111 runs. Mr. HOWE's side resumed the batting, and Messrs. HOWE and W. POURPART, both then in fine form, scored 34 runs, not out, but the tea bell rang, and play was discontinued. After tea, the party dispersed, many having to travel long distances, but all were delighted with their outing.

SEEDLING SUGAR CANES IN THE WEST INDIES.—From the *Agricultural News* we learn that the cultivation of new seedling sugar canes, as compared with the Bourbon and other varieties hitherto grown in British Guiana and elsewhere in the West Indies, shows considerable progress in recent years. From returns to hand it appears that 28,801 acres were planted in British Guiana in seedling canes in 1906-7. The area in 1905-6 was 14,743 acres, and 1904-5, 9,518 acres. Amongst the more important seedling varieties are the Demerara seedlings, B. 109 and B. 625, while two Barbados seedlings, B. 208 and B. 147, are also largely cultivated. It is pointed out that an Editorial note, which appeared in the *International Sugar Journal*, in May last (pp. 219-220), discussing the "Identity of Seedling Canes in Demerara," and stating that it was "an ascertained fact" that the seedling cane B. 208, cultivated on the well-known Diamond Plantation in Demerara, "was not the original seedling of that variety," is absolutely without foundation. Samples of B. 208 from Diamond Plantation have since been submitted to a critical examination by the Imperial Department of Agriculture for the West Indies, and it is stated that they are identical with the original seedlings of that variety raised at Barbados.

THE NATIONAL ROSE SHOW.—In connection with the Metropolitan Exhibition of the National Rose Society, which will be held on Thursday next, an enthusiastic amateur grower writes us as follows:—"To the lover of Roses all roads will lead to Regent's Park on Thursday, July 4. In the spacious and delightful gardens of the Royal Botanic Society, the National Rose Society will hold the great Rose show of the year. Success is a foregone conclusion. The National Rose Society now numbers well over 2,000 members as against 500 or 600 a few years ago, and the membership is rapidly increasing. Rose cultivation is likewise extending, not only as regards the production of specially fine flowers for the orthodox exhibition stands—and it may be said that in this respect competition is keener than ever—but in respect to the lovely decorative varieties also, which have received deservedly increased attention. On July 4, in addition to the glorious exhibition blooms, we shall see the loveliest forms of decorative Roses, climbing Roses, buttonhole Roses, groups of Roses, and arches, tables, bowls, baskets, and vases decorated with Roses. The proverbial vagaries of an English spring and early summer have excited the usual hopes and fears in the hearts of devotees, but their ardent enthusiasm will doubtless be found to have conquered difficulties, and the show will furnish the choicest results of their unsparing attention. Rose growers are looking forward to an exhibition surpassing any previous display, and one which will be of the greatest interest to every lover of the queen of flowers. The honorary secretary of the Society is Mr. EDWARD MAWLEY, Rose Bank, Berkhamsted, from whom full particulars may be obtained in regard to the show, or the National Rose Society."

SOLDIERS AS GARDENERS.—Colchester being one of the most important military stations in Britain the War Office owns a large area of land in the district. It was, therefore, considered by those in authority that some of it might be utilised to interest the soldiers in practical horticulture. The proposal originated in conjunction with a scheme for the technical instruction of soldiers, and in the hope that the knowledge gained would be useful to them after leaving the colours. Towards this end a contribution was made by the Army Council, such contribution being utilised for making a small grant to each of the original applicants for allotments to aid them in procuring seeds, erecting the necessary fences, and for the payment of an instructor, &c. Over 100 non-commissioned officers and privates applied for allotments, and at present 97 plots are under cultivation. Each plot is 1-16th of an acre, for which the sum of sixpence per month is required as rent from the men. Each cultivator is supplied with what manure is necessary, and is allowed the use of garden tools, and original applicants were given grants of money to purchase seeds, &c. A capable local gardener devotes a part of two days in each week to instructing the men by practical demonstration. Cultivation of the plots commenced on March 1, and on June 22 the plots were judged by Mr. O. G. ORPEN, Chairman of the Colchester Horticultural Society, and Mr. WM. CURTHERBERTSON, J.P., of Messrs. DOBBIE & Co., Rothesay and Marks Tey. Prizes to the number of 31 were awarded, amounting to nearly £5. They were scheduled according to the number of plots taken up by individual corps, and championship prizes were also awarded to the best of the plots taken collectively. In all the plots, writes a correspondent, Potatoes are a leading feature, and with few exceptions they look remarkably well, some of the growers already lifting their early varieties. Between the lines of Potatoes in nearly every instance winter Greens have already been planted. Peas are grown on all the plots, and they have

been sown with due regard to succession. Broad Beans, Runners and Kidney Beans are very popular. The following is a list of the crops grown on one which might be called an average plot: Peas, Potatoes, Cabbages, Beans (Broad, Runner and Kidney), Parsnips, Turnips, Beet, Carrots, Lettuces, Parsley, Tomatoes, Onions, Shallots and Celery. Some of the plots have a few flowers, such as Sweet Peas, Poppies and Nasturtiums. The general condition of the plots as regards cleanliness and neatness is remarkable, and it was impossible to find a weed in many of them on June 22. The produce is the absolute property of the cultivator. In pointing up the plots for prizes the judges had some difficulty in making their awards; the general condition of the best plots being very even and the whole testifying to the great interest taken in the work by the men. The following cultivators were awarded the championship prizes: 1st, Sergt. HADLEY, King's Own Regt.; 2nd, Pte. W. CLARKE, Queen's Regt.; 3rd, S.Q.M.S. CHISHOLM, A.P.C.; 4th, Sergt. WHITE, 2nd Northampton Regt.; 5th, Pte. VINCENT, 2nd Northampton Regt.; 6th, Q.M.S. CLARKE, R.E.; 7th, Pte. T. NEW, The Queen's Regt.; 8th, Sergt. SMITH, A.P.C.

THE HORTICULTURAL SOCIETY OF FRANKFORT-ON-THAINE.—It is recorded in the Proceedings of this Society that the commission for the care of plants by children in the schools distributed 8,840 plants amongst the scholars in ten schools. The town gardens contributed 1,000 plants.

THE YORKSHIRE GALA.—Messrs. J. Backhouse & Son, Ltd., write us as follows:—"The premier award for the best trade exhibit in the show was given to us, and the special premier award for Roses was given to Mr. Mount. From your report, it would appear that Mr. Mount was awarded the premier prize." Our representative informs us that at the time his notes were taken the only premier award mentioned in the schedule had been awarded to Mr. Mount, but we are glad to publish this additional information.

Publications Received.—*Figs and How to Grow Them.* Hugh Low & Co., Royal Nurseries, Bush Hill Park, Middlesex.

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

STRAWBERRY KENTISH FAVOURITE.—After reading the interesting note, p. 389, on the new Strawberry Kentish Favourite, I have sent you some fruits gathered from the open field, and packed as I send them to Covent Garden Market. Experienced Strawberry growers who have seen the crop on my farm have been astonished at the crop. Being an early variety, I have nearly finished picking the fruits from one bed. Those who have tasted the fruits on the farm in comparison with Royal Sovereign have pronounced Kentish Favourite decidedly superior in flavour. I have never seen any mildew on the plants, although some were planted next to a variety which were affected badly. The flower-trusses stood the frost much better than some other variety, and, although the variety does not bloom early, the fruits develop quickly, so that they are ready for harvesting first. The market growers of Strawberries are buying the runners in large quantities for planting next autumn. *W. R. Pierce, St. Dunstan's Nursery, Canterbury.* [These fruits were of extra large size and good flavour. See p. 427.—Ed.]

FRUIT PROSPECTS IN SOUTH-EAST ESSEX.—The Apple and Plum crops are very poor indeed this year. Well-established trees that bore heavy crops of Apples last year are, as is usually the case the following year, quite fruitless. Trees of the following varieties of Pears are fairly well cropped: Beurré d'Amanlis, Beurré Diel, and Louise Bonne of Jersey. Apple trees nearly three

years old from the bud, owing to the semi-tropical weather and long spell of drought which we experienced last season, made very little wood growth, consequently plenty of fruit-buds were formed and matured. These opened into fine blossom in May; the blooms being large and strong, and a fine set of fruit resulted, thinning of the fruits being necessary. The trees though so young are strong, and with few exceptions, very healthy. The varieties which are bearing so freely are Lane's Prince Albert, Allington Pippin, Devonshire Quarrenden, Bismarck, Cox's Orange Pippin, Lord Suffield, King of Tompkins County, and Worcester Pearmain. Gooseberries are very plentiful, also Black Currants and Raspberries. *H. W. Ward, Lime House, Rayleigh.*

HYDRANGEAS IN TUBS.—In reference to *F. M.'s* note, p. 374, on "Hydrangeas in tubs for garden decoration," I enclose a photograph [not reproduced.—Ed.] of a plant of *Hydrangea Hortensia*, which has flowered for the past four seasons in a tub in the garden of H. L. Clarke, Esq., Wroxham, Norfolk. There is another equally good specimen, and the plants have received no special attention beyond being given a mulching of manure in the spring when growth is starting, and an application of a fertiliser at intervals of a fortnight while they are developing their flower trusses. In autumn the tubs are placed in a motor-house that is attached to the residence, and here they remain until the following spring. *J. C., Norwich.*

SUMMER PRUNING OF FRUIT TREES.—The report on summer pruning, published in the last issue of the *Gardeners' Chronicle*, is a most interesting record, and will serve to direct attention to a subject of considerable importance. If all the results claimed for the practice, and which might be theoretically expected, could be secured, it would constitute a most valuable aid to fruit growers of all classes. Were it possible to determine the production of fruit buds with this expenditure of labour alone, an ample reward would be obtained for the outlay. Further, if the transformation of wood buds in the current season's growth into flower buds could be thus readily effected, as some appear to assume, the greatest problem in connection with fruit growing would be solved, and, given immunity from frost, insects, or diseases, the grower might regulate his crops at pleasure. It is nearly 40 years ago since my attention was first directed to this subject, and it has been a matter for study on all favourable occasions ever since, under most diverse conditions and with all kinds of fruit-bearing trees or bushes grown in the United Kingdom. The results of my observations are as follow:—(1) Definite dates cannot be fixed for the work; they must be determined by the season and the weather. It is evident the reporters, whose opinions were published, have found this difficulty, for the dates given range over a period of three months, i.e., from the first week in June to the first week in September. (2) The operation when really beneficial is mainly so in reference to specially trained and restricted trees in removing superfluous growth and permitting the maturation of wood or fruit of the current season. (3) This exposure to light and air may assist in the formation of flower buds, if these develop subsequent to the performance of the pruning. But in the majority of cases buds are already formed when the work is done, and I have never been able to obtain sufficient evidence that current year's wood buds in this stage can be transformed into flower buds the next year by any method of summer pruning or pinching. The term "good," which so many reporters employ without any qualification, probably is used in a general sense in most cases, and refers more to wall trees and general convenience than to the chief object in view. In only 13 instances out of the 150 is any special term employed, such as "very good," "excellent," or "most beneficial," and then generally without any additional remark. In nine cases, however, observations are added indicating that the operation has resulted in the production of a greater number of flower buds, and here at once the question arises "How was the increase measured and recorded?" We are all inclined to found general conclusions upon imperfect or inadequate evidence, and in no work in this error more readily committed than in gardening, because so long a period often elapses between the cause and the effect that something

FIG. 173.—HIPPEASTRUM "MRS. CARL JAY." COLOUR OF FLOWERS, PINK AND WHITE.

(For text see page 425.)

of the utmost importance may be quite overlooked or forgotten in the meantime. What evidence can be produced to show that growth buds on the current season's wood have been altered by summer pruning into fruit buds the following year? This is the critical point. The general advantages of summer pruning are admirably reviewed in the leading article on page 406, which I can confirm from my own practice, but the essence of the whole matter is contained in the question I have submitted, and replies would be both interesting and useful. *Lewis Castle.*

The excellently tabulated report from 191 gardens in the United Kingdom, printed in last week's issue of the *Gardeners' Chronicle*, affords interesting and useful reading for expert fruit-growers residing not only in England, Ireland and Scotland, but in every colony and most other parts of the world. Out of 84 reports sent from Scotland four correspondents report the results as indifferent. Out of 142 reports from various parts of England 14 record indifferent results, but eight reports from Wales are all favourable to summer pruning, while two reports out of 16 received from Ireland attach no advantage to the practice. A few out of the 21 "indifferents" express definite opinions without giving any reason for doing so. One reporter, writing from Norfolk, states that summer pruning has no effect on cropping, whilst our esteemed friend and able practitioner, Mr. W. Miller, writing from Berkshire, Warwickshire, says "that summer pruning is not much practised," that it "is unnecessary," adding that the practice "admits air and light, otherwise of little use." The remaining 170 correspondents, writing from various parts of Scotland, northern, eastern, and midland counties of England, Wales, &c., have found that summer pruning is productive of good results. Mr. George Bunyard, whose opinion should carry great weight, writing from Maidstone, says summer pruning is "most beneficial," whilst another Kentish fruit grower of note, Mr. George Woodward, pronounces the practice "very good," and Mr. W. Speed and Mr. R. Milner, writing from Denbighshire and Glamorganshire respectively, both affirm that summer pruning is very satisfactory in its results. It would be interesting and useful to learn upon what grounds the "indifferents" base their opinion as to the non-beneficial results attending the practice of summer pruning fruit trees. *H. W. W.*

HIPPEASTRUM MRS. CARL JAY.

THIS Hippeastrum (fig. 173) received an Award of Merit at the meeting of the Royal Horticultural Society on June 11, principally for its extreme floriferousness. The flower is pleasing in its colouring, which is a shade of pink, on a white ground, the pink forming a veining over the surface of the petals. Each leaf has a white band along its centre, as is present in *H. reticulatum*. A description of the plant appeared on p. 392. The variety was exhibited at the meeting already mentioned by Mrs. Carl Jay, Blendon Hall, Bexley.

SOCIETIES.

ROYAL HORTICULTURAL.

JUNE 25.—The meeting on Tuesday last in the new hall in Vincent Square, Westminster, might be almost described as a "Pæony" exhibition, such an outstanding feature did these showy flowers make among the exhibits. Many other hardy flowers, however, were presented, and there were, as usual, miscellaneous plants and flowers exhibited before the several Committees.

The ORCHID COMMITTEE's Awards to novelties included one First-Class Certificate, two Botanical Certificates, and two Awards of Merit.

The FLORAL COMMITTEE recommended 11 Awards of Merit, and the FRUIT & VEGETABLE COMMITTEE recommended Awards of Merit to a seedling Melon and Strawberry Kentish Favourite.

At the afternoon meeting of Fellows the usual election of new Fellows took place, and the Rev. Prof. George Henslow delivered a lecture on "The Peculiarities of Leaf-Arrangements."

Floral Committee.

Present: W. Marshall, Esq. (chairman), and Messrs. H. B. May, Jno. Green, Chas. E. Shea, J. T. Bennett Pöe, J. W. Barr, Walter T. Ware, R. W. Wallace, Jas. Douglas, C. Dixon, H. J. Jones, Chas. E. Pearson, W. Cuthbertson, W. P. Thomson, E. H. Jenkins, H. J. Cutbush, Geo. Paul, R. C. Reginald Nevill, G. Reuthe, J. F. McLeod, John Jennings, R. Hooper Pearson, and R. C. Notcutt.

Messrs. JAMES VEITCH & SONS, LTD., King's Road, Chelsea, showed flowering plants in great variety, including both hardy and exotic species. Many beautiful greenhouse flowers were staged by Messrs. Veitch, of which we may enumerate *Angelonis salicariæfolia*, with purple flowers, and a white variety named *grandiflora alba*; *Rhododendrons Souvenir de J. H. Mangles* and President; *Swainsonia galeifolia*, *Rodgersia pinnata*, and varieties of *Carnations*. There were also hardy plants, including *Kalmia myrtifolia*, *Salvia Souliei* (a very coarse-growing variety, with large violet flowers), *Drimys Winteri*, a very extensive collection of *Pæonies*, and an equally representative display of Spanish Irises. (Silver-Gilt Flora Medal.)

Messrs. H. CANNELL & SONS, Swanley, Kent, displayed plants of *Gloxinias*, each having a large number of flowers, vases of long-spurred *Aquilegias*; a beautiful salmon-rose-shaded *Canna* named *Frau Emma Kracht*, and excellent tuberous-rooting *Begonias*. These last-named plants were exceptionally fine, some of the more handsome being *Lady E. Malet* (salmon), *Lord Roberts* (scarlet), *Mary Lady Vivian* (salmon-pink), *Mrs. A. G. Hubbard* (scarlet), *Mrs. Matthews* (white), *Sparklet* (richest scarlet), and *Sunflower* (yellow). (Silver Flora Medal.)

Messrs. JAMES CARTER & CO., High Holborn, London, displayed *Gloxinias* in a pleasing setting of small Palms, Ferns, *Selaginellas*, &c. The plants were all unnamed seedlings, with flowers in many pretty shades of colours, and were raised from seeds sown on September 15 last.

Mr. C. W. BREADMORE, Winchester, again contributed a display of handsome bunches of Sweet Peas, all showing the very highest degree of culture, and representative of the best and newest kinds in commerce. A selection includes *Miss Audrey Crier* (pink), *Helen Lewis* (rosy-salmon), *Miss H. C. Philbrick* (blue), *Vera Jeffery* (pale pink), *King Edward VII.* (crimson), *Mrs. Collier* (yellow), *Henry Eckford* (orange), *George Herbert* (magenta), and *Phenomenal* (a pale variety with a heliotrope edge—of *Picotee* type). (Silver-Gilt Banksian Medal.)

Miss H. HEMUS, Holdfast Hall, Upton-on-Severn, showed seedling Sweet Peas of much merit. Two were distinguished by Awards, and there were other good varieties in blue, pink, cerise and other colours.

Messrs. PAUL & SON, Old Nurseries, Chess-hunt, showed Roses from the open. Sprays of a large, single, rambling variety overhung from the back of the exhibit—the name *Starlight* is not prettier than the flowers, which are white tipped with pale rose. Another having long sprays is *Buttercup*, the growth being studded with tiny yellow blooms. Both these Roses are new, and another exhibited for the first time is *Paula*, a new Tea variety—a derivative of *Marechal Niel* and *Georges Nabonnand*, but showing the influence of the former parent more largely. There were also such handsome kinds as *Lady Roberts*, *Mad. Abel Chatenay*, *Mad. Perney*, *Carmine Pillar*, *Mad. E. Resal*, &c. As a separate exhibit, Messrs. PAUL showed *Pæonies* which were equal to the best of these flowers in the Hall: *Dictamnus fraxinella*, *Verbascum olympicum*, &c. The following *Pæonies* were exceptionally fine: *Mad. de Verneille* (white), *Mad. Loise* (carmine), *Mad. Lemoine* (pink centre), *La Perle* (pink), and *Princess Mathilde*, having a creamy rosette-shaped centre, the outer petals being pink. (Silver-Gilt Flora Medal.)

Messrs. HUGH LOW & CO., Bush Hill Park, Enfield, displayed *Carnations*; especially fine was the variety *Sir Evelyn Wood* of the *Souvenir de la Malmaison* type. *Lady Rose* (rose pink) and *Nautilis* (pink) were also shown well by Messrs. Low.

Mr. JAMES DOUGLAS, Edenside, Great Bookham, Surrey, showed border Pinks in variety, most of which were raised by the exhibitor. *Morna* is one of the finest of the laced kinds, the flower is large, and has deep maroon-

crimson lacings on a white ground. Excellent is worthy this name; it has a vinous red centre and claret-coloured lacing. *Oriel* is a fringed variety. Other good kinds are *Wedgwood*, *Rainbow*, *Beauty*, *Lufra*, and *Snowdrift*.

Messrs. BEN. R. CANT & CO., Colchester, Essex, showed bunches of garden Roses, amongst which we noticed *Bellefleur*, *Gruss an Teplitz*, *Perpetual Thalia*, *Pharisaer*, *Le Progrès*, *Ards Rover*, *Dr. Campbell Hall*, &c. (Silver Banksian Medal.)

Mr. L. R. RUSSELL, Richmond, Surrey, again displayed ornamental-leaved exotic plants as at the previous meeting. (Silver Banksian Medal.)

Spanish Irises were very plentifully represented. A large collection of seedlings was displayed by Messrs. H. HOMAN & SONS, Noordwijk, Holland, the blooms being remarkably bright in appearance and fresh, although they had travelled so far. Some of the best will be found described under Awards, and other commendable kinds included "Dream," the whole flower of which is streaked with blue on a paler blue ground; *Mad. de Stael*, white with a yellow blotch on the falls; and *Sweetheart*, the yellow falls overhung the white erect standards. (Bronze Flora Medal.)

Messrs. W. BULL & SONS, King's Road, Chelsea, showed Spanish Irises and a few of the English type. *Flora* is a Spanish Iris of a pretty shade of lavender with white falls marked with yellow. *King of the Blues* is another fine thing, and *Cajanus* is the best amongst yellow kinds, although *Canary Bird* and *Kingfisher* are two commendable flowers of this shade. *Gertrude* is an English Iris of a pleasing Plum colour.

Messrs. R. WALLACE & CO., Colchester, exhibited an assortment of seasonable garden flowers and many aquatic plants. Interesting subjects noticed were *Rodgersia podophylla*, a fine plant for the water-side; *Plantago maxima*, *Linum perenne*, *Mimulus Crispum Queen*, with dark reddish-brown flowers spotted with yellow; *Pentstemon Murrayanus*, a tall species, and *P. pygmaeus*, a dwarf species, as is indicated by the name. There were also many beautiful Irises *Liliums*, *Eremuri*, *Pyrethrums*, &c. (Silver Banksian Medal.)

Mr. AMOS PERRY, Enfield Chase, Middlesex, showed a very extensive exhibit of hardy plants, amongst which were choice varieties of *Pyrethrums*, *Irises*, *Campanulas*, *Heucheras*, *Pinks*, *Liliums*, *Ostrowskia magnifica*, *Galax aphylla*, *Eremurus robustus* and other species; *Allium Schubertii*, with rose-coloured, star-like flowers on long peduncles, that formed the rays of the umbellate inflorescence; *Oriental Poppies*, &c. *Dianthus Abbotfordianus* is a charming subject for the flower garden; it has cerise-coloured flowers and a very floriferous habit. Trays of hardy *Nymphæas* found a place in the exhibit. (Silver-Gilt Flora Medal.)

Mr. C. REUTHE, Keston, Kent, had a fine array of hardy flowers, amongst which *Pæonies* were a conspicuous feature. *Pæonia arborea lutea* was shown in flower; it is a yellow-flowered *Pæony* that is somewhat rare in gardens, and not larger than a *Trollius*. Among the herbaceous kinds were *Festiva maxima* (white), *Duchess d'Namour* (white), *Carolina* (rose), *Mad. Calot* (a pale suffusion of rose), *Dog Rose* (single), and *Ceres* (white). *Kitty Reuthe* and *Mrs. Reuthe* are two handsome German Irises of Mr. REUTHE's raising. They are both of shades of lavender on white. The group also contained *Rhododendron cinnabarinum*, *Lithospermum* (*Moltki*) *petraea*, *Linaria*, *Pyrethrums*, &c. (Silver Flora Medal.)

Mr. MAURICE PRICHARD, Christchurch, Hants., displayed hardy flowers in great variety, all showing the highest form of culture and representing most of the best things in season. Hardy *Nymphæas* occupied a place in the centre of the group. (Silver Flora Medal.)

Mr. W. J. GODFREY, Exmouth, Devon, showed seedling *Delphiniums* in colours ranging from pale blue to almost purple; a number of pale coloured varieties of *Oriental Poppies*, some compact, small plants of *Solanum Wendlandii*, nicely flowering, and a dark-flowered border *Carnation* named *Mr. J. P. Bryce*.

Messrs. THOS. S. WARE, LTD., Feltham, Middlesex, exhibited a selection of herbaceous *Pæonies*, tall spike of *Delphiniums*, and *Eremuri*. In the group were also intermingled a few other hardy flowers. (Silver Banksian Medal.)

Messrs. W. CUTBUSH & SONS, Highgate, London, N., staged a very large group of perennial flowers, arranged in their usual artistic manner. Tall epergnes were requisitioned at the back to exhibit Eremuri, Delphiniums, Pæonies, and other tall subjects, and stands were also used as foils in the centre of the group, over a ground-work of Poppies, Irises, Veronica amethystina, Pyrethrums, Liliums, &c. (Silver Flora Medal.)

Messrs. BARR & SONS, 12, 13, 15, King Street, Covent Garden, London, showed numerous varieties of herbaceous Pæonies, also Spanish Irises in many of the choicer kinds, and white and other forms of Campanula persicifolia. (Silver Flora Medal.)

Messrs. KELWAY & SONS, Langport, Devon, exhibited a very large collection of Pæonies, backed with a row of their named varieties of Delphiniums. Four of the best Pæonies are Geraldine, with a yellow pompon-like centre surrounded by an outer whorl of pink petals; A. J. Hunter, a fine rose-coloured variety; Mrs. Reginald Balfour, of a paler shade of rose than the last-named; and Beatrice Kelway, a fine white flower. The Delphiniums represented the best of Messrs. KELWAY'S strain, notable kinds

flowers as Pæonies, Scabiosa, Irises, Alstroemerias, Campanulas, Delphiniums, Eremuri, Pyrethrums, &c. (Bronze Flora Medal.)

Exhibits of Alpine and hardy flowers were also displayed by Messrs. JOHN FEED & SON, West Norwood; the Misses E. & M. KIPPING, Hutton, Essex; Mr. A. R. UPTON, the Guildford Hardy Plant Nursery, Guildford, Surrey (Bronze Flora Medal); and the Misses HOPKINS, Barming, near Maidstone, Kent.

A tall Iris of pale blue or heliotrope colour, allied to *I. cypriana*, and named *Carthusiana*, was displayed by J. W. MARSHALL, Esq., Robinites, Godalming.

Messrs. J. CHEAL & SON, Crawley, Sussex, again exhibited their rose-coloured form of *Lupinus polyphyllus*.

A large group of show Pelargoniums was staged on the floor by J. A. YOUNG, Esq., Stone House, Putney (gr. Mr. G. H. Street). The plants were well cultivated, freely flowered, and represented some very pretty varieties of these plants. (Silver Flora Medal.)

Some very handsome tuberous-rooting Begonias in both double and single-flowering varieties were shown by Messrs. JOHN LAING & SONS, Forest Hill, West Norwood.

Essex, and some other counties. It produces its many-flowered inflorescences very freely, and the flowers, which are of moderate size, are of a brilliant yellow colour, with a few small, red spots on the back of the lower lip, which show through. The plants, as shown, had flowers from 12 inches to 14 inches high, and the foliage was very similar in form to that of *C. plantaginea*. The accompanying illustration at fig. 174 is reproduced from a photograph kindly supplied us by Mr. P. C. M. VEITCH, and shows the plants blooming in Messrs. Veitch's nursery in a position in which they have been planted for two years, during which time they have withstood 18 degrees of frost without receiving protection. Shown by Messrs. R. VEITCH & SON, Exeter.

Carnation The Squire.—This is a very finely-formed *Carnation* of dark heliotrope or puce colour. It belongs to the "border" section, and those who appreciate the colour will be sure to admire the contour of the flower. Shown by Mrs. BERKELEY, Spetchley.

Coleus Cordelia.—A very gross-growing variety, with large, crinkled leaves, many of which are nearly coloured red over their whole surface, with a shade of orange. Older leaves had more

FIG. 174.—CALCEOLARIA VEITCH'S HYBRID, FLOWERING IN THE OPEN, WHERE THE PLANTS HAVE GROWN FOR TWO YEARS WITHOUT PROTECTION. (See "Awards of Merit.")

being Kelway's Blue, of a deep shade of cobalt blue, Lord Hawke, a spreading flower with a deep purple sheen on a blue ground; Silver Buckle, a bell-shaped flower of a rich opal blue shade; Zinfandel, a double flower, blue in colour, with a purple centre; and Dorothy Kelway, pale blue.

Messrs. GEO. BUNYARD & CO., LTD., Maidstone, set up a fine exhibit of seasonable hardy flowers. These included most of the best plants in season, such as Pæonies, Delphiniums, Irises, Campanulas, Gaillardias, Poppies, Glaucium flavum, Phlox subulata, P. ovata, Lupines, Liliums, Roses, and a host of other pretty flowers, that required a large table for their accommodation. (Silver Flora Medal.)

Messrs. GEO. JACKMAN & SON, Woking, Surrey, staged hardy flowers. We noticed *Betonica nivea*, *Dianthus neglectus*, *Acantholimon glumaceum*, *Dracocephalum Ruyschianum*, Poppies in variety, Irises, Gaillardias, Scabiosa, and a fine batch of the red *Lilium davuricum erectum*. Elsie is a border Pink of fine form, colour, and habit.

Messrs. G. & A. CLARK, LTD., Dover, Kent, showed hardy perennial plants in flower. This extensive exhibit was furnished with a choice assortment of the best garden kinds of such

Messrs. R. VEITCH & SON, Exeter, Devon, showed flowering sprays of *Abutilon vitifolium*, *Ozothamnus rosmarinifolius*, *Buddleia Colvillei*, *Olearia macrodonta*, &c.

Messrs. THOS. CRIPPS & SONS, Tunbridge Wells, Kent, showed ornamental-leaved Maples, decorative Vines and other climbers, Clematis, *Genista sagittalis*, the golden-leaved Elder, &c.

Messrs. H. B. MAY & SONS, Edmonton, staged Carnations, *Gloriosa superba*, *Hydrangea paniculata*, and other flowering plants in a setting of rare and choice varieties of Ferns. (Silver Banksian Medal.)

AWARDS OF MERIT

were recommended to the following plants:—

Amphicome Emodi.—An old but rare *Bignoniaceae* plant suitable for cultivation in the greenhouse, or in the most sheltered positions out-of-doors in warm localities. The plants grow to about 1½ foot high, and produce rose-coloured flowers with the slightest shade of orange. Shown by Messrs. JAS. VEITCH & SONS.

Calceolaria Veitch's Hybrid.—This plant has been obtained from a cross between *C. plantaginea* and a variety of the herbaceous section. It is extremely valuable as a garden plant, having proved hardy in Devonshire, Surrey,

yellow, and less red colour. Shown by E. MOCATTA, Esq. (gr. Mr. Stephenson), Woburn House, Exeter.

Ervum gracile.—A perennial herb of the natural order Leguminosae, having narrow leaves and purple, Vetch-like flowers, produced on inflorescences generally carrying about ten blooms each. The species of *Ervum* are now included in the genus *Vicia*. Shown by Mr. MAURICE PRICHARD.

Iris Mr. W. T. Ware.—A variety of *I. hispanica*; colour of flowers yellow, with orange blotch on the falls.

Iris King of the Whites.—Of the same type as the preceding variety. The flowers are very large and pure white, except for the bright yellow blotch on the falls.

Iris P'Unique.—A Spanish Iris, with erect, blue standards, and blue and white falls, the falls being white except for the yellow in centre. The Irises named above were shown by Messrs. H. HOMAN & SONS, Noordwijk, Holland, and the Awards were made for the unusual size and quality of the flowers.

Papaver orientale Jennie Mawson.—A very large flower of a salmon shade of rose colour, with a large purple blotch on each segment.

The flowers open sufficiently wide to display themselves well. The plants have a good, vigorous habit, and the flowers will last well after having been packed, the segments being very persistent. Shown by Messrs. MAWSON BROS., Windermere.

Sweet Pea Evelyn Hemus.—A distinct variety with creamy-white flowers, having rose-coloured margins to the petals. The blooms are of large size, and three or four are produced on the stalk.

Sweet Pea Carmine Paradise.—This flower is coloured brilliant carmine. It has an erect standard and possesses good quality. Both the varieties were shown by Miss H. HEMUS, Upton-on-Severn.

Orchid Committee.

Present: J. Gurney Fowler, Esq. (in the chair), and Messrs. Jas. O'Brien (hon. sec.), Harry J. Veitch, De B. Crawshaw, J. Wilson Potter, Francis Wellesley, F. J. Hanbury, W. Boxall, A. A. McBean, H. A. Tracy, W. H. White, H. G. Alexander, W. Bolton, J. Charlesworth, W. Cobb, A. Dye, F. M. Ogilvie, R. G. Thwaites, H. Ballantine, W. A. Bilney, H. T. Pitt, and C. J. Lucas.

Some excellent examples of choice and rare Orchids were presented by amateurs, and notably a small group staged by Major G. L. HOLFORD, C.I.E., C.V.O., Westonbirt, Tetbury (gr. Mr. H. G. Alexander), the central plant in the exhibit being a magnificent specimen of the best white type of *Odontoglossum crispum*, grown from a single pseudo-bulb, which has developed into a grand plant carrying 12 flower-spikes, bearing altogether 88 flowers. A Cultural Commendation was voted Mr. Alexander, the grower. With it were *O. crispum Zoroaster*, a large, rosy-lilac flower with some reddish spotting; *Lælia tenebrosa*, "Walton Grange variety," still unapproached in its class; *L. tenebrosa*, "Westonbirt variety," a beautiful and very darkly-coloured form; *Lælio-Cattleya Herode*, "Westonbirt variety" (*L.-C. elegans* × *C. O'Brieniana*), an attractive rosy-lilac hybrid; and flowers of *Sobralia Holfordii*, *S. macrantha alba*, *S. Amesiana*, and *S. Veitchiana*. (Silver Flora Medal.)

No less remarkable from a cultural point of view was the stately *Lissocilus giganteus* shown by the Hon. WALTER ROTHSCHILD (gr. Mr. A. Dye), and which forms a worthy companion to the fine *L. Horsfallii* so well shown by Mr. ROTHSCHILD on March 6 last year. (See Awards.)

Sir TREVOR LAWRENCE, Bart., Burford (gr. Mr. W. H. White), showed a selection of finely-grown rare species, including the pretty *Epidendrum* (*Barkeria*) *spectabile*, with many spikes of large white and rose-coloured flowers; a fine example of *Cryptophoranthus Dayanus*, *Maxillaria ochroleuca*, and others, some of which received Awards.

Messrs. CHARLESWORTH & Co., Heaton, Bradford, staged a very extensive group, for which a Silver-Gilt Flora Medal was awarded. A fine feature was made by a large number of excellent form of *Lælio-Cattleya Canhamiana*, the class having white sepals and petals being grouped together, as were those with rose segments. At one end of the group was a selection of *L.-C. Fascinator*, and, arching over from the back were sprays of the white *Phalaenopsis amabilis* *Rimestadtiana*, *Odontoglossum Wilckeanum*, *O. crispum*, *Oncidium macranthum*, &c. Among the blotched forms of *Odontoglossum crispum* were several of the *Heatonense* type illustrated in the *Gardeners' Chronicle*, June 22, p. 409. Other good things noted were *Acineta Hrubyana*, with stout racemes of white flowers carrying purple labellums; *Cirrhaea viridis*, the singular *Ornithocephalus grandiflorus*; the violet-coloured *Warszewiczella discolor*, a good *Cattleya Mossiae alba*, and many hybrids.

Messrs. HUGH LOW & Co., Bush Hill Park, Enfield, were awarded a Silver Banksian Medal for a group in which were handsome *Cattleyas*. The flowers of *C. Mossiae* "King of Siam" are pure white, and *C. M. Arnoldiana*, Smee's variety, is also a white form, with slight marbling of rose on the lip. *Masdevallia Peristeria*, and other *Masdevallias*, various *Odontoglossums*, including a light-coloured form of *O. Loochristiense*, *Cypripedium callosum* *Sanderæ*, *C. Maudiae*, the singular *Cirrhopetalum Thouarsii*, and some well-flowered *Oncidium macranthum* were also displayed.

Messrs. MOORE, LTD., Rawdon, Leeds, secured a Silver Banksian Medal for an interesting group, which included the handsome *Cœlogyne asperata* (see Awards), *Maxillaria rufescens*, *Promenæa xanthina*, *Cypripedium callosum* *Sanderæ*, *Trichopilia crispata marginata*, *Erides Fieldingii*, *Cochlidia Noezliana*, *Masdevallia Boecking hybrid*, and other *Masdevallias*, &c.

R. I. MEASURES, Esq., Cambridge Lodge, Camberwell (gr. Mr. Smith), exhibited a group which was remarkable for the number of pretty species it contained, including *Pleurothallis Barberiana*, with gnat-like flowers; *P. immersa*, with white, feather-like sprays of flowers; a selection of *Masdevallias*, including *M. radiosa*, *M. Carderi*, *M. triaristella*, *M. stella*, *M. Chimæra*, *M. Chestertonii*, &c.; also *Miltonia vexillaria*, good *Oncidium macranthum*, *O. Krameri*, *Saccolabium ampullaceum*, and *Stelis tristyla*. *Cypripedium Curtisii viridis* has labellums of a dull green colour, slightly tinged with purple; *Lælio-Cattleya Endymion* (*L. tenebrosa* × *C. Gaskelliana*), &c. (Silver Banksian Medal.)

FRANCIS WELLESLEY, Esq., Westfield, Woking (gr. Mr. Hopkins), sent *Lælio-Cattleya Hippolyta* "Prince of Orange," a specially brightly-coloured variety, with reddish-orange-coloured sepals and petals, and a claret purple lip; *Lælio-Cattleya Miss Leese* (*L. tenebrosa* × *C. Wm. Murray*) has white sepals and petals suffused with lilac. The lip is purple, changing to rose in the front.

J. GURNEY FOWLER, Esq., Glebelands, South Woodford (gr. Mr. J. Davis), sent *Lælio-Cattleya C. G. Roebing*, "Glebelands variety," a compact, white flower, with the front of the lip bright ruby-purple, and with a broad, pure white margin.

Miss WILLMOTT, Warley Place, Great Warley, Essex, sent a fine specimen of *Sobralia Veitchii*, Warley variety. The sepals are cream-white, the petals tinged with primrose; the yellow lip having a lilac shade on the front lobe.

J. WILSON POTTER, Esq., Elmwood, Park Hill Road, Croydon (gr. Mr. W. H. Young), sent *Cypripedium Wiertzianum*, "Wilson Potter's variety," a flower larger in all its parts than the ordinary form and finely marked.

W. THOMPSON, Esq., Walton Grange, Stone, Stafford (gr. Mr. W. Stevens), sent *Odontioda Bradshawiae*, Walton Grange variety, finer than the original type and of a bright-red colour, the margins of the sepals and petals being coloured dark red.

H. S. GOODSON, Esq., Fairlawn, Putney (gr. Mr. G. E. Day), again showed *Odontoglossum Wilckeanum* "H. S. Goodson." The flower is generally cream-white, but the sepals, save the tips, are chocolate-brown, and the petals blotched with the same colour. The plant was finely grown, and bore a very strong flower-spike.

Mr. W. HOLMES, The Gardens, Hey House, Tonge Moor Road, Bolton, sent *Cypripedium Euryale*.

Messrs. STANLEY & Co., Southgate, showed several very distinct forms of *Cattleya Mossiae*, including the variety *Sunbeam*, the flower of which is white, with a slight purplish marking on the lip; and another named *Heliotropium*, also white, but suffused with a lavender shade.

Messrs. J. & A. A. McBEAN, Cooksbridge, showed a fine variety of *Cattleya Mendelii*, the pure white *C. Mossiae* *Wagneri*, *C. M. Reinckiana*, and two fine *Odontoglossum crispum*s.

R. G. THWAITES, Esq., Streatham (gr. Mr. Black), showed *Odontoglossum Pescatorei* *Grand Duchess*, probably the largest and best form of *O. Pescatorei*. The flowers are as large as those of *O. crispum*, and of circular outline, white, with a rose flush on the sepals, and some purple spots in front of the yellow crest of the lip. The same gentleman also displayed a fine white *O. crispum*, with some spotting on the sepals.

AWARDS.

FIRST-CLASS CERTIFICATE.

Lissocilus giganteus, from the Hon. WALTER ROTHSCHILD, M.P., Tring Park (gr. Mr. A. Dye). A species from the Congo of very large size, and which was first flowered by Sir TREVOR LAWRENCE, Bart., in 1888; a figure and description of this plant is given in the *Gardeners' Chronicle*, May 19, 1888, pp. 616-7. The leaves are bright green and plicate; the stout inflorescence rises to a height of 7 feet or more, and bears on the upper third of the flower stalk about thirty

flowers and flower buds. The flowers, which are more than 3 inches across, have inconspicuous sepals of a greenish hue tinged with purple, the conspicuous part being the broadly ovate petals, which are of a bright rose-pink colour; and the large three-lobed lip of a rosy-lilac tint with some darker lines on the disc, and a purple shade on the front. It is a noble plant, and under the semi-aquatic treatment during the growing season, devised by the Hon. WALTER ROTHSCHILD so successfully for *L. Horsfallii*, it thrives admirably. The inflorescence elongates as the upper flower-buds develop, and in its native habitat it is said to often attain a height of from 15 to 16 feet.

AWARDS OF MERIT.

Cirrhopetalum gracillimum, from Sir TREVOR LAWRENCE, Bart. (gr. Mr. W. H. White). An elegant little species with slender scapes bearing umbels of pretty Indian-red flowers, the lateral sepals being thread-like and about 2 inches in length and decurved so as to form a parasol-like head. The extraordinary structural arrangement of the central and smaller parts well repays examination with a lens.

Calogyne asperata, from Messrs. MOORE, LTD., Rawdon, Leeds. A large-growing species often imported from Borneo, but seldom seen in flower. The plant bore a strong inflorescence with many large cream-white flowers that have brownish-orange markings on their lips.

BOTANICAL CERTIFICATE.

Placoglottis Lowii (syn. *C. Lowii*), from the Hon. WALTER ROTHSCHILD (gr. Mr. A. Dye). A singular Malayan species with purple-tinted pseudo-bulbs and leaves and erect pubescent scape bearing very singularly-constructed, but not conspicuous flowers, the lateral sepals of which are curiously arranged, cream colour with a brown blotch on each.

Hartwegia purpurea, from Sir TREVOR LAWRENCE, Bart. (gr. Mr. W. H. White). A dwarf-growing plant with stem-like pseudo-bulbs, having fleshy, dull green leaves that are spotted with red, and bearing a slender inflorescence with a cluster of rose-coloured flowers on the apex.

Fruit and Vegetable Committee.

Present: Geo. Bunyard, Esq. (chairman), and Messrs. H. Parr, Geo. Kelf, J. Davis, H. Markham, Alex. Dean, P. D. Tuckett, C. G. A. Nix, J. Jaques, Owen Thomas, W. H. Divers, W. Poupart, A. H. Pearson, Thomas Coomber, Jas. Vert, Chas. Foster, P. C. M. Veitch, G. Reynolds, and A. R. Allan.

This committee again found little to occupy its attention.

The chief exhibit was one of 15 Queen Pine-apples, a fruit now rarely exhibited from British gardens. These were sent by Lord LLANGATOCK, The Hendre, Monmouth (gr. Mr. Thos. Coomber), and were extremely good specimens of this choice fruit. (Hogg Medal.)

Messrs. DOBBIES & Co., Rothesay, N.B., and Mark's Tey, Essex, showed 24 varieties of Potatos from the open garden. They represented a very clean, well-cultivated sample, and, considering they were dug from the open, they were of remarkable size. The varieties included such standard sorts as *Ideal*, *Southern Queen*, *Duke of York*, *Sharpe's Victor*, *Early Puritan*, and *Crimson Beauty*. (Silver Banksian Medal.)

Messrs. JAMES VEITCH & SONS, LTD., King's Road, Chelsea, showed pot plants of a rather coarse-growing Tomato named *New Dwarf Red*. It is a free-cropping variety, with fruits of a rather more than medium size.

Several seedling Melons were presented for Awards, and a well-preserved sample of *Apple Barnack Beauty* was sent for naming.

AWARDS OF MERIT.

Melon Eminence.—An oval fruit of medium size, with a beautiful yellow exterior that is pleasingly netted. The flesh is white, and is said to possess a very fine flavour. Shown by Mr. MCKELLAR, Royal Gardens, Frogmore.

Strawberry, Kentish Favourite.—No fruits of this variety were found after the Committee had risen, but from a sample sent us direct by Mr. W. R. Pierce, St. Dunstan's Nurseries, Canterbury, we are enabled to furnish the following description. The fruits are large, having much of the shape and appearance of *Royal Sovereign*, but are slightly darker in colour. Most

of the fruits we received were of unusually large size, wedge-shaped, and although the flavour is not equal to that of some older varieties, it is agreeable, and superior to that of Royal Sovereign. Mr. Pierce informs us the variety is a good cropper, capable of withstanding mildew, and that the fruits ripen very early in the season. Shown by Messrs. HUGH LOW & Co., Bush Hill Park, Enfield.

NATIONAL CHRYSANTHEMUM.

JUNE 20.—The members of the National Chrysanthemum Society held their annual outing on the above date, when, by permission of Jeremiah Colman, Esq., a visit was paid to Gatton Park, Surrey. The grounds and gardens were inspected by the visitors. The Orchid houses were a very great attraction, and Mr. Bound, the head gardener, succeeded in arousing the interest of every member of the party by his description and explanation of the habits and peculiarities of the plants. A close inspection was also made of the celebrated Marble Hall, which was originally erected by the late Lord Monson. Gatton was, in earlier times, one of the pocket boroughs, returning two members to Parliament, and the Town Hall, which would certainly not accommodate more than eight or ten people, is interesting. Although some of the best of the cattle were away at the various shows, there were still sufficient left to show the great interest taken by Mr. Colman in cattle breeding. After an inspection of the grounds, the party was conducted in brakes to Redhill, where lunch was served at the Warwick Hotel. The chairman of the society, Mr. Thomas Bevan, presided, and at the conclusion proposed the health of Mr. Jeremiah Colman, coupling with it the name of Mr. Bound, who had acted as guide to the party throughout. After lunch the party enjoyed a drive round Norwood Hill, Leigh, Reigate Heath, etc., returning to Redhill in time for tea at 6 o'clock. Another drive back to Mersham in time to catch the train for London Bridge completed the day's programme.

ANSWERS TO CORRESPONDENTS.

* * * The Editor will be glad to receive, for consideration, large photographs of horticultural subjects, suitable for forming Supplementary Illustrations to this Journal.

CANNA FAILING TO GROW: W. H. W. It would appear that the roots were kept in unsuitable conditions during last winter, and that they were without life when you potted them up in the spring. If this had not been the case, the plants would certainly have shown some indication of growth, even if they failed afterwards. The injury during winter may have been caused by cold, or by the presence of too much water in the soil, which sometimes happens through the dripping of water from the stages.

CARNATIONS: H. O. E. The seedlings appear to us to possess much merit, and judging from the great length and rigidity of the flower stems we should have supposed they were raised wholly, or partly, from American varieties. Most of the flowers are shades of carmine or pink, and are very pretty, but scarcely so full as meets with general appreciation. You should get together three good plants of each variety and show them in full flower before the Floral Committee of the Royal Horticultural Society.

CATERPILLARS: P. McG. These could not be found. Send fresh specimen.

COST OF FUEL FOR HEATING TWO RANGES OF FRUIT AND PLANT HOUSES, FITS, &c.: Eky-Ark. The probable annual cost of heating your two ranges of glasshouses, pits, and sheds, by means of some 1,300 feet of 4-inch (mostly), and 3-inch hot-water piping attached to two separate boilers, a Gold Medal and a Chatsworth, would be the purchase of about 90 tons of coke in order to heat both apparatuses efficiently during a period of 12 months. This coke, at a cost of 13s. 6d. per ton, would amount to £60 15s. In this calculation due allowance is made for the low temperatures necessary to be observed in the fruit houses (two Peach houses and two vineries), in which Chrysanthemums, Arum Lilies (*Richardia africana*), Deutzias and bedding plants are

wintered. A considerable saving in the fuel bills might be effected in many gardens, by the exercise of more careful stoking on the part of those whose duty it is to do the work, such, for instance, as the keeping of the furnace bars and flues clear from accumulations of ashes and small coke, which cause them to become choked, resulting in a sluggish draught. The banking up of the fires with ashes should be done sufficiently early on the mornings of bright days to allow sun heat alone to cause the atmospheric temperature to rise to the desired degree in the houses. It is a wasteful practice to push the fires first thing in the morning, without considering what the weather may be like. In the case of sunshine appearing the temperature becomes too high, and to decrease the heat it is then necessary to open the furnace door, and let the heat out into the stoke hole. This would be proof that more fuel had been put into the furnace than was necessary.

DOUBLE FLOWERS FAILING TO PRODUCE SEED: R. B. The reason that double flowers produce little or no seed is because the doubling has arisen through the conversion of stamens into petals, which therefore usually lose their functional capacities. It frequently happens, however, that not all the stamens in a double flower are thus modified, and in such cases the flowers may be capable of producing a small quantity of seed.

EXAMINATION IN HORTICULTURE: J. L. Apply to the Secretary of the Royal Horticultural Society, Vincent Square, Westminster, London.

FUNGUS ON LAWN: J. S. The Mushrooms are the "Fairy Ring Champignon" *Marasmius Oreades*. The only thing to do is to dig out the patches and relay the turf, as the mycelium pervades the soil, and the area will grow larger every year.

GLASSHOUSES ON SIDE OF HILL: B., Limited. We do not think there need be any insuperable difficulty in heating the houses with one boiler, even though they are on different levels. It will, however, be necessary to place the boiler below the level of the lowest house, and lay the flow pipe through this first, in order that the house which is situated highest will be at the farthest extremity from the boiler.

GLOXINIAS: Regular Reader. We suspect the trouble is caused by insufficient ventilation, but cannot be sure owing to the specimen being so badly packed that the soil has mixed with, and adheres to, the partly decayed foliage.

HEN AND CHICKEN DAISY: G. H. The abnormal form of Daisy you send is not uncommon; a number of adventitious buds have developed on the inflorescence and have given rise to secondary capitulum. It is an example of lateral floral proliferation of the inflorescence.

LILY OF THE VALLEY CROWNS: C. G. H. You do not send any information in respect to the plants. No mycelium and no trace of fungus disease is present in the crowns. Every information should be afforded to enable us to arrive at a correct solution.

NAMES OF FRUITS: G. E. P. Apple D'Arcy spice.

NAMES OF PLANTS: K. S. L. 1, *Atragene alpina*; 2, *Vinca minor*.—E. C. C. D. 2, *Thesium linifolium*; 3, *Ranunculus flammula*.—Rubrum. 1, *Nepeta Mussinii*; 2, variety of same species; 3, *Dianthus Plumarius*; 4, specimen not received; 5 and 6, *Saxifraga* sp.—W. J. *Psoralea pinnata*.—A. B. 2, *Cratægus Crupgalli arbutifolia*; 4, *Vaccinium corymbosum*; 5, *Acer pennsylvanicum*.—W. P. 1, *Cratægus punctata*; 2, *Amelanchier canadensis* var. *ovalis*; 3, *Alnus glutinosa aurea*.—T. W. R. *Zelkova crenata*.—Fresco. 1, *Scilla peruviana*, dark variety; 2, *Thalictrum flavum*; 3, *Erinus alpinus* probably, specimen too much withered for accurate determination; 4, *Dianthus plumarius* var.; 5, *Saxifraga Andrewsii*; 6, *S. taygetea*.—T. C. *Botrychium lunaria*, a Fern.—M. A. P. 1, *Berberis Thunbergii*, very finely fruited; 2, *Polemonium coeruleum*; 3, *Cassinia fulvida* (syn. *Diplopappus chrysophyllus*); 4, *Ligustrum vulgare*, variegated variety; 5, *Ceanothus thyrsiflorus*; 6, *Achillea Ptarmica*.—C. M. 1, *Erigeron alpinus*; 2, *Sidalcea malvæflora*; 3, *Cistus monspeliensis florentinus*; 4, *Thalictrum minus*; 5, *Spiræa Ulmaria*; 6, *Spiræa Aruncus*.—A. P. N. 1, *Scilla peruviana* (b'ue);

2, *Sisyrinchium striatum*; 3, next week.—T. H. 1, *Sedum Rhodiola*; 2, not recognised; 3, *Lychnis viscaria*.—A. R. T. 1, *Maxillaria rufescens*; 2, *Trichopilia laxa*; 3, *Oncidium barbatum*; 4, *Brassia brachiata*; 5, *Bifrenaria Harrisonia*; 6, *Ada aurantiaca*.—R. A. H. 1, *Akebi quinata*; 2, *Calycanthus floridus*; 3, *Muscus Comosum*; 4, *Iris*, flower withered; 5, *Syring Emodi*; 6, *Funkia Sieboldii*.—F. R. 1, *Campanula* species; 2, *Lilium monadelphum*; 3, *Lilium Thunbergianum*; 4, *Lilium Martagon*; 5, *Campanula Hendersonii*.—W. P. S. F. We do not undertake to name varieties of Roses. Send them to a nurseryman who has means of comparing them with similar flowers.—L. H. 1, *Neottia nidus-avis*; 2, next week; 3, *Habenaria bifolia*; 4, *Cephalanthera grandiflora*.

NECTARINE FRUITS: P. McL. The disfigurement appears to have been caused by the punctures of some small insect.

ONIONS: J. C. There is no fungus present, but the roots are attacked by microscopic creature known as Eelworms. These being already in the plants it is next to impossible to kill them without causing injury to the plants. Some growers have obtained comparatively good results from the injection of small quantities of bisulphide of carbon into the soil. "Vaporite," a proprietary article manufactured by Mr. Strawton, has also been recommended.

PEACHES: A. E. The fruits received are perfectly healthy, though far from ripe. That they are not more forward can only be explained by describing your forcing treatment as very slow. If you want to hasten the ripening, you should employ more heat which is not injurious after the stoning stage is passed. We certainly think that both the borders you mention must, by this time, require water, but there is nothing in the specimens to show that the trees have already suffered from drought.

POULTRY: Ouum. Write to the Editor of *Poultry*, 12, Mitre Court Chambers, Fleet Street, London, E.C.

PLOUGH FOR SUBSOIL: A. J. M. It is only at farm sales in Kent or Sussex, as a rule, that old turn-wrest ploughs are to be obtained, and most of them are too heavy for two horses. An advertisement for a light secondhand plough in the *Sussex Express*, Lewes, would possibly elicit offers, as there are many old ploughs lying about unused. A strong ridging-plough without its breasts, to follow an ordinary plough, would do the work moderately well, but possibly you could hire a proper ridging-plough locally. The small American cultivating machines are capable of standing a great strain, and they are valuable for cultivating between fruit trees and bushes. You might purchase a "Planet Junior" cultivator that will work the subsoil when divested of some of its attachments.

RAINFALL: A. W. Write to the authorities at the Meteorological Office, Victoria Street, Westminster, who will supply you with the information you desire.

ROSE LEAVES: Juvenile. The condition in the leaves is caused by the cold weather, which makes them very liable to the attack of mildew and other fungus diseases. Syringe the trees with water containing a little flowers of sulphur, and when the weather becomes warmer the trouble will probably cease.

SPOTTED LEAVES OF SYCAMORE: H. C. The spots on the upper surface are galls caused by the punctures of some minute insect. Not at all uncommon on various trees.

VIOLET LEAVES: P. H. L. The leaves are affected by a fungus disease, the growth of which is favoured by shade and a condition of dampness, such as exist in the small spaces between rows of big Currant bushes. If you have some plants which are not contaminated with the disease, it will be best to burn those which are now in the fruit plantation, and cultivate the healthy plants in a position where the air is less stagnant and more light is present.
